Puget Sound Energy, Inc.	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Idaho Power Company	Yes	We generally agree, however, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.

Organization	Question 4:	Question 4 Comments:
SMUD	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables. Reference 3.5.1: In cases where an SPS is deployed to reduce thermal overloads such that flows are brought within established facility ratings, but, for a short duration (seconds) until it is fully executed, the facility flows exceed the established rating, is that considered a violation or an acceptable engineering judgment that facilities are judiciously being brought to operate within ratings? Or, should the facility owner ensure establishment of a documented rating even for the short duration of seconds?
Progress Energy Florida, Inc.	No	PEF does not disagree with the conditions described in Requirements R3.5.1, R3.5.2 and R3.5.3 when taken in particular contexts. PEF, however, is compelled to check "no" for this question due to the fact that no specification has been made as to when such CAPs can be applied. PEF feels that the CAPs specified (as well as the curtailment of Firm Transactions and Non-Consequential Load) should be allowed following any N-1 event, and also as system adjustment actions in between the two events of a P6 event. Given that no such specification has been made here, PEF objects to the wording, and suggests that the language be modified to clarify that the application of these CAPs are allowable after N-1 events and in between the two events of Event P6.
Sierra Pacific Power Company / Nevada Power Company	Yes	We generally agree, however, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Black Hills Corporation	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Arizona Public Service Co.	Yes and No	We generally agree, however, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other

Organization	Question 4:	Question 4 Comments:
		Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest moving R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Florida Power and Light	No	The sub-requirements of R3.5 are not clear as to whether the conditions apply to before or after generator run-back/tripping and mixes together N-1 and N-2 contingencies. In addition, the phrase "sustainable, stable, operating condition" in R3.5.3. is ambiguous as to whether it means the system is secure (prepared for the next contingency), or the system is maintained in a stable operating condition which is sustainable but not secure.
Exelon Transmission Planning	Yes and No	We agree that manual and automatic generation run-back and tripping should be allowed in these situations. We do not agree with the portion of R3.5.2 that states that non-compliance would result if the action were to violate statutory or regulatory requirements. A local governmental body could impose a restriction that would then trigger NERC compliance issues without independent or sufficient review. Other regulatory entities have their own enforcement mechanisms. It should be clear that SPSs, by definition, are allowed for other purposes than generation runback or tripping (such as system reconfiguration with automated breaker operation).
SRP	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Tucson Electric Power Company	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
SERC Dynamics Review Subcommittee	Yes	Generation run-back and tripping should be allowed and the proposed sub-requirements are appropriate.

Organization	Question 4:	Question 4 Comments:
Modesto Irrigation District	Yes	Comments: We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Midwest ISO	Yes and No	Under the subrequirement of R3.5.2 it may not be possible for the PC/TP to determine whether the safety, equipment, regulatory or statutory requirements are violated without collaboration with the Transmission Owner and/or the Generator Owner. Therefore, if this subrequirement is retained it should be amended to include the following sentence: "Applicable Transmission Owners and/or Generator Owners shall collaborate with the PC/TP in determining whether such action would violate safety, equipment, regulatory or statutory requirements".
Tri-State Generation and Transmission Association, Inc.	Yes	Agree with the described corrective actions, but wonder whether the sub-requirements R3.5.1 - R3.5.3 must be specifically listed.
Tri-State G&T	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Southern Company Transmission	No	Generation run-back and tripping should be allowed and most of the proposed sub-requirements are appropriate. However, R3.5.2 is overly broad. We suggest that regulatory and statutory requirements should be deleted from R3.5.2.
NERC and Regional Coordination	No	Delete R3.5.2 as redundant. The limit data provided by the asset owners is expected to ensure that safety, equipment, regulatory and statutory requirements are met. For example to require the PC to ensure that equipment is not at risk would require the PC to make financial decisions that belong to the asset owner (e.g. the owner may be willing to exchange loss of equipment life for short term financial gains).R3.5.3 - the term sustainable, stable condition is not defined. Further the

Organization	Question 4:	Question 4 Comments:
		maintenance of such a state is beyond a PC's capability.
ColumbiaGrid	Yes	We generally agree, however, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
IESO	Yes and No	We agree with the conditions stipulated in R3.5.2 and R3.5.3 but do not agree with R3.5.1. This is one of the performance objectives that the use of manual and/or automatic generation run-back/tripping is intended to achieve, and it is already stipulated in Table 1. Suggest to remove this condition.
Southern California Edison	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
North Carolina Electric Membership Corp	Yes and No	The generation run-back/trip should not put any load or firm transfer at risk of also being harmed. Maybe this is implied within the conditions required.
ERCOT System Planning	No	The requirement is unclear whether runback is allowed if the conditions are met or if runback is allowed to meet the conditions. What is the need for generation run-back/tripping if all facilities are within their Facility Ratings? Many times the run-back/tripping of units, such as wind farms, is necessary to remove a post-contingency overload associated with these units. The protection scheme includes the run-back/tripping to allow these units to generate at higher levels pre-contingency.
Florida Reliability Coordinating Council, inc	No	R3.5.1 ? This requirement should be clarified to state that all facilities shall operate within their Facility Ratings before, during and after system adjustments including generation adjustments.R3.5.2 ? How can an entity demonstrate that it is not violating this requirement.. The SDT should indicate the type of regulatory and/or statutory requirement that this requirement trying to address (i.e., FERC, EPA, etc.)?. Otherwise, the FRCC recommends removing R3.5.2.R3.5.3 ?The SDT should clarify this requirement to define what is meant by sustainable and stable. Sustainable and stable may not necessarily be the same as

Organization	Question 4:	Question 4 Comments:
		being in a secure condition (ready for the next possible event).
Alberta Electric System Operator	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest R3.5 and R3.4.3 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
Orlando Utilities Commission	No	The requirement R3.5.1 is not clear. If the intent is that following a single or multiple contingency facilities are within their ratings before, during and after the generation adjustment it's should be specified that way. "All facilities shall operate within their facility ratings prior to, during, and after the generation adjustment". Also I am unclear on how I would prove that I am not violating and safety or statutory requirements, that seems to be attempting to prove a negative since it is not specific on which requirements. Maybe ?Not violating any known safety and statutory requirements? if it is necessary to have this part. However since any real statutory and safety requirements have their own enforcement mechanism it is unnecessary to have the NERC auditor monitor these in addition to the existing monitors. I am not sure on the definition of sustainable? Is it a system that requires no further adjustment to be within it's long term ratings? Or is it a system that is prepared for the next event (Secure)?
Entergy Services, Inc.	Yes and No	The intent seems reasonable, but the wording needs work. There needs to be consistent verb usage. All 3 sub-bullets need to use "shall" instead of "would" and "is."
US Bureau of Reclamation	Yes	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables.
BPA Transmission Reliability Program	No	R3.5 is not a requirement, but an allowed action in order to meet performance criteria. Therefore, the statement about generation run-back/tripping in R3.5 should be moved to become part of the notes in the Performance Tables and not part of the requirements text. The conditions described under R.3.5.1 through R.3.5.3 are covered elsewhere in the standards and should be removed from this section. Since R3.5 and R5.4 contain some similar wording, also see comments relating to R5.4 under Item 2, above.
Response: The SDT agrees and has eliminated these conditions in Sub-requirements R3.5.1, R3.5.2 and R3.5.3 for Contingency events as well as similar conditions in Sub-requirements R5.4.3.1, R5.4.3.2 and R5.4.3.3 for Stability events in the third draft. Accordingly, the SDT has modified Sub-requirement R3.5 for		

Organization	Question 4:	Question 4 Comments:
Contingency events and relocated it to become Sub-requirement R2.6.1 – bullet #4. Likewise, the SDT has modified Sub-requirement R5.4.3 for Stability events and relocated it to become Sub-requirement R2.6.1 – bullet #3. **R2.6.1. – bullet #3:** Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations. **R2.6.1. – bullet #4:** Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate Steady State performance violations.		
Lafayette Utilities System	No	Requirement R.3.5 states that generation run-back is allowed as a response to single or multiple contingencies, as long as certain conditions are met. Lafayette's concern is that the allowance for generation run-back is not limited to generation owned by the Transmission Planner or under the Transmission Planner's direct operational control. For that reason, the language could be interpreted to permit reliance (for planning purposes) on redispatch of generation owned by third-party generation owners that is undertaken in compliance with Reliability Coordinator directives during a Transmission Loading Relief event. During the SDT conference call held on August 26, 2008, the SDT representative stated that the team did not intend that R.3.5 would permit a Transmission Planner to rely on third-party generation redispatch, and that the intent was only to permit reliance on run-back (redispatch) of generation owned by or under the direct control of the Transmission Planner. Lafayette believes the language of R.3.5 needs to be clarified to state in express terms the limitation intended by the SDT. Reliance on third-party redispatch should not be permitted unless a Transmission Planner has entered into a contractual arrangement with the generation owner authorizing such use.
Response: The SDT agrees that if a Transmission Planner does intend to rely upon third party generation as an option to meet this requirement then the Transmission Planner's contractual arrangements between that Generation Owner and the Transmission Operator must be in place. However, the SDT does not believe that this needs to be stated as a Requirement in this Standard.		
Ameren	Yes	R3.5.1 should be modified as "All Facilities shall be operating within their applicable Facility Ratings, including the use of short-time emergency ratings."
E.ON U.S. Transmission Planning	Yes and No	R3.5.1 Is this the intent? ? Following Single Contingency events, Transmission configuration changes and redispatch of generation can be simulated to return the system to Normal Rating provided that all Facilities shall be operating within their Emergency Rating.
Response: As stated in Footnote 10 of Table 1, planned System adjustments are allowed, unless precluded in the Requirements, to keep Facilities within the Facility Ratings, if such adjustments are executable within the time duration applicable to the Facility Ratings. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within		

Organization	Question 4:	Question 4 Comments:
applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
American Transmission Company	No	We generally accept this text, but would like the Facility Rating reference to include the applicable time frame (see response to Question 2.)
Response: As stated in Footnote 1 of Table 1, planned System adjustments are allowed, unless precluded in the Requirements, to keep Facilities within the Facility Ratings, if such adjustments are executable within the time duration applicable to the Facility Ratings.		
PPL EnergyPlus	Yes and No	My concern is that some TSPs over-use RAS and at some point, system improvements must take place. The best approach is a collaborative effort of all stakeholders (esp. operations folks) to prevent abusing RAS. Possibly R3.5 could tie to or be put under an Requirement that involves collaboration with stakeholders.
Response: The SDT has modified Sub-requirement R3.5 for Contingency events and relocated it to become Sub-requirement R2.6.1 – bullet #4. Likewise, the SDT has modified Sub-requirement R5.4.3 for Stability events and relocated it to become Sub-requirement R2.6.1 – bullet #3. Collaboration between the Transmission Planner and the Planning Coordinator is referenced in Requirements R5, R6, and R7. **R2.6.1. – bullet #3:** Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations. **R2.6.1. – bullet #4:** Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate Steady State performance violations.

Response: Thank you for your response.		

5. The SDT has modified the modeling requirements. Some commenters expressed concern that the modeling requirements contained in Requirement R1 of the first draft of TPL-001-1 were either duplicative of the requirements in the MOD standards, or to the extent new modeling requirements were proposed, that the appropriate venue for such modeling requirements would be the MOD standards. The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has incorporated these additional requirements with the intent that they will be removed from the TPL standard when they are incorporated into the MOD standards at a later date.

The SDT has also modified proposed modeling requirements contained in Requirement R1 of the first draft of TPL-001-1 based on industry comments and moved these requirements to Requirements R9 through R14 in the second draft for ease of removal later on. Furthermore, in response to industry comments, the SDT has separated the modeling requirements into individual requirements for each responsible entity. Do you concur with the modifications reflected in Requirements R9 – R14? If not, please state why and/or suggest specific changes..

Summary Consideration:

In response to industry comments, the SDT has removed requirements R9-R14 and enhanced requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. Any comments received from the industry on MOD standards will be forwarded to NERC staff for inclusion in NERC Reliability Standards Development Projects 2010-04 Modeling Data and 2010-05 Demand Data.

The following requirements have been changed due to industry comments:

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~ Models for the Planning Assessment shall represent:

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as:

- Transmission Lines
- Generators
- Circuit breakers
- Reactive Power devices

- Protection System equipment
- Control devices
- New technologies

R1.1.3 Real and reactive Demand of Load

R1.1.4 Firm Transmission Service

R1.1.5 Interchange

R1.1.6 Network resources required to supply Load

R2.1.4 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.

Organization	Question 5:	Question 5 Comments:
Dominion - Electric Transmission Planning	Yes and No	For requirements R9, R12, R13, the wording should be changed from ..."shall provide its respective Planning Coordinator with modeling information ..." to "shall provide its respective Planning Coordinator and Transmission Planner with modeling information ..."
NPCC	No	With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail, such as distribution network detail, is also required. It is also important to note that some Canadian Provinces do not "classify" their load mix using "industrial, commercial and residential" designations but their load modeling is sufficient, accurate and granular enough to simulate system response. Add to the last sentence of R9 through R14 the following phrase, "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator."
TVA System Planning	No	TVA provides the following comments: " Distribution Provider" in R9 should be replaced with "Load Serving Entity." Also in R9, is the expected mix of load to be presented individually or as a total of commercial, residential, and industrial loads? Would requiring this mix of load forecasts also result in a change to any MOD or FAC requirements dealing with

Organization	Question 5:	Question 5 Comments:
		load forecasts?" Transmission Planner" in R10 should be "Transmission Service Provider." Is this requirement also in MODs? In R11, R12, and R13 suggest adding "Transmission Planner" to "Planning Coordinator". In R13, Resource Planner may not have knowledge of Reactive Power devices and new technologies.
Manitoba Hydro	Yes and No	R1: Requirement R1 places the obligation for maintaining a model on the PC/TP. While the PC/TP can maintain data for its system(s), the models generally used for planning assessments are regional models developed and maintained by the Regions. Could the SDT explain its expectation of the scope and responsibilities of the model to be maintained? R9-R14: This TPL draft includes Requirements R9 to R14 that impose obligations on the PC/TP that differ from the way planning models are compiled in accordance with the existing MOD standards. Manitoba Hydro comments on R9 to R14, as follows: R9: Agree. R10: The TSP is the Functional Model entity that should provide the Firm Transmission Service data and Interchange Schedules to the PC. R11: Agree R12: Agree R13: We disagree that the Resource planner is responsible for Reactive Power devices. Can the SDT explain what they consider should be included in new technologies? R14: While we agree that the TP can provide the PC data of planned faculties, isn't this data already required to be provided under the MOD standards?
Transmission Agency of Northern California	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
OPUC	Yes	R9. — 14 can be addressed in the MOD standards.
Pacific Gas and Electric Co.	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective

Organization	Question 5:	Question 5 Comments:
		tariffs, and should not be included again in the proposed TPL-001-1 Standard.
US Army Corsp of Engineers, Northwestern Division	Yes and No	R12 requires the GO to provide "modeling information" for planned outages and/or changes to the generator owner facilities to the Planning Coordinator for each year of the Transmission planning horizon. You need to be more specific with what type of "modeling information" you are requesting from the GO. The GO may have the model parameters for their equipment but this doesn't mean that they have expertise necessary to model system responses or even run a model simulation. So if you are expecting the GO to perform model simulations for each year of the Transmission planning horizon the GO may not have the expertise necessary to comply. Recommend you clarify what you mean by "modeling information".
Public Service Company of New Mexico	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Puget Sound Energy, Inc.	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
ITC Holdings: ITC, METC, ITC Midwest	Yes and No	In general, we approve and concur with these requirements. The requirement R9 that the distribution providers submit the expected mix of residential, commercial, and industrial loads is necessary to model the dynamic behavior of loads as required in R 2.4.1. This requirement will better model the dynamic response of loads to voltage changes. In R10, the Transmission Planner provides OASIS type information. The TSP should provide this not the TP. R-13 ? Reactive Power Devices and new technologies belongs under every entity, i.e., Distribution Planners should be included as a provider of reactive power devices as well as Resource Planner and Transmission Planner.
Idaho Power Company	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Hydro-Québec TransEnergie (HQT)	No	With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load

Organization	Question 5:	Question 5 Comments:
		cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail such as distribution network detail is also required. It is also important to note that some Canadian Provinces do not "classify" their load mix using "industrial commercial and residential" designations but their load modeling is sufficient, accurate and granular enough to simulate system response. Add to the last sentence of R9 through R14 the following phrase, "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator."
Sierra Pacific Power Company / Nevada Power Company	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Black Hills Corporation	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Florida Power and Light	No	The requirement that “all projected firm transfers modeled” (appropriate for the load level being studied) currently in the TPL Standards does not appear in the proposed standard. Does the SDT feel that Transmission Planners should have unlimited latitude in deciding which types of power transfers to assume in their reliability studies? R9. is not an appropriate requirement as the distribution provider will in many cases not know the exact mix of load types at each ?transmission node? The meaning of “transmission node” is unclear, is this substation? R11. is unclear as to what is meant by “consideration given to spare equipment strategy.” What is the appropriate consideration for compliance? What facilities are required to have a spare equipment strategy for compliance? Maintenance outages and times for all BES equipment are not likely to be scheduled or known throughout the entire planning horizon. Rather than specifying "for each year of the planning horizon" it should be limited to "if specifically known”. The Resource Planners identified in R13. should know about future generation additions and retirements as well as expected range DSM capabilities but would not generally know about reactive power devices or new technologies. Reactive power devices or new technologies should be removed from R13.
CenterPoint Energy	No	We believe the SDT should have reflected the views of most commenters in this revised draft. Requirements R9 through R14 are overly prescriptive and do not solve an actual problem. Furthermore, we are concerned about requirement

Organization	Question 5:	Question 5 Comments:
and CPS Energy		"creep" where standards include new requirements appropriately addressed in other standards (in this case, the MOD standards) because a different SDT believes the approved standard is inadequate. To clarify our main premise that the excess, misplaced requirements do not solve an actual problem, we believe one would need an extensive imagination to conjure a scenario where insufficient modeling by transmission planners in the subject matter addressed by requirements R9 through R14 have contributed or are reasonably likely to contribute in any meaningful way to a significant reliability event. In summary, we concur with the majority of commenters from the previous draft that R9 through R14 should be deleted. We also believe R1.1 is hopelessly unrealistic. In fact, we are concerned it is counter-productive and more likely to degrade reliability than improve it. R1.1 discourages transmission planners from revising inaccurate, speculative, or outdated modeling data by imposing new documentation burdens and compliance liability. We recommend that R1.1 be deleted.
SRP	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Tucson Electric Power Company	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in addition to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
SERC Dynamics Review Subcommittee	No	For R9 the LSE should provide the load forecast instead of the DP. For R9 - R14, It is not clear that the specification of data flow appropriate for both RTO and non-RTO situations because there are significant differences in the role of planning coordinator. For example: 1) Who builds and manages the base cases? Shouldn't the data be submitted to this entity? 2) According to the definition provided in this standard, the Planning Coordinator is ?The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and protection systems.? Additionally, we recommend the TPL SDT write a SAR to get the data related changes into the MOD standards or adding it the issues to be considered by the drafting team in the development plan under project number 2010-04 otherwise it will be difficult to remember to include these items in the revised MOD standards.
Modesto Irrigation District	Yes	Comments: While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the

Organization	Question 5:	Question 5 Comments:
		respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Arkansas Electric Coop. Corp.	No	R9. I disagree with providing the mix of industrial, commercial and residential, especially within a 90 day period. It is difficult enough to be able to develop a forecast must less try to quesstimate the mix of the loads.R9 through R14 -- the timing requirement should be tied to the regions model development schedule and not 90 days. The 90 days is too restrictive and not practical however model data should be updated at least annually.
Midwest ISO	No	Since the Transmission Planner has the primary model building responsibility it makes sense to have them aggregate model building information. Therefore, requirement R9 should have the Distribution Provider providing the Transmission Planner and Planning Coordinator with modeling information for real and reactive load forecast? etc. The data of R10 such as firm TS data may not be known by the Transmission Planner (ofter a TO in the RTOs). Also the language implies that there are more than one BA under a TP, also not a typical arrangement in an RTO/ISO. A hierarchical approach might be more appropriate such that the Distribution Provider, the Transmission Provider, and the Transmission Owner supply the data they control to the Transmission Planner and the Planning Authority so that those entities can build models they need to meet the study requirements of the standard.
Tri-State Generation and Transmission Association, Inc.	Yes	We are pleased the SDT pulled out these Requirements. Does the SDT plan to leave them in the standard as notes until they can be incorporated into other standards where they belong? In R11, the term "long-term" is not clear.
Tri-State G&T	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
AEP	Yes	However, although the responsible entities listed for each individual requirement are correct from a functional model (compliance) perspective, in actual practice the data flow may not (and in many instances does not) follow the paths outlined in this draft. For example, the node loads, scheduled interchanges, generation models, facility additions, etc., are all provided to the Transmission Owner (TO), since it's the TO that typically builds the planning models for their transmission footprint and then provides those models to the Transmission Planner and Planning Coordinator. Therefore, the Transmission Owner should be added as a recipient of this type of data.
Austin Energy	No	Requirements R9 through R14 should be deleted and re-introduced later as part of a change to MOD standards. R1.1 imposes burdensome documentation requirements which will likely become a disincentive for revising modeling data and

Organization	Question 5:	Question 5 Comments:
		should be deleted.
Lakeland Electric	No	It is sufficient to direct the TP or PC to obtain and include the appropriate data outlined in R9 through R14 in their respective model cases. The proposed addition of R9-R14 just adds more evidential paperwork requirements to the TP or PCs plate.
Southern Company Transmission	No	R9 needs to be clarified that the forecast is based on expected mix of residential, commercial, and industrial loads, but that this mix does not have to be supplied.
Brazos Electric Power Cooperative, Inc.	Yes	R9-R14 do not belong in this Standard. Adding requirements in the wrong location only adds to the confusion by forcing review of more Standards by other less relevant entities and causing additional burden by insuring the requirements match between Standards for the SDT. R1.1 should be deleted. Tracking all those changes (outages, etc?) is unreasonable and will essentially be unenforceable, for if the data is not tracked, how will anyone know it is not tracked?. Requiring large amounts of documentation that provide no additional benefit or causes undo burden will result in fewer studies or effort placed into proper study.
ColumbiaGrid	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Southern California Edison	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
Northeast Utilities	No	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.
North Carolina Electric Membership Corp	Yes	We would like to add a couple of items for clarification. 1) Planning Coordinators and Transmission Planners should make it clear to LSEs, DPs and GOs as to what extent they model loads, reactive devices, and generators and not just rely on FAC-001, FAC-002 or the entities Facility Connection Requirements document to convey that information. 2) If requirements 9 through 14 are to be removed at a later date, then the SDT should be required to initiate the

Organization	Question 5:	Question 5 Comments:
		appropriate action or SAR before its disbanding to insure this happens.
ERCOT System Planning	No	ERCOT recommends that R1.1 be deleted. ERCOT shares the opinion of some that R1.1 is counter-productive and more likely to degrade reliability than improve it. R1.1 discourages transmission planners from revising inaccurate, speculative, or outdated modeling data by imposing new documentation burdens and compliance liability. Adding additional requirements to document changes to data required in requirements R9 through R14, MOD-010, and MOD-012 could induce an atmosphere of using inaccurate data to eliminate the need to document a needed change. Furthermore, it is believed that all modeling requirements should exist in a Modeling standard not a performance standard.
Duke Energy	Yes	In order to ensure these requirements move to the MOD standards, the TPL SDT is encouraged to write a SAR to get the data related changes into the MOD standards or add it to the issues to be considered by the drafting team in the development plan under project number 2010-04.
Central Maine Power Company	No	a. With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail such as distribution network detail is also required. b. Add to the last sentence of R9 through R14 the following phrase, "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator."
New York Independent System Operator	No	With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail such as distribution network detail is also required. Add to the last sentence of R9 through R14 the following phrase, "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator."
Alberta Electric System Operator	Yes	While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.

Organization	Question 5:	Question 5 Comments:
FirstEnergy Corp.	No	FE does not support the modeling requirements within the TPL standard and suggest that the SDT remove these requirements. This standard should be viewed on a premise that a valid and appropriate system model exist so that the fundamental focus of the standard is as stated in its purpose statement "Establish Transmission System planning performance requirements... to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions." If the R9 through R14 requirements remain, we offer the following comments: R9 - In requirement R9, the DP is to provide nodal load projections and include the expected mix of industrial, commercial, and residential Loads. System planning software can not presently accommodate this level of detail along with other load codes/classifications that may already be in use; i.e. municipal load, rural electric cooperative load, etc. Is the intent to require this information in models built and maintained by industry, i.e. MMWG? R10 - The TP does not have access to Interchange Schedules and resources required to supply Load for each of its Balancing Authority. This information may need to be provided by the Resource Planner or some other appropriate entity.
US Bureau of Reclamation	Yes	Comments: While we agree with separating R1 to form R9 through R14, we believe that R9 (modeling information for real and reactive load forecast data) should be applicable to Load Serving Entities (LSE) instead of (or in additional to) the Distribution Provider. In any case, this type of exchange of load information is already covered in MOD Standard or in the respective tariffs, and should not be included again in the proposed TPL-001-1 Standard.
BPA Transmission Reliability Program	No	Requirements for data gathering and load modeling belong in the MOD Standard and not in TPL-001-1. Requirements for dynamic load models should not be specified at this time, because the models have not been developed yet or approved by the RRO (also see comments regarding R2.4.1 under Item 2, above).

Response: In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent:

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as

Transmission Lines

Organization	Question 5:	Question 5 Comments:
Generators Circuit breakers Reactive Power devices Protection System equipment Control devices New technologies **R1.1.3** Real and reactive Demand of Load **R1.1.4** Firm Transmission Service **R1.1.5** Interchange **R1.1.6** Network resources required to supply Load		
Los Angeles Department of Water and Power	Yes	See the comment from WECC
Response: The SDT did not receive any specific comments from WECC.		
National Grid	No	a. With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail such as distribution network detail is also required. b. Add to the last sentence of R9 through R14 the following phrase, "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator." c. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R10 to read as follows: R10. Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for Firm Transmission Service data, Interchange Schedules and resources required to supply Load for each of its Balancing Authorities for each year of the Transmission planning horizon, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator.

Organization	Question 5:	Question 5 Comments:
		d. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R11 to read as follows R11. Each Transmission Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for Transmission equipment for each year of the Transmission planning horizon with consideration given to spare equipment strategy, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator. e. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R12 to read as follows: R12. Each Generator Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for generation equipment for each year of the Transmission planning horizon, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator. f. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R13 and R14 as follows:R13. Each Resource Planner shall provide its respective Planning Coordinator with the modeling information for new planned facilities for each year of the Transmission planning horizon including but not limited to generators, Reactive Power devices, and new technologies, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator.. [Violation Risk Factor: TBD] [Time Horizon: TBD] R14. Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for new planned facilities for each year of the Transmission planning horizon including but not limited to Transmission Lines, circuit breakers, Reactive Power devices, Protection System equipment and control devices, and new technologies, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator. [Violation Risk Factor: TBD] [Time Horizon: TBD] g. Planned and long-term outages are two fundamentally different concepts and should be treated separately. Planned and Long-Term outages should be defined. Define how planning events in Tables 1 and 2 are associated with each type of outage (e.g. P4, P5, or P6). Should there be specific contingency descriptions associated with long-term outages? Define length of a "Long Term" outage. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon.
MidAmerican Energy Company	No	MEC disagrees with the approach of temporary requirements because of the problems that arise due to conflicting or uncoordinated standards (e.g. conflicting requirements between FAC-010-1 and TPL-002-0). We suggest the drafting team submit SARs to make the desired changes in the appropriate MOD standards. However, if these requirements are retained than we suggest the following few changes to R9-R14: The R9 wording on providing "the expected mix of industrial, commercial, and residential loads" should be dropped as the representative mix is difficult to quantify and verify while the benefit to representing the mix is unproven versus normal regional dynamic load representation practices. Many regions already convert normal steady state powerflow loads to standard mixes of, constant MVA, constant current, and shunt admittances which accounts for dynamic behavior. If the SDT decides not to drop these words, the MRO recommends "the expected mix of industrial, commercial, and residential loads" be changed to "the forecasted mix of industrial, commercial,

Organization	Question 5:	Question 5 Comments:
		and residential loads”. In R9 through R13 the responsible entities should be giving their information to the Transmission Planner in addition to the Planning Coordinator. In R10, revise the text to: "Each Transmission Service Provider shall provide ?" In R11, is the text referring to "known planned outages" and "known long term outages"? What is the distinction that is meant to be made between the two specified types of outages? In R12, revise the text to: "? modeling information for planned facilities changes, known planned outages ?". Also, is the text referring to "known planned outages" and "known long term outages"? What is the distinction that is meant to be made between the two specified types of outages? In R13, revise the text to: "? for planned facilities changes for each year of the Transmission planning horizon including but not limited to generators, and new technologies ?". This wording broadens the meaning from simply "new" facilities to also include any "changes" to existing facilities. In R14, revise the text to: "? for planned facilities changes for each year ?". This wording broadens the meaning from simply "new" facilities to also include any "changes" to existing facilities.
MRO NERC Standards Review Subcommittee	No	The MRO disagrees with the approach of temporary requirements because of the problems that arise due to conflicting or uncoordinated standards (e.g. conflicting requirements between FAC-010-1 and TPL-002-0). We suggest the drafting team submit SARs to make the desired changes in the appropriate MOD standards. However, if these requirements are retained than we suggest the following few changes to R9-R14: In R9, revise the text to: "? load forecast data for at least the coincident peak of each year ?" The R9 wording on providing "the expected mix of industrial, commercial, and residential loads" should be dropped as the representative mix is difficult to quantify and verify while the benefit to representing the mix is unproven versus normal regional dynamic load representation practices. Many regions already convert normal steady state powerflow loads to standard mixes of, constant MVA, constant current, and shunt admittances which accounts for dynamic behavior. If the SDT decides not to drop these words, the MRO recommends "the expected mix of industrial, commercial, and residential loads" be changed to "the forecasted mix of industrial, commercial, and residential loads”. In R9 through R13 the responsible entities should be giving their information to the Transmission Planner in addition to the Planning Coordinator. In R9, revise the text to: "? load forecast data for at least the coincident peak of each year ?"In R10, revise the text to: "Each Transmission Service Provider shall provide ?" In R11, is the text referring to "known planned outages" and "known long term outages"? What is the distinction that is

Organization	Question 5:	Question 5 Comments:
		meant to be made between the two specified types of outages? In R12, revise the text to: "? modeling information for planned facilities changes, known planned outages ?". Also, is the text referring to "known planned outages" and "known long term outages"? What is the distinction that is meant to be made between the two specified types of outages? In R13, revise the text to: "? for planned facilities changes for each year of the Transmission planning horizon including but not limited to generators, and new technologies ?". This wording broadens the meaning from simply "new" facilities to also include any "changes" to existing facilities. We suggested removing the reference to Reactive Power Devices because these devices would not be owned by Resource Planners. In R14, revise the text to: "? for planned facilities changes for each year ?". This wording broadens the meaning from simply "new" facilities to also include any "changes" to existing facilities.
LCRA TSC	No	R-11 states that "Each Transmission Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for Transmission equipment." This is typically achieved through outage coordination between the individual Transmission Operators and the System Operator. More clarification may help by defining the difference between planned outages and long-term outages as they are used in R-11. This may be an Operations standard versus a Planning standard requirement.
NERC and Regional Coordination	No	R9 - Reactive load forecasts are not generally provided by distribution provider to the Transmission Planner.R11 - The requirements for providing “long term outages” to the Planning Coordinator is vague. What is a “long term outage” and do I need to plan for it? I think the right answer is only if it is expected to occur over the period that the TP establishes their critical system conditions. SDT should initiate the appropriate SAR prior to disbanding.
American Transmission Company	No	We disagree with the approach of temporary requirements because of the problems that arise due to conflicting or uncoordinated standards (e.g. conflicting requirements between FAC-010-1 and TPL-002-0). We support the approach of developing appropriate MOD standards SARs to make the desired changes. However, if these requirements are retained than we suggest the following few changes to R9-R14.In R9, revise the text to: "? load forecast data for at least the coincident peak of each year In R10, revise the text to: "Each Transmission Service Provider shall provide "In R11, is the text referring to "known planned outages" and "known long term outages" What is the distinction that is meant to be made between the two specified types of outages In R12, revise the text to: "? modeling information for planned facilities changes, known planned outages ?". Also, is the text referring to "known planned outages" and "known long term outages"? What is the distinction that is meant to be made between the two specified types of outages

Organization	Question 5:	Question 5 Comments:
		In R13, revise the text to: "? for planned facilities changes for each year of the Transmission planning horizon including but not limited to generators, and new technologies ?". This wording broadens the meaning from simply "new" facilities to also include any "changes" to existing facilities. We suggested removing the reference to Reactive Power Devices because these devices would not be owned by Resource Planners. In R14, revise the text to: "for planned facilities changes for each year ?". This wording broadens the meaning from simply "new" facilities to also include any "changes" to existing facilities.
Florida Reliability Coordinating Council, inc	No	R9 through R14 ?R9 through R14 should not be addressed in this TPL Standard. Requirements R9 through R14 should be included in future revisions to the MOD standards. If R9 through R14 remain in the Standard, then the following comments are appropriate: R9 ? Recommend adding ?and season (as defined by the Planning Coordinator)? after ?? load forecast data for each year? .Recommend adding ?(as defined by the Planning Coordinator)? after ?Transmission nodes? to allow the Planning Coordinator to appropriately define the term Transmission node. Recommend deleting ?including the expected mix of industrial, commercial, and residential Loads,? from the requirement since this information is not required by Transmission Planners or the Planning Coordinator. Many distribution providers will not know the mix of load type for a given Transmission node. R11 ?Recommend the removal of ?with consideration given to spare equipment strategy,? from this requirement. We feel that the consideration of spare equipment strategy would be better suited in an operating horizon standard (TOPs) rather than in the TPL standard. The term ?long-term outage? in this requirement is vague and the text ?and long-term outages? should be eliminated. The FERC language in Order 693 P-1725 states ?Accordingly, the Commission directs the ERO to modify the planning Reliability Standards to require the assessment of planned outages consistent with the entity’s spare equipment strategy.? There is no mention of ?long-term outages? in conjunction with spare equipment strategy. R12 ? Recommend rewording as follows: ?Each Generator Owner shall provide its respective Planning Coordinator with modeling information for known planned generator outages for each year of the Transmission planning horizon, within ninety days of a request for such information.” The language ?long-term outages for generation equipment? is vague and unclear as to what is a long-term outage and what specific type of generation equipment should be considered. R13 ? Propose adding ?and any changes to existing plans? after ?new planned facilities? as shown below: ?Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for new planned Facilities and any changes to existing plans for each year of the Transmission planning horizon??
NSTAR Electric	No	1. With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load

Organization	Question 5:	Question 5 Comments:
		cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail such as distribution network detail is also required. 2. Add to the last sentence of R9 as follows "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator." 3. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R10 to read as follows: "R10. Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for Firm Transmission Service data, Interchange Schedules and resources required to supply Load for each of its Balancing Authorities for each year of the Transmission planning horizon, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator." 4. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R11 to read as follows:"R11. Each Transmission Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for Transmission equipment for each year of the Transmission planning horizon with consideration given to spare equipment strategy, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator." 5. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R12 to read as follows:"R12. Each Generator Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for generation equipment for each year of the Transmission planning horizon, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator." 6. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R13 and R14 to read as follows:"R13. Each Resource Planner shall provide its respective Planning Coordinator with the modeling information for new planned facilities for each year of the Transmission planning horizon including but not limited to generators, Reactive Power devices, and new technologies, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator.. [Violation Risk Factor: TBD] [Time Horizon: TBD] R14. Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for new planned facilities for each year of the Transmission planning horizon including but not limited to Transmission Lines, circuit breakers, Reactive Power devices, Protection System equipment and control devices, and new technologies, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator.. [Violation Risk Factor: TBD] [Time Horizon: TBD] " 7. Planned and long-term outages are two fundamentally different concepts and should be treated separately. Planned and Long-Term outages should be defined. Define how planning events in Tables 1 and 2 are associated with each type of outage (e.g. P4, P5, or P6). There should be specific contingency descriptions associated with long-term outages.

Organization	Question 5:	Question 5 Comments:
		Define length of a "Long Term" outage. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon.
ISO New England Inc.	No	a. With respect to R9 "including the expected mix of industrial, commercial and residential loads", this provision may be inadequate to be practically useful. The potential issues include the variation in end-use load mix through the daily load cycle, seasonal load composition variations, and the ability to translate these end-uses into reasonable and useful steady-state and dynamic load models. It is important to understand how the information will be used and how much additional detail such as distribution network detail is also required. b. Add to the last sentence of R9 through R14 the following phrase, "within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator." c. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R10 to read as follows: R10. Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for Firm Transmission Service data, Interchange Schedules and resources required to supply Load for each of its Balancing Authorities for each year of the Transmission planning horizon, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator. d. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R11 to read as followsR11. Each Transmission Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for Transmission equipment for each year of the Transmission planning horizon with consideration given to spare equipment strategy, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator. e. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R12 to read as follows: R12. Each Generator Owner shall provide its respective Planning Coordinator with modeling information for known planned outages and long-term outages for generation equipment for each year of the Transmission planning horizon, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator. f. Flexibility is needed to conform with the requirements of the specific Planning Coordinator. Suggest changing R13 and R14 as follows:R13. Each Resource Planner shall provide its respective Planning Coordinator with the modeling information for new planned facilities for each year of the Transmission planning horizon including but not limited to generators, Reactive Power devices, and new technologies, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator.. [Violation Risk Factor: TBD] [Time Horizon: TBD] R14. Each Transmission Planner shall provide its respective Planning Coordinator with modeling information for new planned facilities for each year of the Transmission planning horizon including but not limited to Transmission Lines, circuit breakers, Reactive Power devices, Protection System equipment and control devices, and new technologies, within ninety days of a request for such information or as otherwise described in procedures established by the Planning Coordinator.

Organization	Question 5:	Question 5 Comments:
		[Violation Risk Factor: TBD] [Time Horizon: TBD] g. Planned and long-term outages are two fundamentally different concepts and should be treated separately. Planned and Long-Term outages should be defined. Define how planning events in Tables 1 and 2 are associated with each type of outage (e.g. P4, P5, or P6). Should there be specific contingency descriptions associated with long-term outages? Define length of a "Long Term" outage. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon.

Response: In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

The SDT agrees that the wording regarding modeling of outages is confusing. In response the SDT has eliminated Requirement R11 and included a new Requirement R1.1.1 to require modeling of planned outages of generation and Transmission Facilities when they are specifically known.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent:

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as

Transmission Lines

Generators

Circuit breakers

Reactive Power devices

Protection System equipment

Control devices

New technologies

R1.1.3 Real and reactive Demand of Load

R1.1.4 Firm Transmission Service

Organization	Question 5:	Question 5 Comments:
R1.1.5 Interchange **R1.1.6** Network resources required to supply Load		
Gainesville Regional Utilities	Yes and No	I agree with the approach you are taking concerning this modeling data. I understand that "long term outages" for transmission and generation elements refer to a time frame greater that one year. But I am unclear if the "known planned outage" refers to the same time frame or does it apply to a normal scheduled maintenance type outage of less that one year. Are these "shorter that one year" outages better handled by sensitivity studies since they are normally during an non-peak seasons of the year? Again, the smaller utilities should provide all the requested data to the RRO, but should only have to answer to issues involving their elements discovered at the RRO level.
Response: The SDT agrees that the wording regarding modeling of outages is confusing. In response the SDT has eliminated Requirement R11 and included a new Requirement R1.1.1 to require modeling of planned outages of generation and Transmission Facilities when they are specifically known. **R1.1.1** Planned outages of generation and Transmission Facilities, if specifically known		
JEA	Yes and No	R9. JEA does not agree that the Transmission Planners should have the responsibility to perform load development or sanity checks on the DP's forecasted real and reactive loads based upon superfluous information like the customer mix. Also, JEA recommends adding language that gives the Planning Coordinator the option to require the forecast by season. R10. JEA agrees R11. JEA recommends that R11 be split into two functional requirements: (A) the provision of known planned outage information, and (B) the provision of "potential long-term forced outages of transmission equipment where readily available spares are not identified". JEA can support requirement (A), but believes that requirement (B) should be part of an operating horizon standard (TOP?) where the availability of spares and spare equipment strategies can be refined in a responsive manner as the opportunities evolve. JEA does not believe that the industry should overbuild its system for the possibility of a rare "low probability" equipment failure event will occur and no reasonable replacement alternative will exist in the world. R12. Need to define long-term outages R13. JEA agrees R14. JEA agrees
Ameren	No	We consider the proposed requirements R9-R14 to be largely a duplication of the MOD standards and do not agree that they belong in the proposed TPL-001-1. We would propose that a reference to the MOD standards would be more appropriate so as not to create a double-jeopardy compliance situation. If it is determined that the requirements R9-R14

Organization	Question 5:	Question 5 Comments:
		need to stay, the proposed standard needs to reflect the existing data flow processes and consider who builds the models, which is the Transmission Planner, and not the Planning Coordinator. According to the definition provided in this standard, the Planning Coordinator is "The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and protection systems." In our case, the Transmission Planner receives: a) load forecast (real and reactive) information from the Distribution Planner or Load Serving Entity, b) transmission ratings/impedance/topology(outage) information from the Transmission Owners, c) generation ratings/capabilities/outage information from the Generation Owners, and d) designated network resources (existing and future), as well as external obligations, from Resource Planners. The Transmission Planner develops powerflow and corresponding dynamic models from this information including load magnitude and distribution, generation dispatch, and net scheduled interchange, and provides the models or modeling components to the Reliability Coordinator and Planning Coordinator. Other organizations may have similar problems with data flow processes as specified in R9-R14.We view the R9 requirement of the proposed TPL-001-1 for the Distribution Provider to provide real and reactive load forecast data, including load mix information, to conflict with R1.4 of MOD-013-1 which has the RRO as setting the requirement for the dynamic load data. R10 needs to be modified to reflect the RTO activities related to the coordination and sale of Firm Transmission Service, which is not a Transmission Planning activity.R11 needs to be modified to drop the "spare equipment strategy". This is not a modeling issue and should be covered in standard TOP-002-2 (see R1 and R6).R13 needs to be modified to drop the "Reactive Power devices and new technologies" because Resource Planners typically do not know about these devices. The Transmission Planner or Owner may be the more appropriate entity. We view R14 as an extension of Standards MOD-010-0, MOD-011-0, MOD-012-0, and MOD-013-0.
Exelon Transmission Planning	Yes and No	R11 shouldn't include consideration of a spare equipment strategy. All known planned and long-term outages of transmission equipment should be included regardless of the spare equipment strategy.
IESO	Yes and No	A. R9: Agreed B. R10: Holding the TP to provide modeling information on Firm Transmission Service, (a TSP's role), Interchange Schedules (also a TSP's role), and resources required to supply Load for each of its Balancing Authorities (Resource Planner's role) may not be appropriate. In fact, the TP relies on others to provide this set of information for developing its own study model. We suggest to change the responsible entities to these specific entities; or if the TP is required to provide the PC with the model, then there should be requirements in other standards to obligate these other entities to provide the TP with the needed information. C. R11: The phrase "with consideration given to spare equipment strategy" is vague (not enforceable or measurable) and does not appear to add anything to the required product which should already have the spare strategy and capability taken into account when outage plans are developed. We suggest to remove this phrase. If this was retained, the follow on question is why R12 doesn't have a similar requirement (note that a generator outage may not be due to maintenance of the generator itself; it could be due to outages to step-up transformers, breakers or switches for which spares may be

Organization	Question 5:	Question 5 Comments:
		carried). D. R12: Agreed. E. R13: We are not sure what purpose to include "and new technologies" would serve if such technologies do not result in the provision of generators and/or reactive sources which are already covered. Further, this is vague to determine what constitutes "new technologies" and hence this is not enforceable or measurable. We suggest to remove this term. F. R14: Same comment as in R13 on "new technologies".

Response: In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

The standard's wording regarding "spare equipment strategy" has also been revised and removed from the modeling requirements. Requirement R2.1.5 now addresses how a Transmission Planner's "spare equipment strategy" should be considered in Transmission planning.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent:

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as

- Transmission Lines
- Generators
- Circuit breakers
- Reactive Power devices
- Protection System equipment
- Control devices
- New technologies

R1.1.3 Real and reactive Demand of Load

Organization	Question 5:	Question 5 Comments:
R1.1.4 Firm Transmission Service **R1.1.5** Interchange **R1.1.6** Network resources required to supply Load **R2.1.4** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.		
Progress Energy Florida, Inc.	No	PEF as a general rule believes that Requirements R9-14 can and should be addressed in a MOD Standard. Individual comments on particular ones that PEFs sees as problematic are as follows:R9: This requirement is problematic in its present wording. As worded it would appear to infringe upon the outlined process regarding provision of load forecast data as stipulated in PEFs Attachment K document, mandated to be included as an Attachment to our Tariff per FERC Order 890. In PEF's Attachment K, load forecast data, as submitted by all entities responsible for providing such data for PEF native load, must be submitted by January 1 of each year. Implementation of R9 would thus set in place two binding regulatory processes for a situation in which only one is needed. Furthermore, the requirement uses the term "transmission node", a term which is ambiguous and not easily applicable in the electric utility business. Terms such as "feeders", "substations" or "delivery points" might be more appropriate.R11: PEF appreciates the consideration given with the term "known planned outages", given that specific dates for planned outages in the long-term planning horizon are often difficult to know. This point concludes, however, with the addition of the phrase ?with consideration given to spare equipment strategy?, and PEF does not understand what is meant by this term nor why it is given special consideration in a discussion of planned outages. Spare equipment is just as crucial, if not more so, in the event of an unplanned outage. Furthermore, consideration of spare equipment strategy is already handled as part of PEF's planning processes and as part of the existing TPL Standards. PEF therefore requests that the phrase "with consideration given to spare equipment strategy" be removed from R11.R13: PEF is unsure as to the meaning of "for each year of the Planning horizon". PEF would point out that if from one planning cycle to the next, the modeling of a particular planned generator has not changed, the Resource Planners should not have to re-submit the same data over and over again on an annual basis. Additionally, PEF asserts that its Resource Planners are not involved in the development or implementation of Reactive Power devices or new technologies, and therefore requests that these specifications be removed.
Response: In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. The standard's wording regarding "spare equipment strategy" has also been revised and removed from the modeling requirements. Requirement R2.1.4 now addresses how a Transmission Planner's "spare equipment strategy" should be considered in Transmission planning. The phrase "for each year of the Transmission Planning Horizon" was deleted in the associated requirements. Requirement R1.1.2 now addresses that the models		

Organization	Question 5:	Question 5 Comments:
shall represent each year of the Near-Term and Long Term Transmission Planning Horizon. The SDT agrees with your comment on the Resource Planner. The standard is no longer applicable to the Resource Planner and the requirement has been deleted. **R1.** Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations. **R1.1** ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent: **R1.1.1** Planned outages of generation and Transmission Facilities, if specifically known. **R1.1.2** New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as Transmission Lines Generators Circuit breakers Reactive Power devices Protection System equipment Control devices New technologies **R1.1.3** Real and reactive Demand of Load **R1.1.4** Firm Transmission Service **R1.1.5** Interchange **R1.1.6** Network resources required to supply Load **R2.1.4** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.		
Lafayette Utilities	No	In Draft 2 of TPL-001, the SDT has adopted ?Planning Coordinator? as a new defined term. That term is used frequently in the new draft Reliability Standard (including in Requirements R9 - R14 but also, most notably, in Section A.4.1.1). The

Organization	Question 5:	Question 5 Comments:
System		SDT explained in its response to comments on Draft 1 that it had taken the definition of "Planning Coordinator" from the NERC Functional Model. However, the term "Planning Coordinator" is not used in the NERC Registry Criteria, nor does it appear in the NERC Glossary. Because the latter form the basis for allocating compliance responsibilities, the SDT should eliminate use of "Planning Authority" and should adopt in its stead a term that is used in the Registry Criteria (such as "Planning Authority"). With respect to the incorporation of data provided under Reliability Standards MOD-010 and MOD-012 into the studies contemplated by the revised version of TPL-001 (see Requirements R1 and R5), Lafayette urges the SDT to clarify entities? obligations with respect to the provision and use of this data, particularly with respect to Planning Coordinators/Authorities. As presently drafted, MOD-010 and MOD-012 do not apply to Planning Coordinators or Planning Authorities, and these standards also do not provide for these entities to receive MOD-010 and MOD-012 data from the entities that are subject to these two Standards. Further, to the extent that Requirements R1 and R5 require Transmission Planners to use MOD-010 and MOD-012 data, is it contemplated that Transmission Planners will obtain this data from Resource Planners and Transmission/Generation Owners in their areas, or will Transmission Planners merely be obligated to incorporate the data that they themselves provide under MOD-010 and MOD-012 into their studies? Requirement R9 directs each Distribution Provider to furnish its "Planning Coordinator" with modeling information that includes "real and reactive load forecast data" at Transmission nodes" and "the expected mix of industrial, commercial, and residential Loads." As discussed previously with respect to Requirement 2.4.1, Distribution Providers may consider the information required by R9 to be commercially sensitive such that its disclosure could have adverse competitive effects. The information specified in R9 therefore should be protected from disclosure unless the provider of the information authorizes its release or other appropriate protections are in place. Additionally, given that this requirement directs the provision of "load forecast data," it seems more appropriate that the requirement apply to "Load-Serving Entities," "Distribution Providers that serve load" or "Distribution Providers that are also Load-Serving Entities." Requirement R10 assumes that the Transmission Planner has access at all times (and, therefore, is in a position to provide within 90 days of a request) to Firm Transmission Service Data, Interchange Schedules, and resources required to serve load for each of its Balancing Authorities for each year of the transmission planning horizon. The Transmission Planner, however, may only receive such information periodically (e.g., annually or semi-annually) from its Balancing Authorities for use in the planning process. It is more likely that, at any point during the year, the Transmission Owner, Transmission Operator, or Transmission Service Provider would have access to the specified information. Requirement R10 should be expanded to include these other entities, which probably will have access to the data throughout the planning cycle. Requirement R11 does not specify whether outage information provided by a Transmission Owner must be updated (e.g., if the outage schedule changes after being provided upon request by the Planning Coordinator). The Transmission Owner's obligations with respect to providing updated information should be clearly stated. Additionally, it is not clear what the SDT means by the phrase "giving consideration to spare equipment strategy." If the intent is that Transmission Owners shall factor into their outage decisions and timing the availability of spare equipment that might affect the need for or duration of an outage, that intent should be stated in clear terms.

Response: v4 of the Functional Model which has been approved by the BOT includes the term 'Planning Coordinator'. The definition has been deleted from this

Organization	Question 5:	Question 5 Comments:

posting as it has already been implemented in another project.

In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

The standard's wording regarding "spare equipment strategy" has also been revised and removed from the modeling requirements. Requirement R2.1.4 now addresses how a Transmission Planner's "spare equipment strategy" should be considered in Transmission planning.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~-~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent:

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as

Transmission Lines

Generators

Circuit breakers

Reactive Power devices

Protection System equipment

Control devices

New technologies

R1.1.3 Real and reactive Demand of Load

R1.1.4 Firm Transmission Service

R1.1.5 Interchange

R1.1.6 Network resources required to supply Load

R2.1.4 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.

Organization	Question 5:	Question 5 Comments:
E.ON U.S. Transmission Planning	Yes and No	R1 states “Each Transmission Planner and Planning Coordinator shall maintain System models “ and R7 states “Each Transmission Planner and Planning Coordinator shall determine and identify individual and joint responsibilities” but R9-R14 requires that data flow through the Planning Coordinator. Requirements R9-R14 should allow the data to be provided to either, as appropriate for the situation.R9 ?neighboring systems? should be replaced with more descriptive terms such as Planning Coordinators of ? or Transmission Planners of ? R10 The Transmission Planner is a user of this data, just like the Planning Coordinator, and is not the source of this data. The responsibility should be placed on the “source provider” like R9 and R11-R14. R11 The requirement should be limited to planned outages and existing outages that may be long-term due to the spare equipment strategy. The contingency analysis covers all other future outages. R12 The requirement should be limited to planned outages and existing outages that may be long-term due to the spare equipment strategy. The contingency analysis covers all other future outages.

Response: In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

The SDT agrees that the wording regarding modeling of outages is confusing. In response the SDT has eliminated Requirement R11 and included a new Requirement R1.1.1 to require modeling of planned outages of generation and Transmission Facilities when they are specifically known.

The standard’s wording regarding “spare equipment strategy” has also been revised and removed from the modeling requirements. Requirement R2.1.4 now addresses how a Transmission Planner’s “spare equipment strategy” should be considered in Transmission planning.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent:

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as

Transmission Lines

Generators

Circuit breakers

Reactive Power devices

Organization	Question 5:	Question 5 Comments:

The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.		
Orlando Utiliites Commission	No	If improvements are needed to the MOD standards then those should be addressed in the MOD standards. This is beyond the scope of the TPL standards. Creating requirements that are not within the scope of a particular standard invites compliances issues and also creates an environment where it may not be possible to comply with both standards. However if you are going to retain these please consider: R7: Revising to state "Each Transmission Planner and their associated Planning Coordinator" otherwise this could be interpreted that every TP & PC has to have an agreement with every other TP and PC in existence on their joint and individual responsibilities. R8: This seems to be redundant with the FERC order 890 requirements for an Attachment K process. That process already has an audit mechanism in FERC and a reporting mechanism in the form of the clients of that process. Having NERC auditors monitor this type of process seems a distraction from their purpose of enhancing system reliability.

Response: In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 ~~The Planning Assessment shall include documentation of the technical rationale for modification of any data that was provided in Requirement R9 through R14, MOD-010, and MOD-012.~~Models for the Planning Assessment shall represent:

Organization	Question 5:	Question 5 Comments:
R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known. **R1.1.2** New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon, such as Transmission Lines Generators Circuit breakers Reactive Power devices Protection System equipment Control devices New technologies **R1.1.3** Real and reactive Demand of Load **R1.1.4** Firm Transmission Service **R1.1.5** Interchange **R1.1.6** Network resources required to supply Load Regarding the comment pertaining to Requirement R7, the SDT believes there is an inherent association between the TP and its PC and it should not be interpreted that every TP needs an agreement with every other TP and PC. Regarding the comment pertaining to Requirement R8, the SDT believes the requirement captures the intent of FERC Order 890.		
BCTC	Yes	We can live with the proposed Requirements, but expect some problems may arise with implementation. For example, to accurately model our system for stability studies, we require models of adjacent systems. It is not clear how we will coordinate this requirement within the WECC base case process.
PacifiCorp	Yes	We agree that the MOD Standards need modifications and additions to be used for Transmission Planning, We also agree with the movement of the R1of the first draft to the R9 through R14 of this draft, We also agree that when the MOD Standards are replaced, then remove these Requirements from the TPL Standard.
Arizona Public Service Co.	Yes	We agree that the MOD Standards need modifications and additions to be used for Transmission Planning, We also agree with the movement of the R1of the first draft to the R9 through R14 of this draft, We also agree that when the MOD Standards are replaced, then remove these Requirements from the TPL Standard.

Response: Thank you for your response but the majority of the industry has responded negatively and the SDT has changed the requirements as shown in the summary response. .		

6. The SDT has modified the requirements relating to short circuit analysis   Do you concur with the modifications reflected in Requirements R2.3 and R4. If not, please state why and/or suggest specific changes.

Summary Consideration:

The majority of commenters responded negatively. In general, commenters indicated a need for clarifying what specific short-circuit studies were required. While it's an annual requirement, what year or years should be studied? Is there both a short-term and long-term requirement or is it just short-term? In addition, the need for studies beyond those of a "normal system" was also questioned. To provide clarity on these issues, the SDT changed Requirements R2.3 and R2.6.2 and created a new Requirement, R2.7, to address the need for corrective actions specific to when fault interrupting duties are exceeded while also deleting Requirement R4 as those requirements are now included in Requirement R2.3. In addition, some entities suggested these requirements belong in a separate standard such as FAC-002 or a new standard. However, the SAR for this project specified that short-circuit requirements would be included in TPL-001; therefore, the suggestion to move these short-circuit study requirements to a separate standard cannot be implemented. Also, the need for, or applicability, of 'single Contingencies' in Requirement R4 was dropped when Requirement R4 was merged into Requirement R2.3.

In response to industry comments, Requirement R4 has been deleted and the following requirements have been changed:

R2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.

R2.6.2 (now R2.5.2) For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

- The addition/deletion/change of individual generating unit capability of 20 MW or greater.
- An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES which total 20 MW or greater.

R2.7 For short circuit analysis, if the short circuit current interruption duty on fault interrupting devices determined in Requirement R2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

R2.7.1 List System deficiencies and the associated actions needed to achieve required System performance.

R2.7.2 Be reviewed in subsequent annual Planning Assessments as to implementation status.

Organization	Question 6:	Question 6 Comments:
NPCC	No	In R4, suggest striking, "that would result in greater circuit breaker interrupting duties?".
Los Angeles Department of Water and Power	No	Short circuit study is a static study, there is no dynamic involved. The main purpose of short circuit study, from a planning perspective, is to size the breakers to ensure the breakers can interrupt a fault in the system when called upon. R4 requires simulation including contingencies, for what purpose is not known. The language implies there are single contingencies that could result in higher duties. I disagree. The highest duty a circuit breaker will see is when the system is whole and with all generator units in service and the fault to be cleared is a bus fault. Any single contingency that involve losing a unit or any component in the system will result in a weaker system and less short circuit duties. This is elementary. I cannot envision of any single contingency that would put more units on line or switch in additional transmission facilities beyond a full system with all unit already in service. In R2.3, the requirement is to do the study on an annual basis "and" support of past studies. If the intent is to allow past studies to substitute for annual study, the word "and" should be changed to "or". If the intent is to mandate annual study, then the support of past studies is irrelevant since the annual study supersedes past ones. In addition, short circuit study does not need to be performed annually unless there is substantive addition to the system in the form of a generating unit or a major transmission facility. So it make sense to allow past studies in lieu of annual study if there is no substantive addition to the system.
Transmission Agency of Northern California	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
OPUC	Yes and No	What constitutes a ?normal condition? still needs further clarity.
Pacific Gas and Electric Co.	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Public Service Company of New Mexico	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion

Organization	Question 6:	Question 6 Comments:
		whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
PacifiCorp	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal condition and following any single Contingency condition that would result in greater circuit breaker interrupting duties”. Since short circuit studies are typically performed by applying a three phase fault on a Facility starting from a normal condition, please clarify whether the result would constitute ?normal? condition or ?following any single Contingency condition?.
Puget Sound Energy, Inc.	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties”. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Idaho Power Company	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal condition and following any single Contingency condition that would result in greater circuit breaker interrupting duties”. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or ?following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
SMUD	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Hydro-Quebec TransEnergie (HQT)	No	In R4, suggest striking, "that would result in greater circuit breaker interrupting duties?".
Sierra Pacific Power Comapny	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal condition and following any single Contingency condition that would result in greater circuit breaker interrupting duties”. Since short circuit

Organization	Question 6:	Question 6 Comments:
/ Nevada Power Company		studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Black Hills Corporation	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Arizona Public Service Co.	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal condition and following any single Contingency condition that would result in greater circuit breaker interrupting duties”. Since short circuit studies are typically performed by applying a three phase fault on a Facility starting from a normal condition, please clarify whether the result would constitute “normal” condition or “following any single Contingency condition”.
Exelon Transmission Planning	No	R2.3 is not clear as to which year’s studies are required. Is the Planning Assessment time frames in R2 also applicable to R4? The phrase 'years one or two of the near-term planning horizon' should be included.
SRP	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Tucson Electric Power Company	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.

Organization	Question 6:	Question 6 Comments:
SERC Dynamics Review Subcommittee	Yes	It is not clear in the standard what is meant by ?single contingency?? Is the concern in Requirement R4 limited to single contingencies that may result in a system state which results in a greater circuit breaker interrupting duty?
Austin Energy	Yes and No	Transmission Planners should assess equipment short-circuit capability under normal conditions, but the need assess its capability following a contingency is so rare it should be left to the planner's selective analysis and not made a specific requirement in the standards.
Modesto Irrigation District	Yes and No	Comments: We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting there reference to the contingencies to be used in the study.
Tri-State Generatino and Transmission Association, Inc.	Yes and No	R2.3 is acceptable as written. R4 is redundant and should be eliminated. Also, the contingency short circuit study requirement does not appear to meet the purpose described in this draft standard (breaker duty monitoring). Three-phase short circuits on an intact system should cover the highest fault conditions, and thus the most critical breaker duty conditions.
Tri-State G&T	Yes and No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition.” Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Lakeland Electric	No	R2.3 or R4 should specify how many and / or how to choose which years of the planning horizon shall be studied. R4 should specify method of choosing which single contingencies to study as larger systems will require an inordinate amount of work to outage every element during each of the study years of the short circuit analysis.
Brazos Electric Power Cooperative, Inc.	No	2.3 is acceptable, the deletion was recommended in our previous comments.R4 should not be added to this Standard. It adds nothing to the document the way it is worded and is quite similar to 2.3.

Organization	Question 6:	Question 6 Comments:
NERC and Regional Coordination	No	Attributes of the short circuit analysis needs to be better define. For example which studies need to be done, for what period and how often.
ColumbiaGrid	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal condition and following any single Contingency condition that would result in greater circuit breaker interrupting duties”. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study. We suggest R4 be modified to read “Short circuit capability of its equipment under plausible system configurations that would result in the greatest circuit breaker interrupting duties”.
Midwest ISO	No	The language throughout the standard is not precise as relates to "studies", "analysis", and "assessments". R2.3 appears to say that the actual simulations upon which the annual assessments are made need not be a current year study. If that is the intent the following wording would be more clear: "Short-circuit assessments shall be conducted annually and may be supported by current or past studies. R4 should be grouped with R2.4. In general the standard seems to meander and elements of the same types of studies are scattered, making it difficult to grasp the study requirements with clarity. Also the language of R4 is unclear as it describes short circuit studies in terms of contingencies. Better language would be "shall assess the short-circuit capability of its equipment under system intact topology and any single facility (or branch) out condition that is expected to result in greater ?".
Southern California Edison	Yes and No	We agree with R2.3. However, R4 requires assessment of “Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute “normal” condition or “following any single Contingency condition”. Also, by specifying the normal and single contingency conditions, R4 is straying into “how” to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Northeast Utilities	No	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.
Duke Energy	No	It is not clear in R4 what is meant by ?single contingency? and this situation is unlikely to increase fault current. The phrase ?under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting

Organization	Question 6:	Question 6 Comments:
		duties? should be deleted.
Central Maine Power Company	No	a. R2.3 should be changed to indicate the year(s) for short circuit analysis. b. In R4, suggest replacing, " and following any single Contingency condition that would result in greater circuit breaker interrupting duties" with, " giving due consideration to the potential sequence of equipment operation". c. It should be stated in the standard that assumptions should be based on procedures provided by each Transmission Planner and by the Planning Coordinator.
NSTAR Electric	No	1. R2.3 should be changed to indicate the year(s) for short circuit analysis. 2. In R4, suggest replacing, " and following any single Contingency condition that would result in greater circuit breaker interrupting duties" with , " giving due consideration to the potential sequence of equipment operation". 3. It should be stated in the standard that assumptions should be based on procedures provided by each Transmission Planner and by the Planning Coordinator.
New York Independent System Operator	No	In R4, suggest striking, "that would result in greater circuit breaker interrupting duties?".
Alberta Electric System Operator	No	We agree with R2.3. However, R4 requires assessment of ?Short-circuit capability of its equipment under normal conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties?. Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
ISO New England Inc.	No	a. R2.3 should be changed to indicate the year(s) for short circuit analysis. b. In R4, suggest replacing, " and following any single Contingency condition that would result in greater circuit breaker interrupting duties" with , " giving due consideration to the potential sequence of equipment operation". c. It should be stated in the standard that assumptions should be based on procedures provided by each Transmission Planner and by the Planning Coordinator.
US Bureau of	No	Comments: We agree with R2.3. However, R4 requires assessment of “Short circuit capability of its equipment under normal

Organization	Question 6:	Question 6 Comments:
Reclamation		conditions and following any single Contingency condition that would result in greater circuit breaker interrupting duties". Comment Form for 2nd Draft of Standard TPL-001-1Assess Transmission Future Needs (Project 2006-02)Page 7 of 12Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute ?normal? condition or ?following any single Contingency condition?. Also, by specifying the normal and single contingency conditions, R4 is straying into ?how? to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
BPA Transmission Reliability Program	Yes and No	We agree with R2.3. However, we recommend removing the reference to single contingency conditions in R4, for the same reasons as described in the WECC comments. See below: "Since short circuit studies are typically performed by applying a fault on a Facility starting from a normal condition, there can be confusion whether the result would constitute "normal" condition or "following any single Contingency condition". Also, by specifying the normal and single contingency conditions, R4 is straying into "how" to perform a study, which is not necessary in a standard. We suggest deleting the reference to the contingencies to be used in the study.
Response: Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. Also, the need for, or applicability, of 'single Contingencies' in Requirement R4 was dropped when Requirement R4 was merged into Requirement R2.3. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
City Water, Light & Power - Springfield, Illinois	Yes and No	For R2.4 stability studies should not be required annually but should only be required if there is a significant change to the system or system stability was marginal as shown in previous studies.
Response: This question is related to short circuit, Requirement R2.3, not Requirement R2.4, Stability. However, if past studies are applicable, it is not necessary to rerun Stability studies more often than once every 5 years. Your examples are good examples of when a Stability study may need to be rerun more often than once every 5 years.		
BCTC	Yes	R.3 and R4 are acceptable, although we note the R4 gets into details of how to do short circuit analysis which is unnecessary for this standard. In some cases it may be necessary to consider multiple contingencies. Should R2.6.2 say "the SYSTEM shall not include material changes?"?
Response: Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can		

Organization	Question 6:	Question 6 Comments:
be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area. The SDT has changed Requirement R2.6.2 (now R2.5.2) to provide clarification. **R2.5.2** For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:		
Manitoba Hydro	No	R4: The wording for the assessment should be changed from "shall assess the short circuit ability of its equipment" to "shall assess whether bus short circuit levels are within the capability of its equipment". The short circuit assessment should only be required if changes to system topology or generation occur. While short circuit levels are critical for system equipment specifications, ten year planning horizon models are generally not adequate for this purpose as ultimate system fault levels are required. The SDT should clarify the modelling details required for the short circuit assessment and the deliverable of the short circuit assessment. The standard doesn't stipulate if an existing NERC model will need to be modified to include the sequence data and thus allow for three phase and SLG fault analysis or if the planner is to use our "in house" models and just report the results. Typically, short circuit models used for fault studies are not load or season specific, and the simulation is conducted using a flat-analysis (load ignored and voltage at 1.0 pu). Typically, all elements are in service to ensure maximum fault contribution. Can the SDT provide details on what cases have to be assessed ? Year One, each of the first five year, etc. What is the generation dispatch that should be considered? For purposes of equipment rating, a dispatch considering all available generation may need to be considered. Manitoba Hydro requests the SDT to provide some specifics on the need for doing intact and n-1 fault analysis. We think the requirement to consider single contingency conditions is getting into the details of bus modeling to maximize the fault level. If so this seems to be getting into short circuit study methodology and is too prescriptive and unnecessary. To explain this comment, we include a summary of the process used at Manitoba Hydro as follows: Manitoba Hydro follows a two step procedure when studying breaker capability of our system:1. Breaker Rating vs. Bus Fault - Breakers are required to accommodate the entire bus maximum symmetrical fault current at nominal bus voltage with no consideration given to what the circuit breaker may actually be required to interrupt due to its location in the ring. Stations with fault levels above 95% of rated breaker interrupting capability are flagged for further study. This type of analysis will accurately rule out a high percentage of breakers whose capability is adequate. If an appropriate model is available, this step could take up to three person-months for the Manitoba Hydro system. 2. Detailed Examination of Breaker Duty and Location - By considering faults on both the equipment and bus side of the breaker the exact fault current that the breaker must interrupt can be determined. In a ring bus arrangement the breaker in question is assumed the last breaker to clear the fault. In addition, factors such as X/R ratio & operating voltage are also taken into account. To provide a safety margin to account for modeling tolerances we recommend a circuit breaker for replacement when the fault value is greater then 95% of the breaker rating. Other companies may use different breaker replacement threshold levels. This detailed analysis could require up to one person-month, depending on the size of the station, for each detailed assessment. The standard should specify what is to be reported as a result of the short circuit study. Should the report include:? Documentation of the criteria used for the study? A

Organization	Question 6:	Question 6 Comments:
		listing of the SLG and three phase fault levels compared to the lowest breaker capability at a bus. ? Documentation of more detailed analysis of for breakers whose capability is within threshold of the station fault level.? A listing of the breakers to be replaced. Alternatively, should the standard just require the planner have a separate report on the fault analysis that can be provided on request.

Response: Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model.

R2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.

The SDT has chosen not to prescribe all conditions but expects that studies would assume all equipment in service, which could impact the study area, to calculate maximum potential fault currents.

Organization	Question 6:	Question 6 Comments:
National Grid	No	a. R2.3 should be changed to indicate the year(s) for short circuit analysis. b. In R4, suggest replacing, " and following any single Contingency condition that would result in greater circuit breaker interrupting duties" with , " giving due consideration to the potential sequence of equipment operation". c. It should be stated in the standard that assumptions should be based on procedures provided by each Transmission Planner and by the Planning Coordinator.

Response: (a) & (b): Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. Also, the need for, or applicability, of 'single Contingencies' in Requirement R4 was dropped when Requirement R4 was merged into Requirement R2.3.

R2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.

(c) Procedures used to meet short-circuit requirements of Requirement R2.3 should be included in Requirement R2.7.1 mandated Corrective Action Plans.

Organization	Question 6:	Question 6 Comments:
Gainesville Regional Utilities	Yes and No	With a small system like ours, I would like to see a provision where if you do not have any changes in our local portion of the BES, then the previous studies would support my assessment.

Response: This is addressed in the revised Requirement R2.6.2 (now R2.5.2).

R2.5.2 For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

Organization	Question 6:	Question 6 Comments:
The addition/deletion/change of individual generating unit capability of 20 MW or greater. An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES which total 20 MW or greater.		
JEA	Yes and No	JEA can agree to this requirement; however, JEA would like to see it addressed in FAC-002 to maintain consistency with the FAC standard requirements.
Response: FAC-002 references the TPL standards to ensure that a short-circuit study is run for new Facilities. The SDT believes that the consistency will continue to exist. The SAR for TPL-001-1 specified that short-circuit studies were to be included in the requirements.		
Progress Energy Florida, Inc.	No	PEF disagrees with, and recommends removal of both R2.3 and R4 on the following grounds:R2.3: Evidence that short circuit analysis has been performed is already mandated through Requirement R1.4 NERC Standard FAC-002-0. Inclusion of the mandate in the TPL Standard is redundant.R4: While the fundamental inadequacy of the short circuit issue is its inclusion in the TPL Standard to begin with (see R2.3 comments), PEF is perplexed at the proposed requirement to perform short circuit analysis for single contingencies. PEF cannot conceive of a scenario for which a single contingency scenario would result in increased fault duty. Such a mindset essentially considers short circuit analysis as equivalent to load flow analysis, which it clearly is not. Short circuit analysis is performed to adequately set relays, size equipment and prevent equipment damage, and as such is not appropriate for inclusion in a TPL Standard.
Florida Power and Light	No	R4. Why is short circuit analysis required for single contingencies? Removing equipment through contingency outages lowers available short circuit duty. Short circuit analysis is not a parallel version of load flow analysis. Evidence that short circuit studies have been performed is currently required in the existing FAC-002-0 Standard. Since the primary concern is the appropriate sizing of equipment and the prevention of equipment damage as opposed to overall grid reliability, we do not see the need for a set of requirements within the proposed TPL standard for short circuit studies.
Florida Reliability Coordinating Council, inc	No	Recommend for the removal of both R2.3 and R2.4. Short Circuit analysis should be addressed in FAC-002 by revising the standard to include additional detail within FAC-002. Another option would be to develop a new standard addressing short circuit studies and requirements.
Response: FAC-002 requires coordination for new Facilities but points back to the TPL standards for requirements that must be coordinated. The SDT believes short-circuit requirements belong in TPL-001-1 and the SAR for TPL-001-1 specified that short-circuit studies were to be included in requirements. Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System		

Organization	Question 6:	Question 6 Comments:
short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
Lafayette Utilities System	No	Lafayette has identified two issues with respect to the Short Circuit Analysis required in TPL-001. First, Requirements R2.3 and R4 do not describe the required Short Circuit Analyses in sufficient detail to ensure that these studies are performed using topology assumptions that are consistent with the assumptions used in the Steady-State and Stability Studies. If inconsistent topology assumptions are used, the results of the analyses would not present a clear and consistent picture for planning purposes. Second, interconnection studies performed under the FERC LGIP procedures typically include considerable short-circuit analysis of the interconnecting transmission system. Entities required to perform an annual Planning Assessment should be permitted to use, for TPL-001 compliance purposes, any up-to-date short-circuit analyses that may have been conducted for an LGIP interconnection study. Forcing these entities to re-perform the analyses for TPL-001 compliance would impose unnecessary cost.
Response: Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area. Please note that this requirement allows for the utilization of past studies.		
Ameren	No	Requirement R4 should be modified to remove the Planning Coordinator such that the "Transmission Planner shall assess the short-circuit capability of its equipment considering maximum interrupting duty for normal or single element outage conditions".
Response: The Planning Coordinator is the appropriate entity in some areas. In those areas where this is not the case, the Planning Coordinator may defer to the Transmission Planner's studies. This is a joint responsibility between the Transmission Planner and Planning Coordinator.		
CenterPoint Energy and CPS Energy	No	We believe R4 is unnecessary and, judging from industry comments to the previous draft, likely to cause confusion among auditors and planners alike. Furthermore, we believe R4 does not address an actual problem. We are not aware of situations where equipment has been under-rated from the standpoint of short circuit ratings. We recommend that R4 be deleted.
Response: The SDT does not believe that the concepts of Requirement R4 should be eliminated as without them, there would be a requirement for short-circuit studies with no specific result expected. However, Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System		

Organization	Question 6:	Question 6 Comments:
short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
MidAmerican Energy Company	No	a. Since the TPL contingency requirements already require bus fault, stuck breaker, and breaker failure contingencies, MEC asks the SDT to clarify the purpose of the short circuit study requirements. The benefit to additional short-circuit studies is minimal since analyses already ensure that the system can withstand bus faults and breaker failures. b. The SDT should clarify what single contingencies are to be studied for short circuit studies in R2.4. Is it single contingency as defined in Table 1? Or is it a broader or narrower definition? MEC recommends that since this is a new requirement, that TPL-001-1 be limited to raise the bar only to involve the single contingencies identified in P1. Failure to do so will require a great deal of additional modeling work in short-circuit studies if single contingencies in P2 are to be included in these studies with minimal benefit.
Response: (a) These requirements apply to steady state (load flow) and Stability analysis but they do not specifically address short-circuit requirements. The performance requirements in Requirement R2.3 are specific to short-circuit studies. (b) Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. Also, the need for, or applicability, of 'single Contingencies' in Requirement R4 was dropped when Requirement R4 was merged into Requirement R2.3. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
MRO NERC Standards Review Subcommittee	No	a. Since the TPL contingency requirements already require bus fault, stuck breaker, and breaker failure contingencies, the MRO asks the SDT to clarify the purpose of the short circuit study requirements. The benefit to additional short-circuit studies is minimal since analyses already ensure that the system can withstand bus faults and breaker failures. b. The SDT should clarify what single contingencies are to be studied for short circuit studies in R2.4. Is it single contingency as defined in Table 1? Or is it a broader or narrower definition? The MRO recommends that since this is a new requirement, that TPL-001-1 be limited to raise the bar only to involve the single contingencies identified in P1. Failure to do so will require a great deal of additional modeling work in short-circuit studies if single contingencies in P2 are to be included in these studies with minimal benefit. c. The MRO suggests added clarification of the following questions: 1. Should analysis be performed for the near-term and long-term planning horizon? 2. Should only the peak system condition be analyzed? 3. What does the analysis include (e.g. breaker over duty evaluation and protective relay coordination)? R4 - Clarify that the "short-circuit capability of its equipment under normal conditions" (P0) refers to interruptible rating for breakers only.
Response: (a) These requirements apply to steady state (load flow) and Stability analysis but they do not specifically address short-circuit requirements. The		

Organization	Question 6:	Question 6 Comments:
performance requirements in Requirement R2.3 are specific to short-circuit studies. (b) Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. Also, the need for, or applicability, of 'single Contingencies' in Requirement R4 was dropped when Requirement R4 was merged into Requirement R2.3. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area. (c) The SDT believes that the concerns raised here are covered in the revised requirement R2.3.		
Arkansas Electric Coop. Corp.	No	R2.3.1 should not be deleted. While system wide short circuit analysis should be done annually, there are situations where changes in the BES do impact the short circuit. If these changes result in new equipment needing to be ordered then this needs to be know as soon as possible in order to prevent exceeding equipment ratings or delays because of lead times on equipment.
Response: Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area. The SDT has added Requirement R2.7 to provide a Corrective Action Plan. **R2.7** For short circuit analysis, if the short circuit current interruption duty on fault interrupting devices determined in Requirement R2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall: **R2.7.1** List System deficiencies and the associated actions needed to achieve required System performance. **R2.7.2** Be reviewed in subsequent annual Planning Assessments as to implementation status.		
ERCOT System Planning	No	ERCOT believes R4 is unnecessary and does not address an actual problem; ERCOT recommends that R4 be deleted. ERCOT does not presently possess the capability or have access to the data needed to perform the calculations required by R4 as this requirement should apply to only the equipment owner (GO or TO).
Response: The Planning Coordinator is the appropriate entity in some areas. In those areas where this is not the case, the Planning Coordinator may defer to the Transmission Planner's studies. This is a joint responsibility between the Transmission Planner and Planning Coordinator. Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can		

Organization	Question 6:	Question 6 Comments:
be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
American Transmission Company	No	We suggest added clarification of the following questions: 1. Should analysis be performed for the near-term and long-term planning horizon? 2. Should only the peak system condition be analyzed? 3. What does the analysis include (e.g. breaker over duty evaluation and protective relay coordination)? 4. Does the analysis of single contingency for greater duties refer to only the P1 category or both the P1 and P2 categories?R4 - Does the equipment capability reference include the ground grid and bus structures?
Response: The SDT did not add references to equipment beyond interrupting equipment. Circuit breaker or interrupting device ratings should already include support equipment. Lines are rated by the most limiting element and interrupting equipment ratings should also be rated by the most limiting equipment. Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
FirstEnergy Corp.	No	We do not feel that it is necessary to annually update the short circuit analysis. We suggest the SDT consider increasing this timeframe. In addition, short circuit analysis should be reviewed in areas where transmission or generation changes are planned. Lastly, we feel it would be beneficial for the standard to provide examples of contingencies that could increase fault duties.
Response: An annual "assessment" must be made, but this doesn't necessarily mean a new study unless topology changes accordingly. The SDT has revised Requirement R2.6.2 (now R2.5.2) which allows for the use of past studies. **R2.5.2** For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability of 20 MW or greater. An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES which total 20 MW or greater. Requirement R4 has been deleted and those requirements have been merged into Requirement R2.3 to reflect the expected short circuit model. **R2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies. The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System		

Organization	Question 6:	Question 6 Comments:
short circuit model with any generation and Transmission Facilities in service which could impact the study area.		
Orlando Utiliites Commission	Yes and No	OUC agrees with other commentors that if there is a need for monitoring this, it should perhaps be in a different standard.
Response: The SAR for TPL-001-1 specified that short-circuit studies were to be included in the requirements.

7. The SDT has reformatted the Steady State and Stability Performance Tables. Do you concur with the modified format? If not, please state why and/or suggest specific changes.

Summary Consideration:

In responding to the reformatted performance tables, industry stakeholders had several comments related to the format changes and also took an opportunity to provide feedback on the table content as well. A summary of the more common industry responses is provided below along with the SDT's reply to each.

FORMAT COMMENTS:

1. The most common input received from industry related to the format of the tables was a desire for the SDT to consider a single table design covering both steady-state and stability. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table design.

2. Many commenters felt the two table design was unduly long covering 13 pages compared to the two (2) pages used for the existing FERC approved TPL standards. Based on the redesigned single format table, the SDT has condensed the information to only 3 pages in the proposed Draft 3 version.

3. Another format change requested was to repeat the header row of column headings on each page. The SDT agrees and has made this change.

4. A few commenters correctly pointed out confusion between the introductory notes and the footnotes which both used numeric references. The SDT corrected this problem by using alpha character references for the introductory notes. The references within the table now clearly point to the footnotes and follow a more logical numerical order.

5. Several stakeholders suggested a Planning Event category naming convention for Planning Steady-State as (P1, P2, P3, …) and Stability as (S1, S2, S3, …) for the two table design. The SDT did not make this change based on a redesign to a single performance table. The team has retained the P1 through P7 references for Planning Events.

CONTENT COMMENTS:

1. The SDT agrees with a number of stakeholders that expressed an opinion on the need to allow for all types of conditional Firm Transmission Service Interruptions, not just those limited to HVDC. The SDT recognizes that the prior Draft 2 version unintentionally provided preferential treatment to HVDC. In the new performance Table 1, a new footnote has been added (see footnote 5) to the column title "Interruption of Firm Transmission Service Allowed" that corrects the problem identified.

2. Some commenters questioned the distinction in performance requirements for the above 300 kV systems. The SDT believes the Draft 2 changes are responsive to the prior industry feedback and reflect an appropriate middle ground related to the importance of the EHV Transmission System. The team has now included a slightly modified version of stated performance requirements in Draft 3. The SDT has clarified that interruption of Firm Transmission Service is warranted for some Contingencies. The SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm Transmission service is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained.

3. A number of commenters expressed concern related to Planning Event P5 "Protection System Failure" and the need to evaluate a single component failure of a BES Protection System; particularly a failure of a station battery. The SDT has revised the P5 Planning Event description to remove the reference to "single component failure" and the event description was changed to match what is stated in the currently approved TPL standards under Category C6 through C9. The intent of P5 is to evaluate a failure of a single Protection System design that introduces a delayed clearing mode that may also include additional electrical Facilities being removed when compared to normal fault clearing. A Protection System failure resulting in loss of the substation (one voltage level plus transformers) would not qualify as a P5 Planning Event since that event is considered an Extreme Event. A Standard Authorization Request (SAR) has been issued for industry comment (1/20/2009 through 2/18/2009) based on work completed by the System Protection and Controls Task Force (SPCTF). The proposed project will address the need for Protection System redundancy, based on an n-1 failure of individual components of the Protection System.

4. Some commenters were confused by Planning Event P2.1 and the SDT has added footnote 8 to better clarify the intent of the P2.1 Contingency review.

5. Many stakeholders correctly noted that Extreme Event item 1 excluded the reference to shunt device. This has been corrected and now includes shunt devices.

6. Some commenters questioned the order of the Planning Events and questioned if they were based on a high to low probability order. The SDT chose to order the table by three main areas: 1) no Contingency (P0), 2) single Contingency

(P1 and P2), and multiple Contingency (P3 through P7). While the SDT agrees there is some overlap in probability order, for example, between P2 and P3, the SDT has more importantly made the proper performance level requirements based on a reliability "risk" level where risk accounts for impact times (x) probability of occurrence.

7. Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these system designs are permissible under the presently approved TPL-002-0 standard. FERC, in Order 693, was clear in paragraph 1794 that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement. As an alternative, an entity could seek an entity variance for the situation described through their Regional Entity organization. In paragraph 1794, FERC clarified that "…an entity may seek a regional difference to the Reliability Standard from the ERO for case-specific circumstances". The process described by FERC as a regional difference is described in detail in the "NERC Standards Development Procedure" document under the subsection titled "Variances to NERC Reliability Standards".

The following changes have been made to the standard based on industry comments:

Requirements:

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

R2.9 ~~The Planning Assessment shall identify the maximum permissible Non-Consequential Load Loss (megawatt Demand) for those Planning Events where Non-Consequential Load Loss is allowed in Table 1.~~

Table 1 Header Notes

e. For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

h. Planning Event P0 is applicable to steady state only.

Table 1 - Extreme Events – Steady State:

1. Loss of a single generator, Transmission Circuit, DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, DC Line, shunt device, or transformer forced out of service prior to System adjustments.

3b. ~~Loss of two Transmission lines in different rights-of-way prior to System adjustments for conditions such as:~~

Table 1 Footnotes:

2. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level for stated performance criteria applies regarding allowances for interruptions of Firm Transmission Service and loss of Non-Consequential Load.

3. Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø fault study indicating criteria are being met shall provide sufficient evidence that a SLG condition would also meet criteria.

5. When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

7. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground.

8. Inadvertent tripping of breakers on one end of a normally networked Transmission circuit such that the line is now open at that end and possibly serving Load radial from a single source point.

10. Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

11. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) breaker, only one pole is assumed to remain closed. ~~The~~A stuck breaker ~~event~~ introduces a delayed clearing mode. ~~Normal Clearing is when the Protection System operates as designed and the Fault is cleared in the time normally expected with proper functioning of the installed protection systems. Breaker fail relay operation is a predetermined time that occurs after the Protection System operates and the breaker has failed. Breaker fail relaying will also isolate a predetermined portion of the electric system to isolate the failed breaker. Delayed clearing of a Fault is due to failure of any Protection System component that prevents the Protection System from operating normally.~~

Organization	Question 7:	Question 7 Comments:
Dominion - Electric Transmission Planning	Yes and No	(1) Dominion - Electric Transmission is okay with the format changes, but suggests that consideration be given to changing the category naming convention for Stability Performance Table 2 to S1, S2, etc. rather than P1, P2, etc. for clarity and to distinguish them from Steady State Performance Table 1.(2) The tables could be improved if the headings were put on each separate page.

Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". This change has negated the need for the Planning

Organization	Question 7:	Question 7 Comments:
Event category naming convention changes suggested by the commenter and the SDT retained the P1 through P7 references for Planning Events. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.		
NPCC	No	In both Table 1 and Table 2, the "Interruption of Firm Transmission Service Allowed" column. It is problematic to try to create an "exemption" based on type of facility such as HVDC. There are many other situations in which Firm Transmission Service has been provided, but may need to be curtailed partially or completely following an outage. It is recommended that a note be added stating that the only exception would be for curtailment of conditioned (or Conditional) Firm Transmission Service, recognizing that there may need to be some form of grandfathering in order to avoid having to rewrite transmission service agreements. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." In Table 1, the "Extreme Event Descriptions" item 3b should be deleted; it is redundant with Item 1. In Table 2, Note 5 includes significant clarifications and should not be buried in the bottom of the contingency table; Note 5 would be better placed in the definitions section. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure, such as a battery system, which may remove ALL protection at some substations. This Contingency P5 requires all voltages and loadings to remain within criteria, and a stable system response; without interruption of firm transmission service and without Non-Consequential Load Loss, at voltages above 300 kV. Was this an intended outcome of this standard?
Northeast Utilities	No	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.
Response: The SDT team agrees with the commenter's opinion on the need to allow for all types of conditional Firm Transmission Service Interruptions and that the prior Draft 2 version unintentionally provided preferential treatment to HVDC. In the new performance Table 1, a new footnote has been added (see footnote 5) to the column title "Interruption of Firm Transmission Service Allowed" that corrects the problem identified by the commenter. **5**. When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. The SDT agrees that shunt devices were excluded in Extreme Event item 1 of the Steady-State and Stability tables and the problem has been corrected. The SDT agrees with the commenter regarding the opinion that item 3B in the Extreme Event portion of the prior Daft 2 Table 1 Steady-State was redundant and the item has been removed and is no longer referenced in this draft. **Extreme Events - 3b**. ~~Loss of two Transmission lines in different rights-of-way prior to System adjustments for conditions such as:~~ The SDT appreciates the input related to the footnote on "System Stable" (new footnote 1). The SDT has chosen to leave the information within a footnote and		

Organization	Question 7:	Question 7 Comments:
did not include it as a new definition for the NERC Glossary of Terms as suggested by the commenter. Related to the P5 “Protection System Failure” Planning Event the SDT has not deviated from its stance of requiring more stringent performance requirements for the above 300 kV System. The SDT has revised the P5 Planning Event description to remove the reference to “single component failure” and the event description was changed to match what is stated in the currently approved TPL standards under Category C6 through C9. The intent of P5 is to evaluate a failure of a single Protection System design that introduces a delayed clearing mode that may also include additional electrical Facilities being removed when compared to the normal fault clearing. A Protection System failure resulting in loss of the substation (one voltage level plus transformers) would not qualify as a P5 Planning Event since that event is considered an Extreme Event. A Standard Authorization Request (SAR) has been issued for industry comment (1/20/2009 through 2/18/2009) based on work completed by the System Protection and Controls Task Force (SPCTF). The proposed project will address the need for Protection System redundancy, based on an n-1 failure of individual components of the Protection System.		
TVA System Planning	Yes	TVA believes that the new table format does make the tables much easier to follow. However, the tables can be a little hard to follow for those categories that have both over and under 300-kV categories. Also having header pages at the top of each page of the tables would also help. Should P6 and P7 events be moved to Extreme Events since firm transmission and non-consequential load can be dropped for these events? Seems like these events are very similar to the Extreme Events.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The SDT has elected to retain both P6 (N-1-1) and P7 (Common Tower N-2) Planning Events in this third draft. There was no compelling industry opinion for the change and the events were considered by the SDT to be credible events and warrant the Planning Event level of scrutiny. There are more severe versions of these events contained with the Extreme Event area.		
City Water, Light & Power - Springfield, Illinois	Yes and No	Place the titles on each page and put the borders back in.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The SDT believes the new table will also address your concern regarding the borders. If not, please provide a more specific comment in your review of the Draft		

Organization	Question 7:	Question 7 Comments:
3 standard.		
Progress Energy Carolinas	Yes	The readability of the tables could be improved if the headings were put on each separate page. Separating out the tables for steady state and stability greatly improves and clarifies the requirements of the standard. Additionally, we would prefer that dynamic planning events use labeling such as D1, D2, etc. instead of P1, P2, etc. to differentiate them from steady state events.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The move to a single table has negated the need for the Planning Event category naming convention changes suggested by the commenter and the team retained the P1 through P7 references for Planning Events. The move to a single table was based on a significant number of comments and based on the SDT’s view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.		
Platte River Power Authority	Yes and No	I like the emphasis on stability performance but I prefer one table combining steady-state and stability Categories since the Planning Events are common to both. Divide notes, Evaluation Requirements, and Extreme Events Descriptions into two sub-tables.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The move to a single table was based on a significant number of commenters, like yourself, who felt a single table would suffice. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The SDT divided the top notes between those that are applicable to Steady-state, Stability or both as suggested by the commenter.		
BCTC	No	The differences in the tables requiring two tables are not apparent. Furthermore, we have become familiar with working with the current Table 1. Changing to these new tables will result in transition costs. We see no problems with continuing to use the current Table 1 and would prefer to retain it.
Response: While the new tables and naming conventions will require some effort for industry adaption, the SDT believes the tables provide greater clarity and drive the reliability improvements desired by FERC Order 693.		

Organization	Question 7:	Question 7 Comments:
Manitoba Hydro	No	There appears to be little difference between Table I and II other than the performance requirements at the start of each table, which should be embedded within standard. Manitoba Hydro would prefer one table as we believe it serves to simplify the standard readability. Additional Comments on Table 1:The Performance Requirements (Items 1 to 6) should have a heading "Evaluation Requirements". These evaluation requirements should be included in the standard body. Also they should be labeled A to F to avoid confusion with the Notes at the end of the Table. Item 6 is not applicable for steady state analysis. Suggest changing "Notes" to "Table I Notes" for improved readability if more than one table is retained. Planning Events: In cases where Non-consequential Load Loss is allowed, has the SDT discussed limiting the amount of load lost? Planning Events: For the multiple contingency events, in cases where Interruption of Firm Transmission Service or Non-Consequential Load Loss is allowed, the SDT should clarify that such loss is only allowed after the second event. P1: Similar to DC lines, interruption of Firm Transmission Service should be allowed for AC transmission lines, as in many cases, the firm transmission service is dependent on the outaged AC transmission line or transformer, that is, the contract path. P2-1: Suggest changing :single ended line: to "open ended line". P3: Similar to DC lines, interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer - the contract path. Planning Events >300 kV: Interruption of firm transfer should be allowed if AC contract path is lost due to an event. In many cases the majority of the firm transfer is carried by the contract path ac line, not that unlike the case of the DC line. MH has sold Firm Transmission Service, the delivery of which is dependent on the single circuit Winnipeg-Twin Cities 500 kV line being in-service, This Firm Transmission Service is available in the order of 99.6% of the time. Assuming two 5 day planned maintenance outages per year the availability is 97.3% per year. MH's transmission customers did not want to pay some $800 million in capital costs for a second 500 kV line to increase the Firm Transmission Service availability by 2%, especially considering that Firm Transmission Service loss does not result in loss of load, but results in a call for redispatch (call for Operating Reserves being carried to cover for loss of the largest generator or largest loaded transmission line with associated fast generation runback (SPS)). The inability to interrupt Firm Transmission Service will drive expensive new line construction, or require withdrawal of 1500 MW of firm transmission service from the market. P4: Greater than 300 kV - Interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer. The low probability of P4 events does not warrant the cost of raising the reliability performance requirements.

Organization	Question 7:	Question 7 Comments:
		P5: Greater than 300 kV - Interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer. NERC defines a Protection System as "Protective relays, associated communication systems, voltage and current sensing devices, station batteries and DC control circuitry. In many cases, the protective relays, associated communication circuits and DC control circuits consist of two separate or redundant systems, but the voltage and current devices and station battery may be common. Is the SDT considering a current sensing device, or the station battery, for example, to be a single point of failure? Table 1 Note 4: Imposes a requirement on FACTS devices, and therefore should be elevated to the Requirements in the standard body. Also FACTs devices can be put in a series connection as well as shunt. Perhaps some additional clarification is required. Additional Comments on Table 2: Stability Performance Requirements: ?The Performance Requirements (Items 1 to 5) should have a heading "Evaluation Requirements". These evaluation requirements should be included in the standard body. Also they should be labeled A to E to avoid confusion with the Notes at the end of the Table 2 – Item 4: should the simulation also include the effect of reclosing where applicable? Planning Events: Same as comments on Table 1 regarding treatment of Firm Transmission Service and Non-Consequential Load Loss for >300 kV P4: Greater than 300 kV - Interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer. P5: Greater than 300 kV - Interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer. Multiple Contingency events (P3, P6): Does the SDT envision these multiple events being simulated as a stability run for the second event using a base case with an adjusted system - considering the first event is typically P1 which has been previously run as a separate simulation, typically a P1 event? P5: see Table 1 comment re what is considered a single point of failure. Extreme Events: Evaluation Requirement 1 - R5.5.4 should be R5.4.4 Extreme Event Description 2H: A 3 phase bus fault on a switching station would not normally result in loss of a voltage level and transformers at a station. The event should just be loss of one voltage level plus transformers in a substation. Table 2 Notes: Suggest changing "Notes" to "Table 2 Notes" if more than one table is retained. Note 5 a. Stipulates requirements for generating unit performance - should not be buried in the notes. Also, what is the SDT rationale for allowing units to pull out of synchronism for single contingency events like P2, or P5 - stuck breaker, or P7 - common tower, which is a normal clearing event.

Organization	Question 7:	Question 7 Comments:
		P1: Similar to DC lines, interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer. P3: Similar to DC lines, interruption of Firm Transmission Service should be allowed if transfer is dependent on the outaged AC transmission line or transformer. It is important for a probabilistic measure of likelihood to be considered in designing Table 1 and Table 2. The various categories of contingencies, P1 to P7, for example, should be ideally arranged in order of magnitude of likelihood, so that the acceptable consequences or the performance requirements may be in an increasing level of severity. However, there are events with intrinsically different probabilities currently classified within each of these contingency categories. For example, in P3 (following loss of a generator followed by system adjustments), another generator forced outage is more likely than a transformer forced outage. In P2 (single contingency), loss of a bus section is less likely than the P3 event of a double generator contingency. Therefore, these P categories, as currently defined, overlap one another in the scale of likelihood. As a result of it, Table 1 and Table 2 have allowed for certain rarer events (e.g., included in single-contingency P2 and double-contingency P3 categories) to incur some significant consequences with unspecified limits, e.g., interruption of firm transmission services or "non-consequential" load loss. It may be better to follow the NERC Reliability Concepts White Paper's approach of displaying these tables in categories of event likelihood, so that the acceptable consequences would be in an increasing level of severity. This approach would then be consistent with Probabilistic Risk Assessment, when the industry has collected enough transmission outage data to enable such a method be applied. Though the US power industry does not have transmission outage statistics collected and analyzed across the industry, Canadian utilities do have excellent data. It seems to be possible for the various contingency events in the current Tables 1 and 2 to be recategorized according to five or six groups of "order of magnitude of likelihood", e.g., M0, M1, M2, M3, M4 and M5. Each order of magnitude of likelihood is ten times less likely than the preceding order. For example, the first order (M1) would be for outage probabilities greater than 1%. The second order (M2) would be for outage probabilities between 0.1% and 1%. The third order (M3) would be between 0.01% and 0.1%, etc. Multiple independent contingencies could be classified based on the product of their individual probabilities, e.g., a generator outage is of order M1, and a transmission circuit outage is of order M2. Therefore, a double contingency of a generator and a transmission circuit is of order M3, but a double generator contingency is of order M2. Having placed the initiating contingencies in these orders of likelihood, it is then feasible for the industry stakeholders to try to agree on the level of acceptable consequences for these magnitude orders of likelihood. In the current draft of this standard, there is no quantified variable degree of acceptable consequences, as envisioned in the NERC Reliability Concept White Paper.There is distinctly different treatment of whether the out-of-service element is below or above 300KV. There is difference in allowing or not allowing firm transaction interruption and/or non-consequential load loss, but neither of them has a specified limit on the MW amounts. With the current layout of Tables 1 and 2, it is not readily apparent that the proposed standard is consistent with a sound risk approach. Having a sound risk approach is very important because investment decisions will be made according to these new, proposed and still-deterministic standards. Planners may find out in their studies that the costs of meeting some unlikely contingencies requiring expensive transmission investments are very high and that these costs are not justifiable based on avoiding those rare consequences. On the other hand, because the amounts of acceptable firm transaction interruption and non-consequential load loss are not specified, the transmission system designed to that

Organization	Question 7:	Question 7 Comments:
		standard with unspecified limits may become vulnerable to cascading events that initiate in the transmission grid below 300 KV. Many entries in the Tables allow non-consequential load losses, but no limits are specified. It raises the question, "If any non-consequential load loss is acceptable, is there a need to study that contingency scenario?" Without a reasonable set of limits, the criteria may not be effective in assuring system reliability. NERC's event analysis group has been using five categories of consequences to classify recent blackouts or major disturbances. A condensed summary of this is as follows. Category 1. Abnormal frequencies > 5min; or inter-area oscillations Cateorgy 2. System separation with no loss of load or generation; or loss of generation (between 1,000 and 2,000 MW in the EI or WI and between 500 MW and 1,000 MW in ERCOT) Category 3. Loss of load (less than 1,000 MW); or loss of generation (> 2,000 MW in the EI or WI and > 500 MW in ERCOT); System separation or islanding with loss of load or generation (less than 1,000 MW). Category 4. System separation or islanding of more than 1,000 MW of load; or loss of load (1,000 to 9,999 MW). Category 5. Loss of load (10,000 MW or more) Lay persons as well as transmission planners can understand and appreciate these ways of defining consequences, e.g., category 5 events mean more than 10,000 MW of load or generation loss. A way to propose reasonable limits to the highly unlikely but potentially severe contingencies, e.g., M3, M4, and M5, would be to limit their designed consequences to Category 2, 3 or 4. A well designed transmission system should limit the consequences of potential cascading outages and their likelihood so that fewer major blackouts would occur, while balancing the cost of investment to the cost of outages to the customers. A number of utilities are already performing PRA studies for their transmission planning. The advantages of using PRA have been demonstrated in the nuclear power industry. It would be desirable to have a pathway for the power industry to transition from the still-deterministic planning criteria in TPL-001 to a probabilistic planning criteria, without having to wait for another major revision to the TPL standard. If the Tables 1 and 2 are arranged and presented consistently with the NERC Reliability Concepts White Paper, the approach will enable that transition to take place naturally. If the TPL-001 standards establish a PRA-compatible Table 1 and Table 2, with contingency categories sorted in order of magnitude of likelihood, and their acceptable consequences also arranged in order of consequences (such as the five categories), the reliability requirement is already seen in the PRA-compatible way of a constant Risk level, Risk = Likelihood x Consequence. When the industry has good data to quantify the probabilities of these various contingencies, the implication of this ?already-accepted? Risk Level would be clear and numerically expressable. What is useful at this time is for the industry to make a forward-looking estimate of what this Risk level would be like, and consider whether it is appropriate and consistent with sound economic and risk principles.

Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The move to a single table was based on a significant number of comments and based on the SDT’s view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.

The top introductory notes have been retained and are now referred to alphabetically to avoid confusion with the referenced footer notes. The top notes also

Organization	Question 7:	Question 7 Comments:

better clarify which are applicable to steady-state, stability or both.

The standard does not place a limit on the amount of Non-Consequential Load loss allowed. However, the maximum Consequential Load loss and its associated Contingency require documentation. See Requirements R2.9 and 2.10.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

R2.9 The Planning Assessment shall identify the maximum permissible Non-Consequential Load Loss (megawatt Demand) for those Planning Events where Non-Consequential Load Loss is allowed in Table 1.

In regards to the Planning Event P3, the SDT team agrees with the commenter's opinion on the need to allow for all types of conditional Firm Transmission Service interruptions and that the prior Draft 2 version unintentionally provided preferential treatment to HVDC. In the new performance Table 1, a new footnote has been added (see footnote 5) to the column title "Interruption of Firm Transmission Service Allowed" that corrects the problem identified by the commenter. The SDT believes that interruption of Firm Transmission Service may be justified, so long no firm load loss occurs if the performance requirements do not permit the load shed. See new footnote 10 regarding the SDT stance on interruption of Firm Transmission Service and its use in multiple contingency Planning Events.

In regards to Planning Event P2.1, the reference to "single ended" has been removed and footnote 8 was added to further clarify the event required for study.

Based on feedback received the SDT was not compelled to alter its stance on the provision for Non-Consequential Load shed for a P4 and P5 event. However, the SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained.

The SDT has revised the P5 Planning Event description to remove the reference to "single component failure" and the event description was changed to match what is stated in the currently approved TPL standards under Category C6 through C9. The intent of P5 is to evaluate a failure of a single Protection System design that introduces a delayed clearing mode that may also include additional electrical Facilities being removed when compared to the normal fault clearing. A Protection System failure resulting in loss of the substation (one voltage level plus transformers) would not qualify as a P5 Planning Event since that event is considered an Extreme Event. A Standard Authorization Request (SAR) has been issued for industry comment (1/20/2009 through 2/18/2009) based on work completed by the System Protection and Controls Task Force (SPCTF). The proposed project will address the need for Protection System redundancy, based on an n-1 failure of individual components of the Protection System.

The SDT agrees that FACTS can be series devices and the footnote reference has been modified to better clarify the intent is shunt devices, connected to ground. See footnote 7.

7. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground.

The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of

Organization	Question 7:	Question 7 Comments:
comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The requirements do not require study of reclosing actions. Only the initial Protection System responses must be simulated. P3 – see above response for Table 1. Based on feedback received the SDT was not compelled to alter its stance on the provision for Non-Consequential Load shed for a P4 and P5 event. However, the SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained. In the multiple Contingency P3 (Gen + 1) and P6 (N-1-1), within a stability study only the 2nd outage is required to be reviewed. The first Contingency is a precondition that needs to be modeled but not evaluated for its Stability response if the P3 or P6 condition is studied for Stability. The SDT has revised the P5 Planning Event description to remove the reference to "single component failure" and the event description was changed to match what is stated in the currently approved TPL standards under Category C6 through C9. The intent of P5 is to evaluate a failure of a single Protection System design that introduces a delayed clearing mode that may also include additional electrical Facilities being removed when compared to the normal fault clearing. A Protection System failure resulting in loss of the substation (one voltage level plus transformers) would not qualify as a P5 Planning Event since that event is considered an Extreme Event. A Standard Authorization Request (SAR) has been issued for industry comment (1/20/2009 through 2/18/2009) based on work completed by the System Protection and Controls Task Force (SPCTF). The proposed project will address the need for Protection System redundancy, based on an n-1 failure of individual components of the Protection System. In the Extreme Events area of the Stability table the reference to Requirement R5.5.4 has been removed due to a circular reference between the requirements and the table. The Extreme Event item 2h is written consistent with the presently approved TPL D8 and D9 contingencies. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The SDT team agrees with the commenter's opinion on the need to allow for all types of conditional Firm Transmission Service interruptions and that the prior Draft 2 version unintentionally provided preferential treatment to HVDC. In the new performance Table 1, a new footnote has been added (see footnote 5) to the		

Organization	Question 7:	Question 7 Comments:
column title "Interruption of Firm Transmission Service Allowed" that corrects the problem identified by the commenter Regarding bottom note 5a, now shown as footnote 1, the SDT believes that no unit should be allowed to pull out of synchronism for more likely single Contingency events such as a three-phase fault on a line, transformer, or generator - a P1 event. The P2 events, even though classified as single Contingency events with normal clearing, are less likely to occur (bus faults, internal breaker faults, etc.). P5 and P7 are multiple Contingency events and are less likely to occur. The SDT believes it is appropriate to allow units to pull out of synchronism for less likely events as long as the other conditions of footnote 1 are maintained. The Planning Events, in general are ordered based on level of probability. However, the SDT chose to order the table by three main areas: 1) no Contingency (P0), 2) single Contingency (P1, P2) and 3) multiple Contingency (P3 through P7). While the SDT agrees with the commenter that there is some overlap in probability order, for example between P2 and P3, we believe the SDT has more importantly made the proper performance level requirements based on a reliability "risk" level where risk accounts for impact times (x) probability of occurrence. The commenter's proposed shift from deterministic planning to probabilistic planning is outside the scope of the SAR for this project. The SDT believes the commenters suggested focus on more detailed probabilistic analysis is better addressed after the industry obtains additional outage data and insight obtained through the TADS effort.		
Los Angeles Department of Water and Power	No	The performance table allows different performance for same contingency at different voltage classes that is arbitrary separated. This is discriminatory and without any scientific or historical basis. There should be only one class for the whole transmission system. Transmission system at below 300kV should not be granted preferential treatment. Mindful also that the initiating causes of last two major continental wide blackouts(one in WECC and the other in the Eastern Interconnections) both started in system at less than 300kV.
Response: The SDT believes it has provided sufficient reasoning why the above 300 kV System should be held to a higher standard. The initial draft of the proposed Transmission planning standard held the planning of 300 kV and higher Transmission Systems to a more stringent requirement than the remaining BES. Although not unanimous, the majority of the SDT believed the 300 kV and higher Systems (EHV) generally represent the backbone of many Systems in the various Interconnections and that the more stringent requirements were appropriate when considering N-1-1 Contingencies of two EHV Facilities. Systems operated above 300 kV generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers where the energy is then delivered by other Transmission or sub-Transmission Systems to end-use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. Additionally, loss of the EHV system stresses the lower voltage parallel paths. EHV transformers can be exposed to long duration outages. Therefore, it was the conclusion of the SDT in Draft 1 to propose greater reliability and operational flexibility through more stringent performance requirements when considering certain N-1 and N-1-1 Contingency events of EHV Systems. Throughout the industry, substation arrangements at EHV levels reflect the importance of these Systems as the designs often consist of the more flexible and reliable ring-bus, breaker-and–a-half or double bus-double breaker protection schemes as compared to the simpler, lower cost single bus arrangements that are commonly found on lower voltage systems. The feedback received from the industry was divided related to the SDT's emphasis placed on a higher expectation for the 300 kV and higher systems. Some commenters questioned the importance and the high costs that may be needed to mitigate existing system designs. Others agreed with the SDT's approach and indicated that the impact to their systems would be minimal. Some commenters even questioned why the more stringent approach was not applied to the entire		

Organization	Question 7:	Question 7 Comments:
100 kV and higher systems. The SDT believes the Draft 2 changes are responsive to industry feedback and reflect an appropriate middle ground related to the importance of the EHV Transmission System.		
Transmission Agency of Northern California	Yes and No	We do not disagree with the proposed format changes of the Tables. However, we are not sure if separating into two Tables is necessary, or beneficial. It seems like an extra column for event could be added and some changes to the notes would greatly simplify the table. Some of the rows could also be combined; one such example is P2-2 (Loss of Bus Section) and P2-3 (Internal Breaker Fault, non-bus-tie). Will the SDT plan on combining some similar rows? Table 1, P4 and P5 refer to "Faults" as part of the contingency. This is steady state performance and faults are not modeled in steady state. Table 1, P2.1 refers to a "single ended line". Technically, this means we need to generate a "false" bus at each end of the line to evaluate this condition or use a dispatcher power flow which included breaker modeling. Is this an accurate interpretation of the intent of this requirement? We believe there should be no distinction between the voltage classes and support the use of load shed for all cases identified in P4 through P7.
Public Service Company of New Mexico	Yes and No	We do not disagree with the proposed format changes of the Tables. However, we are not sure if separating into two Tables is necessary, or beneficial. It seems like an extra column for event could be added and some changes to the notes would greatly simplify the table. Please explain/define the term "single ended line" used in Table 1, P2.1. We believe there should be no distinction between the voltage classes and support the use of load shed for all cases identified in P4 through P7.
Alberta Electric System Operator	No	We do not agree with the proposed format changes of the Tables, separating into two Tables is not necessary, or beneficial. It seems like an extra column for event could be added and some changes to the notes would greatly simplify the table. Some of the rows could also be combined; one such example is P2-2 (Loss of Bus Section) and P2-3 (Internal Breaker Fault, non-bus-tie). Will the SDT plan on combining some similar rows? Table 1, P4 and P5 refer to "Faults" as part of the contingency. This is steady state performance and faults are not modeled in steady state. Table 1, P2.1 refers to a "single ended line". Technically, this means we need to generate a "false" bus at each end of the line to evaluate this condition or use a dispatcher power flow which included breaker modeling. Is this an accurate interpretation of the intent of this requirement? We believe there should be no distinction between the voltage classes and support the use of load shed for all cases identified in P4 through P7.
US Bureau of Reclamation	No	We do not disagree with the proposed format changes of the Tables. However, we are not sure if separating into two Tables is necessary, or beneficial. It seems like an extra column for event could be added and some changes to the notes would greatly simplify the table. Some of the rows could also be combined; one such example is P2-2 (Loss of Bus Section) and P2-3 (Internal Breaker Fault, non-bus-tie). Will the SDT plan on combining some similar rows? Table 1, P4 and P5 refer to "Faults" as part of the contingency. This is steady state performance and faults are not

Organization	Question 7:	Question 7 Comments:
		modeled in steady state. Table 1, P2.1 refers to a "single ended line". Technically, this means we need to generate a "false" bus at each end of the line to evaluate this condition or use a dispatcher power flow which included breaker modeling. Is this an accurate interpretation of the intent of this requirement? We believe there should be no distinction between the voltage classes and support the use of load shed for all cases identified in P4 through P7.

Response: The SDT agrees with the commenter related to the prior two table format and based on feedback received from the Draft 2 standard the SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The SDT believes the commenter will find that the new format is greatly condensed and more user friendly from a readability view.

The commenter is correct that the use of the term “fault” in the P4 and P5 events is not needed from a steady-state view; however, the SDT felt the term is needed to accurately describe the event to be analyzed. From a steady-state perspective, only the resulting condition would be analyzed. Also, with the combined format the term is now better used as the Planning Events also describe the type of fault to be studied within a Stability study. Footnote 3 clarifies that the type of fault is referenced only for the Stability studies.

In regards to the P2.1 event, the intent is to capture a potential condition of serving Load that is tapped from a normally networked line from a single source location. If a line exists (breaker to breaker) that does not directly serve Load, the P2.1 condition would not apply and only the normal N-1 condition of the line would be studied. See the newly added footnote 8 that better describes the intent of the P2.1 Planning Event.

The SDT believes it provided sufficient justification in its Draft 1 response as to why a greater expectation is placed on the above 300 kV (EHV) system. The feedback received from the industry was divided related to the SDT’s emphasis placed on a higher expectation for the 300 kV and higher systems. Some commenters questioned the importance and the high costs that may be needed to mitigate existing system designs. Others agreed with the SDT’s approach and indicated that the impact to their systems would be minimal. Some commenters even questioned why the more stringent approach was not applied to the entire 100 kV and higher systems. The SDT believes the Draft 2 changes are responsive to industry feedback and reflect an appropriate middle ground related to the importance of the EHV Transmission System.

Based on feedback received the SDT was not compelled to alter its stance on the provision for non-consequential load shed. However, the SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained.

5. When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

Organization	Question 7:	Question 7 Comments:
National Grid	No	a. In the column "Interruption of Firm Transmission Service Allowed" in both Tables 1 and 2, it is problematic to try to create an "exemption" based on type of facility such as HVDC. There are many other situations in which Firm Transmission Service has been provided, but may need to be curtailed partially or completely following an outage. b. The term 'Firm' may have several different definitions. If 'Firm' Transmission Service or load may be interrupted for exceptional events, then it is conditional and 'Conditional Firm' should be defined. It is recommended that a note be added stating that "the only exception would be for curtailment of conditioned (or Conditional) Firm Transmission Service", recognizing that there may need to be some form of grandfathering in order to avoid having to rewrite transmission service agreements. c. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." d. In Table 1, the "Extreme Event Descriptions" items 3a and 3b should be deleted; they are redundant with Item 1. e. In Table 2, Note 5 includes significant clarifications and should not be buried in the bottom of the contingency table; Note 5 would be better placed in the definitions section. f. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure. Assuming that the battery system is included in the Protection System, which it is in NPCC, then ALL protection at substations with single battery systems would be lost. This Contingency P5 requires a stable system response while all bus voltages and loadings to remain within criteria, without interruption of firm transmission service and without Non-Consequential Load Loss, at system voltages above 300 kV. Was this an intended outcome of this standard?
Central Maine Power Company	No	a. In both Table 1 and Table 2, the "Interruption of Firm Transmission Service Allowed" column. It is problematic to try to create an "exemption" based on type of facility such as HVDC. There are many other situations in which Firm Transmission Service has been provided, but may need to be curtailed partially or completely following an outage. b. The term 'Firm' may have several different definitions. If 'Firm' Transmission Service or load may be interrupted for exceptional events, then it is conditional and 'Conditional Firm' should be defined. It is recommended that a note be added stating that "the only exception would be for curtailment of conditioned (or Conditional) Firm Transmission Service", recognizing that there may need to be some form of grandfathering in order to avoid having to rewrite transmission service agreements. c. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." d. In Table 1, the "Extreme Event Descriptions" items 3a and 3b should be deleted; they are redundant with Item 1. e. In Table 2, Note 5 includes significant clarifications and should not be buried in the bottom of the contingency table; Note 5 would be better placed in the definitions section.

Organization	Question 7:	Question 7 Comments:
		f. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure. Assuming that the battery system is included in the Protection System, which it is in NPCC, then ALL protection at substations with single battery systems would be lost. This Contingency P5 requires a stable system response while all bus voltages and loadings to remain within criteria, without interruption of firm transmission service and without Non-Consequential Load Loss, at system voltages above 300 kV. Was this an intended outcome of this standard?
NSTAR Electric	No	1. Referring to both Table 1 and Table 2, the "Interruption of Firm Transmission Service Allowed" column, it is problematic to try to create an "exemption" based on the type of facility such as HVDC. There are situations in which Firm Transmission Service has been provided, but may need to be curtailed partially or completely following an outage. The term 'Firm' may have several different definitions. If 'Firm' Transmission Service or load may be interrupted for exceptional events, then it is conditional and 'Conditional Firm' should be defined. It is recommended that a note be added stating that "the only exception would be for curtailment of conditioned (or Conditional) Firm Transmission Service", recognizing that there may need to be some form of grandfathering in order to avoid having to rewrite transmission service agreements. 2. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." 3. In Table 1, the "Extreme Event Descriptions" items 3a and 3b should be deleted; they are redundant with Item 1. 4. Table 2, Note 5 includes significant clarifications which should not be buried in the back; they are better placed in the definitions section. 5. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure. Protection System Failure should be defined and noted if the battery system is included.
New York Independent System Operator	No	In both Table 1 and Table 2, the "Interruption of Firm Transmission Service Allowed" column. It is problematic to try to create an "exemption" based on type of facility such as HVDC. There are many other situations in which Firm Transmission Service has been provided, but may need to be curtailed partially or completely following an outage. It is recommended that a note be added stating that the only exception would be for curtailment of conditioned (or Conditional) Firm Transmission Service, recognizing that there may need to be some form of grandfathering in order to avoid having to rewrite transmission service agreements. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." In Table 1, the "Extreme Event Descriptions" item 3b should be deleted; it is redundant with Item 1. In Table 2, Note 5 includes significant clarifications and should not be buried in the bottom of the contingency table; Note

Organization	Question 7:	Question 7 Comments:
		5 would be better placed in the definitions section. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure, such as a battery system which may remove ALL protection at some substations. This Contingency P5 requires all voltages and loadings to remain within criteria, and a stable system response; without interruption of firm transmission service and without Non-Consequential Load Loss, at voltages above 300 kV. Was this an intended outcome of this standard?
ISO New England Inc.	No	a. In both Table 1 and Table 2, the "Interruption of Firm Transmission Service Allowed" column. It is problematic to try to create an "exemption" based on type of facility such as HVDC. There are many other situations in which Firm Transmission Service has been provided, but may need to be curtailed partially or completely following an outage. b. The term 'Firm' may have several different definitions. If 'Firm' Transmission Service or load may be interrupted for exceptional events, then it is conditional and 'Conditional Firm' should be defined. It is recommended that a note be added stating that "the only exception would be for curtailment of conditioned (or Conditional) Firm Transmission Service", recognizing that there may need to be some form of grandfathering in order to avoid having to rewrite transmission service agreements. c. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." d. In Table 1, the "Extreme Event Descriptions" items 3a and 3b should be deleted; they are redundant with Item 1. e. In Table 2, Note 5 includes significant clarifications and should not be buried in the bottom of the contingency table; Note 5 would be better placed in the definitions section. f. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure. Assuming that the battery system is included in the Protection System, which it is in NPCC, then ALL protection at substations with single battery systems would be lost. This Contingency P5 requires a stable system response while all bus voltages and loadings to remain within criteria, without interruption of firm transmission service and without Non-Consequential Load Loss, at system voltages above 300 kV. Was this an intended outcome of this standard?

Response:

The SDT agrees with the commenter's opinion on the need to allow for all types of conditional Firm Transmission Service interruptions and that the prior Draft 2 version unintentionally provided preferential treatment to HVDC. In the new performance Table 1, a new footnote has been added (see footnote 5) to the column title "Interruption of Firm Transmission Service Allowed" that corrects the problem identified by the commenter.

The SDT agrees with the commenter that interruption of Firm Transmission Service may be justified, so long as firm Non-Consequential Load is not interrupted if the performance requirements do not permit the Load shed. See new footnote 10 regarding the SDT stance on interruption of Firm Transmission Service and its use in multiple Contingency Planning Events.

Organization	Question 7:	Question 7 Comments:
The SDT agrees that shunt devices were excluded in Extreme Event item 1 of the Steady-State and Stability tables and the problem has been corrected. The SDT agrees with the commenter regarding the opinion that item 3B in the Extreme Event portion of the prior Daft 2 Table 1 Steady-State was redundant and the item has been removed and is no longer referenced in this draft. **Extreme Events - 3b**. ~~Loss of two Transmission lines in different rights-of-way prior to System adjustments for conditions such as:~~ The SDT appreciates the input related to the footnote on "System Stable" (new footnote 1) but the SDT chose to keep it as a footnote reference for convenience to the TPL standard and not include it as a new definition for the NERC Glossary of Terms as suggested by the commenter. Related to the P5 "Protection System Failure" Planning Event the SDT has not deviated from its stance of requiring more stringent performance requirements for the above 300 kV System. The SDT has revised the P5 Planning Event description to remove the reference to "single component failure" and the event description was changed to match what is stated in the currently approved TPL standards under Category C6 through C9. The intent of P5 is to evaluate a failure of a single Protection System design that introduces a delayed clearing mode that may also include additional electrical Facilities being removed when compared to the normal fault clearing. A Protection System failure resulting in loss of the substation (one voltage level plus transformers) would not qualify as a P5 Planning Event since that event is considered an Extreme Event. A Standard Authorization Request (SAR) has been issued for industry comment (1/20/2009 through 2/18/2009) based on work completed by the System Protection and Controls Task Force (SPCTF). The proposed project will address the need for Protection System redundancy, based on an n-1 failure of individual components of the Protection System.		
Tenaska, Inc.	Yes and No	Should add a column to the tables indicated when automatic generation runback/tripping is allowed.
Response: Redispatch of generation is allowed for all Planning Events provided that all Facilities shall be operating within their Facility Ratings and within their thermal and voltage limits. The requirement has been removed and replaced with Table 1 header note "e" since the text in the former requirement was explanatory of what was allowed and not requirement language. **Header note 'e'**: For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.		
Gainesville Regional Utilities	No	Some of the notes at the top of each table could be considered to apply to some of the events within the table that conflict in part with the standard and with what was stated in the nation wide phone conference. I would also like to see a note in the tables that reflect a technical rationale for the range of elements considered, since some may be impractical and of no technical value for contingencies involving certain facilities especially those on the smaller systems within the interconnected region.
Response: The SDT has adjusted the top notes and refer to them with alpha character references to avoid confusion with the table footnotes that are referenced within the table. The set of Contingencies considered are not greatly different than those in the currently approved TPL suite of standards. We have attempted to add simplicity as to those Contingencies that are deemed to be Planning Events, thus requiring corrective action plans, and the Extreme Events which do not require corrective action plans.		

Organization	Question 7:	Question 7 Comments:
ITC Holdings: ITC, METC, ITC Midwest	Yes and No	While we like the tables, we don't understand what ?Interruption of Firm Transmission Service Allowed? means in a stability study (as per table 2). How would you interpret that in real-time & study terms? Would you make the stability scenario a limit to selling transmission service? In table 2, should we interpret SLG or 3-phase Fault in P1 and P3 to mean that SLG is the criteria (minimum) but you can run and document the more severe 3 phase faults for compliance purposes? What is the minimum criteria?
Response: The SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained. In some instances, it may be necessary to interrupt Firm Transmission Service in preparation for the studied condition. It could be that from a Stability point of view such action would be beneficial under some conditions. **Footnote 5.** When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. The SDT has corrected the confusion related to the "SLG or 3-phase" fault reference that the commenter describes in the P1 Planning Event. The table now says 3-phase. We added footnote #3 to clarify the fault types and what study results are sufficient for the case of an SLG fault condition. **3.** Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø fault study indicating criteria are being met shall provide sufficient evidence that a SLG condition would also meet criteria.		
Hydro-Quebec Transenergie (HQT)	No	In both Table 1 and Table 2, the "Interruption of Firm Transmission Service Allowed", a definition should be provided to clarify that term. That term is more of a Market concept not used by all TOs and defined in their Transmission Tariff. Also, the standard might need to introduce a new term "Consequential Transmission Service Loss" as it does for the Load. Firm Transmission services are generally defined as a service of the same priority as the one for the native load. That does not mean it could not be interrupted. In both Table 1 and Table 2, the "Extreme Event Descriptions" item 1 should add "or shunt device." In Table 1, the "Extreme Event Descriptions" item 3b should be deleted; it is redundant with Item 1.

Organization	Question 7:	Question 7 Comments:
		In Table 2, Note 5 includes significant clarifications and should not be buried in the bottom of the contingency table; Note 5 would be better placed in the definitions section. In Table 1 and Table 2, Contingency P5 requires a fault plus Protection System Failure. The "Protection System Failure" aspect of this contingency brings the necessity to define more clearly what is intended. The notion of needed redundancy or single elements of the protection system, be it physical or electric, has to be addressed to clearly understand the implication of that contingency. Until such clarification is included in this standard or in the future "Redundancy standard", this contingency should not be effective.

Response: The NERC Glossary of Terms presently defines Firm Transmission Service as “The highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption.” FERC in Order 693 was clear that no planned interruption of Firm Transmission Service should be permitted for single Contingency conditions. We agree that there may be times when Firm Transmission Service should be permitted. The SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained.

5. When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

Footnote #10 – Curtailment of firm transmission service , when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled ‘Initial System Conditions’) and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner’s planning region are relied upon, Facility Ratings in those regions must be considered.

The SDT agrees that shunt devices were excluded in Extreme Event item 1 of the Steady-State and Stability tables and the problem has been corrected.

Extreme Event Steady State #1

Loss of a single generator, Transmission Circuit, DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, DC Line, shunt device, or transformer forced out of service prior to System adjustments.

The SDT agrees with the commenter regarding the opinion that item 3B in the Extreme Event portion of the prior Daft 2 Table 1 Steady-State was redundant and the item has been removed and is no longer referenced in this draft.

Extreme Event – Steady State:

3b. ~~Loss of two Transmission lines in different rights-of-way prior to System adjustments for conditions such as:~~

The SDT appreciates the input related to the footnote on “System Stable” (new footnote 1) but the SDT chose to keep it as a footnote reference for convenience

Organization	Question 7:	Question 7 Comments:
to the TPL standard and not include it as definition for the NERC Glossary of Terms as suggested by the commenter. Related to the P5 "Protection System Failure" Planning Event the SDT has not deviated from its stance of requiring more stringent performance requirements for the above 300 kV System. The SDT has revised the P5 Planning Event description to remove the reference to "single component failure" and the event description was changed to match what is stated in the currently approved TPL standards under Category C6 through C9. The intent of P5 is to evaluate a failure of a single Protection System design that introduces a delayed clearing mode that may also include additional electrical facilities being removed when compared to the normal fault clearing. A Protection System failure resulting in loss of the substation (one voltage level plus transformers) would not qualify as a P5 Planning Event since that event is considered an Extreme Event. A Standard Authorization Request (SAR) has been issued for industry comment (1/20/2009 through 2/18/2009) based on work completed by the System Protection and Controls Task Force (SPCTF). The proposed project will address the need for Protection System redundancy, based on an n-1 failure of individual components of the Protection System.		
Progress Energy Florida, Inc.	No	The Steady State and Stability Tables (Tables 1 and 2), are overly long, confusing, and contain circular references. PEF strongly advises returning to the content and format of Table 1 in the existing TPL Standards, or at the very least, consolidation of the Tables into a single Table. Furthermore, for certain events in Tables 1 and 2, the SDT's intent concerning the scope of the events and how the events would be simulated in Transmission Planning analyses is not clear. PEF furthermore does not agree with "Interruption of Firm Transmission Service Allowed" and "Non-Consequential Load Loss Allowed" as benchmarks for whether or not a particular BES is reliable (see additional comments in Question 15 on this issue). Tables 1 and 2 at present are 13 pages in total, whereas the existing Table 1, which PEF feels is comprehensive and not in need of revision, is merely 1.5 pages long. PEF understands that the reason behind the length and complexity of Tables 1 and 2 stems from a desire by some to contain all of the primary TPL compliance issues in a tabular format. The end result, however, is not effective and must be made more concise.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. The new format more closely mimics the existing TPL table in its readability. The set of Contingencies considered are not greatly different than those in the currently approved TPL suite of standards. The SDT has attempted to add simplicity as to those Contingencies that are deemed to be Planning Events, thus requiring corrective action plans, and the Extreme Events which do not require corrective action plans. The change in performance expectations for the above 300 kV System are supported by many in the industry. Please see our response to Q15 for further information.		
Ameren	Yes	The tables could be improved by including the column headings on each page.

Organization	Question 7:	Question 7 Comments:
		Separating the steady-state and stability performance requirements for each planning event helps to provide clarification.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.		
City of Tallahassee, FL	Yes and No	while this was an improvement, the tables are still confusing and make determination of the compliance requirements difficult. Especially where there are multiple events within a single event category (like P3 or P6) there's confusion about what would be allowed between the two element outages.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments to do so and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. The SDT believes the changes improve the readability of the tables. There are concerns expressed by numerous respondents that after the first single Contingency and System adjustment, curtailment of Firm Transmission Services (or firm transfers) and shedding of firm Load would not be allowed in preparation for the second Contingency. The SDT added Footnote # 10 to the end of Table 1 to reflect that Curtailment or Interruption of Firm Transmission Service in preparation for the next Contingency will be allowed as long as firm Load, not outaged by the initial event, continues to be served. **Footnote #10** – Curtailment of firm transmission service , when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
Florida Power and	No	The Table format is extremely confusing and too long.

Organization	Question 7:	Question 7 Comments:
Light		The allowed and disallowed actions as well as the applicable time frames for them is not clearly stated. The tables 1 &2 should be combined and condensed so that they can be read more easily. In their current format, these tables sprawl across 13 pages. The use of footnotes or expanded information in the Table headings is needed to understand the performance requirements.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The move to a single table was based on a significant number of comments to do so and based on the SDT’s view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. The SDT believes the changes improve the readability of the tables. The changes to the new table have removed the need for repeat headers. Regarding the commenter’s statement “The allowed and disallowed actions as well as the applicable time frames for them is not clearly stated.” It is assumed that this is in reference to the P6 N-1-1 Planning Event. There are concerns expressed by numerous respondents that after the first single Contingency and System adjustment, curtailment of Firm Transmission Services (or firm transfers) and shedding of firm Load would not be allowed in preparation for the second Contingency. The SDT added Footnote # 10 to the end of Table 1 to reflect that Curtailment or Interruption of Firm Transmission Service in preparation for the next Contingency will be allowed as long as firm Load, not outaged by the initial event, continues to be served. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled ‘Initial System Conditions’) and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner’s planning region are relied upon, Facility Ratings in those regions must be considered.		
Exelon Transmission Planning	No	Tables 1 and 2 should be changed such that the header should read 'BES Elements Overloaded' rather than 'BES Elements out of Service' regarding the voltage distinction. The header notes should either not be numbered or numbered with a different scheme to differentiate them from the numbered footnotes to avoid confusion. It is not obvious that all of the footnotes are used in the Tables. The headings should be repeated on each page. Could these tables be made smaller by eliminating some of the unused space such as the large boxes containing a single

Organization	Question 7:	Question 7 Comments:
		'x'?
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The move to a single table was based on a significant number of comments to do so and based on the SDT’s view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. The SDT believes the changes improve the readability of the tables. The confusion with regards to the prior “BES Elements Overloaded” has been eliminated in the new table as the prior columns have been deleted. The commenters’ suggestion to repeat table headings was a common response from industry, but is no longer a need based on the new table design. The SDT has now utilized alpha character references for the top notes of the table to avoid confusion with the footnotes which are referenced throughout the table. All footnotes are accounted for with the table and are now referenced sequentially for improved readability.		
CenterPoint Energy and CPS Energy	No	We originally believed that eliminating the old Category A, B, C, and D nomenclature would be beneficial. However, looking at the contingency types now being proposed, we are concerned that more confusion has been created. For example, matching applicable facility ratings to Category A, B, and C conditions is reasonably manageable. Matching applicable facility ratings to 7 contingency "buckets" is more confusing, less manageable, and unnecessary. NYISO proposed the concept of analyzing credible multiple contingencies in the operating realm. Most industry opined that NYISO's proposal lacked merit for operating requirements, and we agreed. However, we believe the proposal may have merit for planning requirements. The concept of applying reasonable credibility criteria to multiple contingencies to be studied offers a way to limit multiple contingency analysis to credible scenarios. Less credible (or incredible) scenarios would then fall into the Extreme category. As proposed, the multiple (seven-fold) approach of categorizing contingencies, combined with various sensitivities or alternative scenarios, for multiple years, is unrealistic and unnecessary. We believe creating a separate table for stability performance might be beneficial, but we believe 7 buckets of contingencies is hopelessly unrealistic for stability analyses.
Response: The set of Contingencies considered are not greatly different than those in the currently approved TPL suite of standards. The SDT tried to better clarify those Contingencies that are deemed to be Planning Events, thus requiring corrective action plans, and the Extreme Events which do not require corrective action plans. Most in industry are receptive to the new Contingency categorization so the TPL SDT has not altered its organization of the performance requirements. The SDT believes the Planning Events describe the credible Contingencies that warrant more rigorous study and the Extreme Events represent the less credible events that need to be reviewed on a more selective basis by the individual transmission planner. In regards to matching an applicable Facility Rating to the 7 Planning Event categories, the SDT believes the 7 categories do not add any additional level of		

Organization	Question 7:	Question 7 Comments:
complexity. The need to cover sensitivity analysis is based on a FERC directive from Order 693 and the SDT believes it is a reasonable request which will drive the industry to better understand their individual Transmission Systems. At this time all Planning Events are still within the scope of possible System conditions that could require a Stability review. The SDT believes the proposed TPL explicitly clarifies that only the “more severe” events require Stability analysis as stated in Requirement R4.4. At this time all Planning Events are still within the scope of possible system conditions that could require a Stability review. The SDT believes the proposed TPL explicitly clarifies that only the “more severe” events require Stability analysis which was implicitly understood within industry for the Version 0 standards as the commenter describes. Many of the conditions described by the commenter could be used as the basis for how a Transmission Planner would select the subset of Planning Events requiring a Stability review.		
MidAmerican Energy Company	No	MEC suggests that the Categories symbols in Table 1 and Table 2 be different to help distinguish between them (e.g. P1:S1, P2:S2, P3.2:S3.2, etc.) MEC suggests that the header text (i.e. Category, Initial System Condition, etc.) be repeated on every applicable page to be more reader-friendly. The superscripts do not refer clearly to the respective notes. (There are numbered notes in the beginning of the table, numbered items in the extreme events evaluation requirements section, numbered items in extreme event description section, and numbered notes at the end of the table). Perhaps the referenced notes should have unique numerology or format to make the superscript references clearer.
MRO NERC Standards Review Subcommittee	No	The MRO suggests that the Categories symbols in Table 1 and Table 2 be different to help distinguish between them (e.g. P1:S1, P2:S2, P3.2:S3.2, etc.) The MRO suggests that the header text (i.e. Category, Initial System Condition, etc.) be repeated on every applicable page to be more reader-friendly. The superscripts do not refer clearly to the respective notes. (There are numbered notes in the beginning of the table, numbered items in the extreme events evaluation requirements section, numbered items in extreme event description section, and numbered notes at the end of the table). Perhaps the referenced notes should have unique numerology or format to make the superscript references clearer.
American Transmission Company	No	We think that the tables are so similar that they should be recombined into one. This would require reasonable adaptation of the tables. If the tables are kept separate, then we suggest that the Categories symbols in Table 1 and Table 2 be different to help distinguish between them (e.g. P1:S1, P2:S2, P3.2:S3.2, etc. We suggest that the header text (i.e. Category, Initial System Condition, etc.) be repeated on every applicable page to be

Organization	Question 7:	Question 7 Comments:
		more reader-friendly. The superscripts do not refer clearly to the respective notes. (There are numbered notes in the beginning of the table, numbered items in the extreme events evaluation requirements section, numbered items in extreme event description section, and numbered notes at the end of the table). Perhaps the referenced notes should have unique numerology or format to make the superscript references clearer.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. This changed has negated the need for the Planning Event category naming convention changes suggested by the commenter and the team retained the P1 through P7 references for Planning Events. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The SDT agrees with the commenter regarding the top notes within the table. We have changed the references to alpha characters to avoid confusion with the footnotes that are referenced with the tables using superscript characters.		
SERC Dynamics Review Subcommittee	Yes	The tables could be improved if the headings were put on each separate page. Separating out the tables for steady state and stability improves and clarifies the requirements of the standard.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. This changed has negated the need for the Planning Event category naming convention changes suggested by the commenter and the team retained the P1 through P7 references for Planning Events. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The move to a single table was based on a significant number of comments and based on the SDT’s view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table.		
Austin Energy	No	Matching facility rating to seven contingency categories is confusing. Furthermore, these seven categories combined with alternative scenarios and sensitivity studies for several years into the future is overly burdensome, unnecessary, and unrealistic.
Response: In regards to matching an applicable Facility Rating to the 7 Planning Event categories, the SDT believes the 7 categories do not add any additional level of complexity. The set of Contingencies considered are not greatly different than those in the currently approved TPL suite of standards. The SDT tried to		

Organization	Question 7:	Question 7 Comments:
better clarify those Contingencies that are deemed to be Planning Events, thus requiring corrective action plans, and the Extreme Events which do not require corrective action plans. Most in industry are receptive to the new Contingency categorization so the TPL SDT has altered its organization of the performance requirements. The need to cover sensitivity analysis is based on a FERC directive from Order 693 and the SDT believes it is a reasonable request which will drive the industry to better understand their individual transmission systems.		
Arkansas Electric Coop. Corp.	No	I disagree with statement #4 for the reasons given in my comments on question 3. Also, if you are going to allow it then consequential generation loss needs to be defined. I also disagree with statement #5. This is a planning standard and as such systems should be planned for planning steady state. Statement #5 should only be allowed if the resulting operator actions are taken into account. A fault on a networked transmission line may open the breakers at each end. Statement #5 stops here when in reality operator actions would isolate the faulted sections and service restored with the transmission line now being operated as two radials. The resulting two radials are what need to meet the performance requirements. Events should be taken to their logical conclusions and the resulting system topology be what meets the performance requirements. The tables need some borders and section dividers. Headers should be on each page. No firm transmission or Non-Consequential Load Loss should be allowed for P2. I think the SDT has it backwards. Non-Consequential Load Loss should never occur and the tables should reflect what is allowed to happen with Consequential Load Loss for each event. Many of the scenarios reflect what should happen with Consequential Load Loss and not Non-Conseqeuntial Load Loss. For example: P2 Bus Section for less than 300 kV -- The load on that bus under this contingency would be Consequential NOT Non-Consequential. For the loss of that bus the load connected to that bus should be ALL the load that is lost, therefore no Non-Consequential Load Loss should occur.
Response: Please see the SDT's response to your question 3 comment regarding your disagreement with statement #4. The SDT concluded from the overall industry comments that a definition for consequential generation loss was not needed and therefore was not added to the standard at this time. The commenter disagrees with statement #5 of the Draft 2 standard which states "Simulate the removal of all elements that Protection Systems and controls are expected to disconnect for each event." However, FERC Order 693 paragraph 1707 references that within the NOPR that preceded the Final Rule "…the Commission believes that the simulations used in planning assessments should faithfully duplicate what will happen in the actual power system and not a generic listing of outages" In paragraph 1716, the Final Rule further clarified that this is the intent of the Commission. Therefore, the wording in the proposed standard. The commenter's disagreement seems to be based on a feeling of needing to plan for no Load drop for single Contingency events; however, in paragraph 1773 it is clear the FERC does allow the loss of Consequential Load. Therefore, Consequential Load Loss that occurs with the initial event is permitted. Serving radial Load tapped from a networked line, from a "singled ended" view or from a single source end (one end of the line open) is covered by Planning Event P2.1 and new footnote 8 should help alleviate the commenter's concerns. Under P2.1 it should be expected that no Load loss would occur. **Footnote 8**: Inadvertent tripping of breakers on one end of a normally networked Transmission circuit such that the line is now open at that end and possibly		

Organization	Question 7:	Question 7 Comments:
serving Load radial from a single source point. The need for headers on each page has been alleviated based on the SDT reformatting of the table to a single table format and greatly condensing the tabular information. The SDT disagrees with the commenter that the SDT “has it backwards” related to the references of Consequential Load Loss and Non-Consequential Load Loss for each event. The performance table accurately depicts when Non-Consequential Load Loss is permitted for various events. Consequential Load Loss is allowed for all events. The table does not try to categorize a type of Load (Consequential or Non-Consequential) that the event is causing to lose electrical service. The initial Protection System actions to the event always trip Consequential Load. The performance table merely clarifies if the Transmission Planner can drop any additional Firm Load (Non-Consequential Load Loss) to alleviate the event and meet performance requirements. In the P2.2 (bus section) event that the commenter references, the difference between the EHV and HV performance requirements is that the Transmission Planner is allowed to drop additional Non-Consequential Load for the HV event.		
Midwest ISO	No	Please add a General Requirements heading before items 1-6 (Steady State) and 1-5 (Stability) which appear to be applicable to all events for each table. The two columns under "BES elements out of Service" could be stricken for simplicity and clarity. If there is a voltage distinction needed, then add it next to the "Yes" or "No" under the "Interuption of Firm Service" or "Loss of Load" columns. Items P0 through P7 are identical in Table 1 - Steady State Performance and Table 2 Stability Performance. The only distinctions are the notes or whether it is an outaged event in Table 1 or a 3 phase/SLG fault in Table 2. Having two tables is redundant and unnecessary, and does not add clarity. It is also recommended that you combine the notes and extreme events from Table 1 - Steady State Performance and Table 2 - Stability Performance into one table. If both tables are to be retained then it is recommended that the SDT take into consideration the following suggestions. With the old Version 0 table, where there was not a separate stability table, it was understood that each of the event types needed to be assessed, but only those that the responsible entity knew were the more severe from a stability perspective needed to have stability analysis performed. By listing events such as single circuit faults (P1) under Table 2, this implies that all events should be simulated with dynamics, though requirement 5.4.1 states events "that would produce more severe System impacts shall be identified,...". The burden to explain why certain events were not selected can be construed now as having to run dynamics on all line faults, or explain why each line was not selected. Most lines embedded within the grid and not near generators or of particular significance to grid dynamic stability need not be studied. We do not believe that the SDT is requiring any additional burden of proof as to why every line in the system is not studied with dynamics, but the standard makes that question more murky than it was before. An overzealous compliance monitor could be confused by the new layout at great expense to the industry. If Table 2 remains, change

Organization	Question 7:	Question 7 Comments:
		Table 2 - Stability Performance to only those events that are important to Stability Analysis. For example the following faults to run would be: 1) Faults near large generators (generator buses, generator lines or transformers near generators)2) Faults with delayed clearing near large generators3) Faults on long or heavily loaded lines with large phase angle differences between terminals. A majority of faults on lines less than 200kV are rarely severe so it is recommended to have the standards reflect this in Table 2 - Stability Performance.
Response: The SDT was persuaded by the commenter and other industry respondents that the two performance tables presented in Draft 2 were redundant in many areas. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance" The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. At this time all Planning Events are still within the scope of possible system conditions that could require a Stability review. The SDT believes the proposed TPL explicitly clarifies that only the "more severe" events require Stability analysis which was implicitly understood within industry for the Version 0 standards as the commenter describes. Many of the conditions described by the commenter could be used as the basis for how a Transmission Planner would select the subset of Planning Events requiring a Stability review.		
Tri-State Generation and Transmission Association, Inc.	Yes and No	It does not seem that there should be different performance limits for DC and AC lines. It is unclear why there is a separation of voltage classes. Perhaps it would be helpful for each TP to specify which voltage levels are considered Bulk on their particular system, then split studies according to that definition. We applaud the SDT's efforts to split contingencies into groups with more-or-less the same system impact. We encourage the SDT that it would be very beneficial to regroup them in order of probability of occurrence, or even better, to group them by order-of-magnitude of occurrence probability. The P categories as now defined seem to overlap in likelihood. For example, in P3 following loss of a generator followed by system adjustments, another generator forced outage is more likely than a transformer forced outage. Loss of a bus section (P2 single contingency) is less likely than the P3 event of a double generator contingency. There is more on the concept of grouping Performance Tables in order of event likelihood in the NERC White Paper, "Reliability Concepts". At the least, notes in the tables - regarding 1) system impact and 2) likelihood of events listed - would be most welcome.
Response: The SDT agrees with the commenter's opinion on the need to allow for all types of conditional Firm Transmission Service interruptions and that the prior Draft 2 version unintentionally provided preferential treatment to HVDC. In the new performance Table 1, a new footnote has been added (see footnote 5) to the column title "Interruption of Firm Transmission Service Allowed" that corrects the problem identified by the commenter. **5**. When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.		

Organization	Question 7:	Question 7 Comments:
The SDT believes it provided sufficient justification in its Draft 1 response as to why a greater expectation is placed on the above 300 kV (EHV) System. The feedback received from the industry was divided related to the SDT's emphasis placed on a higher expectation for the 300 kV and higher Systems. Some commenters questioned the importance and the high costs that may be needed to mitigate existing System designs. Others agreed with the SDT's approach and indicated that the impact to their Systems would be minimal. Some commenters even questioned why the more stringent approach was not applied to the entire 100 kV and higher Systems. The SDT believes the Draft 2 changes are responsive to industry feedback and reflect an appropriate middle ground related to the importance of the EHV Transmission System. The performance requirements only apply to the Bulk Electric System and the split in voltage provides a subset of the BES. The Planning Events, in general, are ordered based on level of probability. However, the SDT chose to order the table by three main areas: 1) no Contingency (P0), 2) single Contingency (P1, P2) and 3) multiple Contingency (P3 through P7). While the SDT agrees with the commenter that there is some overlap in probability order, for example between P2 and P3, the SDT believes it has more importantly made the proper performance level requirements based on a reliability "risk" level where risk accounts for impact times (x) probability of occurrence.		
AEP	Yes	The formatting is okay. We would like to see the two tables merged. Except in the extreme disturbances sections, Table 1 and Table 2 are nearly identical (the only difference is that fault types are added to Table 2). The tables could easily be merged into one, including the extreme disturbances sections to some extent.
Response: The SDT was persuaded by the commenter and others industry respondents that the two performance tables presented in Draft 2 were redundant in many areas. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance" The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed.		
NB Power Transmission	No	In the past, power systems within the NPCC Region have been designed to meet NPCC design criteria, which is basically that any design contingency does not cause instability of the NPCC defined bulk power system, and does not result in any emergency limit violations (thermal, voltage or stability), unless those violations are contained within a small local area of the system and can be mitigated. Design to NPCC criteria may include, and does include in many cases, interruption or curtailment of firm transmission service, underfrequency load shedding, undervoltage load shedding or SPS tripping of generation and/or load. The proposed table introduces new design criteria for which present power systems within NPCC are not presently designed to - being the restrictions on interruption of firm transmission service and consequential load for certain contingencies as outlined in the table, which up to this point was acceptable by NPCC design criteria, and the present NERC TPL Standard. The table should not impose new design criteria on the existing power system and should be relaxed such that present NPCC design criteria is acceptable into the future, as historically it has been proven to provide acceptable levels of reliability in the NPCC area. There would be enormous impacts on existing transmission service agreements and compliance issues if the design criteria outlined in the table is imposed. Meeting the design criteria outline in the table would require building new transmission facilities with, in some cases, very little benefit to the

Organization	Question 7:	Question 7 Comments:
		loads in terms of reliability. For example, there is an area of the system consisting predominately load. This area is supplied by two 345 kV transmission lines and three 138 kV lines. Studies show that under certain low probability, but predictable, conditions that the loss of one of the 345 kV supplies will result in unacceptable low voltage or thermal limit violations on equipment within the area. Therefore, an SPS has been utilized which trips load within the area on the loss of the 345 kV line in order to prevent unacceptable low voltage or thermal limit violations under these low probability conditions. In this case these loads are considered non-consequential and tripping them for a loss of a 345 kV line is unacceptable as per P1 in the table. Now assume that this arrangement has been in service operationally for the past 10 years and has only operated twice resulting in a 2 hour outage to these loads each time. Now also assume that these same loads have been interrupted 15 times (for a total of 30 hours) in the past 10 years because outages of a radial line within the area that these loads connected to. In this case, the loads are considered consequential and these interruptions are acceptable. Compliance with the design criteria in the table in this case would require building additional transmission into this area to prevent the load loss by SPS on the loss of the 345 kV line. Assume the cost of this new transmission is 80 million dollars and its net benefit would be to prevent (historically) 2 interruptions out of 17 total interruptions to only the loads in question within the area. The design criteria in the table in this case do not provide adequate benefit for cost for these loads in this area. Adequate transmission planning must take into account engineering judgment concerning cost/benefit ratio to loads as well as type of loads served, expectations of loads in terms of interruptions and where money can be best spent to reduce interruptions to loads. The criteria outlined in the table does not achieve this in all cases. The table should not dictate what contingencies can result in consequential load loss or interruption of firm transmission service. These decisions should be left to local planning engineers who have in-depth knowledge of local transmission issues (as well the interconnected power system)and reliability needs of loads involved. The table should only state that the listed contingencies will not result in system instability or violations of emergency thermal and voltage limits following all automatic actions. Table 1 in the existing version of the TPL Standards with its footnotes b) and C) presently allows for this and does not have criteria as stringent as the new table. The new table should not introduce new, more stringent design criteria.

Response: The NB Power Transmission company has two primary concerns within their response: 1) an inability to interrupt Firm Transmission Service and 2) the inability to shed local Load for what they deem a low probability single Contingency event involving a 345 kV line.

Regarding the Firm Transmission Service concern, the SDT has added footnotes 5 and 10 that should help alleviate the NB Power Transmission company's concerns. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained.

Footnote 5 – When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

Footnote 10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a

Organization	Question 7:	Question 7 Comments:
System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. NB Power expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that they rely on an SPS to drop local area network Load in response to some single Contingency events and that these system designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of the TPL-001-1 and most stakeholders (and the SDT) aligned with FERC's position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement. As an alternative, an entity could seek an entity variance for the situation described. The process for obtaining an entity variance is described in detail in the "NERC Standards Development Procedure" document under the subsection titled "Variances to NERC Reliability Standards" The commenter seems to be confused by the term Consequential Load Loss based on the statement "…The proposed table introduces new design criteria for which present power systems within NPCC are not presently designed to - being the restrictions on interruption of firm transmission service and consequential load for certain contingencies as outlined in the table…" The proposed standard places no restrictions on Consequential Load Loss for any of the Planning Events or Extreme Events. The as designed Protection System actions to the event always trip Consequential Load. The performance table merely clarifies if the Transmission Planner can drop any additional Firm Load (Non-Consequential Load Loss) to alleviate the event and meet performance requirements.		
Lakeland Electric	No	Separating steady-state from dynamic (stability) in the tables makes sense. Several suggestions: On page 11 move the planning events note 1 below the Planning Events title or begin note 1 with "For planning events ?" to remove confusion between planning events and extreme event requirements. Include an analysis section in the steady-state and stability requirements sections of TPL-1 that explicitly lays out the performance requirements (including the notes) - this would make the performance requirements very clear on a line item basis and the tables would become a quick reference. Special attention should be given to defined period of time between multiple events and the actions available to the operator. In table 2 (page 17) note 3 should be changed to: "Uncontrolled cascading and islanding ?" in order to be consistent with R5.4.4. " . . . If the evaluation of implementing a change . . . shall be conducted."
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages		

Organization	Question 7:	Question 7 Comments:
that the prior Table 1 and Table 2 encompassed. In the new table format, the top notes were placed under the heading of "Planning Events" as the commenter and other industry participants of suggested. It is not exactly clear what the commenter has in mind related to the "analysis section" described in the response. However, the SDT believes the new table format provides a better "at glance" view of what is needed. However, this does not negate the need to fully understand all requirements within the standard. The time period for allowable System adjustments made to avert performance requirement violations must be completed within the time duration rating and respect the ratings limit. The reference to Requirement R5.4.4 has been deleted.		
Southern Company Transmission	Yes and No	We suggest that the word "requirements" be added to the title of the tables as in Steady State Performance Requirements. We also suggest for header note 2 of Table 2 that the words be changed from "Dynamic voltages shall" to "Voltages during dynamic simulation shall"
Response: The SDT did not include the proposed use of "requirements" in the title of the performance table since they are not within the requirements section of the standard. The SDT agrees with the proposed change in note two of Table 2. The two tables have been consolidated into one table and the header note reference for this item is now note "h". **Header note 'h'**: Planning Event P0 is applicable to steady state only.		
Brazos Electric Power Cooperative, Inc.	No	Compared to the new table format, the old Categories were better. Perhaps if there is confusion with the old table or format, this should be cleaned up. We suggest the old tables remain, or combine some of the new sections to reduce the number of categories.
Response: The set of Contingencies considered are not greatly different than those in the currently approved TPL suite of standards. The SDT tried to better clarify those Contingencies that are deemed to be Planning Events, thus requiring corrective action plans, and the Extreme Events which do not require corrective action plans. Most in industry are receptive to the new Contingency.		
IESO	Yes and No	Condition (5) at the top of Table 1, and Condition (4) at the top of Table 2 are not required since they are already covered by R3.2 and R5.2, respectively. Further, Condition (6) in Table (1) and Condition (5) in Table 2 should be stipulated in R3 and R5 since these are not performance requirements, but rather the analysis (simulation) requirements.

Organization	Question 7:	Question 7 Comments:
Response: The commenter is correct that Condition 5 of the Table 1 and condition 4 of Table 2 which state "Simulate the removal of all elements that Protection Systems and controls are expected to disconnect for each event" is also within the standard's requirement language. However, the SDT has retained this information within the new performance table as it is key information repeated for clarity and convenience. In regards to the comments on condition 6 and condition 5 which refer to "normal clearing", the SDT believes that Requirements R3 and R4 which refer to the need to meet performance requirements stated within Table 1 cover the concern raised. The table note that references "simulate Normal Clearing unless otherwise specified" is now introductory note "d".		
North Carolina Electric Membership Corp	Yes and No	We would like the headings to be repeated at the head of each page. Also, enumerate Stability Tables different from the Steady State to distinguish between them.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". This changed has negated the need for the Planning Event category naming convention changes suggested by the commenter and the team retained the P1 through P7 references for Planning Events. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Therefore, the need for repeating headers on subsequent pages has been eliminated as all Planning Events are presented on a single page.		
ERCOT System Planning	No	The table is hard to read and follow since it spans multiple pages and the table headers are not repeated on each page. ERCOT believes that there are two many categories. For example, in Table 1 both Category P1 and Category P3 are not necessary. Since they require the same system performance and P3 is more severe than P1, it can be assumed that successful simulation of P3 would result in successful simulation of P1. Category P2-1 can not be simulated without modification to typical transmission models. Normal steady state power flow software typically has as a line either in or out of service, but not half in and half out. "Breaker Fault" and "Stuck Breaker" definitions are included in the table notes, but would probably be better placed with the other defined terms. It is somewhat unclear as to why there are multiple names as the steady state system impact and requirements are the same. Also, the stability impacts would be more severe for a stuck breaker assuming delayed clearing. This would allow for removal of P2-3 and P2-4 in both Tables 1 & 2. It appears that P4 and P5 are duplicating efforts as well. It is not specified which entity is responsible to define and provide contingency definitions in industry standard software format such as those requiring knowledge of protection system failures and lines on the same structure for more than 1 mile. Only entities such as TOs and GOs have access to that knowledge.

Organization	Question 7:	Question 7 Comments:

Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.

The set of Contingencies considered are not greatly different than those in the currently approved TPL suite of standards. The SDT tried to better clarify those Contingencies that are deemed to be Planning Events, thus requiring corrective action plans, and the Extreme Events which do not require corrective action plans. Most in industry are receptive to the new Contingency categorization so the TPL SDT has not altered its organization of the performance requirements. The P3 and P1 Contingency events are unique and can provide differing results since they result in unique generation dispatch. The SDT believes it is import to study both conditions.

In regards to the P2.1 event, the intent is to capture a potential condition of serving Load that is tapped from a normally networked line from a single source location in the Contingency (single ended) condition. If a line exists (breaker to breaker) that does not directly serve Load, the P2.1 condition would not apply and only the normal N-1 condition of the line would be studied. See the newly added footnote 8 that better describes the intent of the P2.1 Planning Event. The SDT believe existing transmission models will not require adjustment for the P2.1 event, however, Contingency lists run against the model may require some adjustments.

8. Inadvertent tripping of breakers on one end of a normally networked Transmission circuit such that the line is now open at that end and possibly serving Load radial from a single source point.

The stuck breaker reference remains as a footnote to the table – see footnote #11.

11. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) breaker, only one pole is assumed to remain closed. ~~The~~A stuck breaker ~~event~~ introduces a delayed clearing mode.~~ Normal Clearing is when the Protection System operates as designed and the Fault is cleared in the time normally expected with proper functioning of the installed protection systems. Breaker fail relay operation is a predetermined time that occurs after the Protection System operates and the breaker has failed. Breaker fail relaying will also isolate a predetermined portion of the electric system to isolate the failed breaker. Delayed clearing of a Fault is due to failure of any Protection System component that prevents the Protection System from operating normally.~~

The commenter is correct that some conditions such as "stuck breaker" or "internal breaker fault" would yield similar outcomes from a steady-state perspective, however, when considered from a dynamic Stability analysis each could have unique outcomes. As the commenter notes a delayed clearing mode, such as the stuck breaker analysis, would be expected to be more severe from a Stability mode. The SDT has retained P2.3 and P2.4 as they are considered single Contingency events as compared to the multiple Contingency stuck breaker event.

The P4 and P5 are unique Planning Events. The P5 Protection System failure can produce various outcomes depending on the Protection System element which failed – relay, CT, PT, battery, etc. The SDT has revised the P5 event description to remove the reference to "single component failure" and has revised the P5 event description to retain what is stated in the currently approved TPL standards under Category C6 through C9 related to the study of Protection System failures. It is left to the judgment of the Transmission Planner and the Planning Coordinator to select the appropriate review and it is expected that a worst case scenario that is something less than loss of the substation, which is considered an Extreme Event, would be evaluated. Finally, as noted in Requirement R3.4,

Organization	Question 7:	Question 7 Comments:
the Transmission Planner and Planning Coordinator is provided flexibility in selecting the more severe P5 events for study related to their system and it is not expected that every possible scenario for Protection System failure would be studied. It most cases it is unlikely that detailed system protection knowledge would be needed to develop the Contingency lists needed to perform Transmission planning studies. Ultimately it is the Transmission Planner and Planning Coordinator responsibility to ensure the simulated Contingencies accurately simulate the removal of all elements that the Protection Systems are expected to disconnect for a given event. If assistance is needed from asset owners then it is the Transmission Planner and/or Planning Coordinator's responsibility to coordinate such a review. The standard does not place requirements on the asset owners.		
Duke Energy	Yes	Separating the steady state and stability tables greatly improves and clarifies the requirements of the standard. The tables could be improved if the headings were put on each separate page. Placing headers in the requirements section of the standard would improve understanding of the flow of the document.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments to do so and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The SDT feels that with the consolidation of requirements that were made for the third posting that headings within the body of the requirements are not needed and NERC legal staff does not support the use of headings to subdivide requirements.		
Florida Reliability Coordinating Council, inc	No	The Steady State and Stability Performance Tables are very long (currently the these two table are 13 pages) and confusing. Please consider combining and condensing the two tables into one, and either add footnotes or expand the table headings to allow better understanding of the performance requirements.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Therefore, the need for repeating headers on subsequent pages has been eliminated as all Planning Events are presented on a single page.		

Organization	Question 7:	Question 7 Comments:
The SDT believes the new table format improves the readability of the expected performance requirements.		
SERC Reliability Review Subcommittee and Planning Standards Subcommittee	Yes	We recommend that the headings be repeated at the head of each page.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.		
Oncor Electric Delivery	No	In Table 1-Steady State Performance several terms more relating to system stability performance appear such as post-transient voltage, voltage instability, fault plus stuck breaker, etc. These terms would appear to be most appropriate in only Table 2-Stability Performance, where this type of analysis is performed, e.g.- placing a fault at a location based on available short circuit MVA at that point in the transmission system and then analyzing the post transient voltage and generator response.
Response: The SDT agrees that the prior draft Table 1 included some terms that were more appropriate for stability analysis references. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments to do so and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The SDT believes the new table format improves the readability of the expected performance requirements. Additionally, the SDT took great care to separate the introductory table notes for those items that apply to both steady-state and stability analysis as well as independently to one or the other.		
FirstEnergy Corp.	Yes	The overall table format is much improved over Draft 1 and it provides better alignment between the steady-state and stability tables. The SDT is encouraged to consider consolidation into one table based on the minimal differences within the two tables. FE offers the following additional comments related to the tables:TABLE 1, STEADY-STATE & TABLE 2, STABILITY: 1) Do the table notes at the top of the table only apply to the Planning Events? If so, it is suggested to move the row that says Planning Events to be positioned above the notes.

Organization	Question 7:	Question 7 Comments:
		2) Top Table Notes, Item 2 - It is our opinion that it should be based on the TPs criteria. 3) Top Table Notes, Item 3 - These should read consistent on both tables. Also, is cascading well understood and how is it tested for? 4) The use of numeric notes at both the top and bottom of the table causes confusion related to the superscript number references on various terms within the table. The superscript items appear to be footnote references to the notes area at the bottom of the table. It is suggested that the items listed at the top of the table use alpha character references to demarcate each item. 5) Remove the footnote reference to note 3 on the Header titled "Event" (column 3). The reference in column 4 is better suited and covers the intent of the note. 6) For the P3 contingencies, it is unnecessary to individually analyze all BES generation units within a footprint along with an additional contingency. The planner allowed to use reasonable judgment and run only a subset of the larger units in this scenario. For example, there would be no need to contingencies against an outage of each unit at a multi-unit plant. Checking the contingencies against the outage of the largest unit at that plant would be sufficient. 7) A header row should be repeated on each page for improved readability. TABLE 1, STEADY-STATE: 1) Extreme event descriptions, item 2e ? why is this needed? How would this occur? What would be evaluated, high voltage? Stability issues? Note that it wouldn't be stability concern - this is the steady state table. 2) Extreme event descriptions, item 3b - how is this condition any different than what is studied in extreme event item 1 (N-2, no adjustment)? We suggest that item 3b be removed. 3) Extreme event descriptions, item 3c is too vague and it is suggested that it be removed. 4) Notes section (bottom of table), item 1 - Various topics are covered within this note - stuck breaker, breaker relay failure, normal clearing, delayed clearing - it should be broken up. Why include a discussion about delayed clearing in a steady-state table? 5) Notes section (bottom of table), item 4 ? We interpret FACTS to mean Flexible AC Transmission Devices and this means different things to different companies. FACTS devices can be series devices and not necessarily shunts as referred to in the table. It is noted that there is not footnote reference pointing to item 4 within the table. TABLE 2, Stability: 1) Planning Event P1 - Indicates SLG or 3-PH, which one is needed? This should be clarified in the requirements that reference this table. The intent is likely that most planners would perform the less labor intensive 3-PH simulation and if criteria were met, then the conclusion would be that SLG is also met. However, as presently written, the "OR" could be manipulated to allow someone to meet criteria for SLG but not the 3-PH. The requirements should provide clear

Organization	Question 7:	Question 7 Comments:
		expectations in this regard. (Same comment applies to P3 and P6) 2) Planning Event P1.2 - At what position on the line is the fault to be tested? Either the table or requirements that reference this Planning Event should be clear in what is required. 3) Planning Event P1.3 ? Is the fault to be placed on the high-side or low-side of the transformer? Either the table or requirements that reference this Planning Event should be clear. 4) Planning Events P1 and P2 - Is the intent that a TP would need to run all possible P1 and P2 events in dynamic stability simulations? If not, the requirements should be worded to allow the TP some flexibility in selecting the items having the most impact. To expect all of these events to be simulated within dynamics is unrealistic and unnecessary. 5) Planning Event P2.1 ? While we agree this event is warranted in steady-state, we question the need to cover this item within stability. Wouldn't breaker action clearing a fault always produce a more severe system disturbance than an inadvertent breaker trip? 6) Extreme Events ? The reference to R5.5.4 should be R5.4.4 7) Extreme Events - Items 2, a,b,c,d - should "protection system" be capitalized as the defined term in the NERC Glossary? 8) Extreme Events - Items 2f and 2gshould be removed. It is inconceivable that the simultaneous faults described could occur. 9) Notes section (bottom of table), item 1 - Does not read consistent with Note 1 from Table 1 Steady-State. As stated above, various topics are covered within this note - stuck breaker, breaker relay failure, normal clearing, delayed clearing - it should be broken up. 10) Note number 4 from Table 1 Steady-State (item on shunt/FACTS) is missing in Table 2. The first 5 notes from Table 1 should be reflected in Table 2 with the existing Table 2 note 5 being re-numbered to item 6. 11) Table 2 Note 5.a.ii. - We question whether the number of units totaling the Contingency reserve is a good criteria. Also, with regard to the phrase "the resulting apparent impedance swings must not pass through relay characteristics that would result in the tripping of any Transmission System elements", we suggest a change to "the resulting power swing shall not cause the system to separate or form electrical islands".

Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled “Steady State and Stability Performance”. The move to a single table was based on a significant number of comments to do so and based on the SDT’s view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table.

Organization	Question 7:	Question 7 Comments:

SDT RESPONSE TO THE COMMENTS MADE THAT ARE APPLICABLE TO BOTH TABLE 1 AND TABLE 2:

1) The notes at the top of the table are intended for the Planning Events. The SDT has taken the advance offered by FE and others within industry and moved the "Planning Events" title to be positioned above the introductory notes.

2) Regarding prior Top note 2, now note "g". The SDT did not make the change recommended and believes both the Transmission Planner and Planning Coordinator criteria need to be considered and the more restrictive criteria applied if warranted. Generally, the criteria used for applicable facilities would be known and agreed upon between the Transmission Planner and Planning Coordinator, for example within an RTO environment.

3) Top Table note item 3 is now referred to as note "a". The inconsistency described by the commenter is now corrected with the single table format. Cascading is a defined term in the NERC Glossary of Terms.

4) The SDT has adjusted the top notes and refer to them with alpha character references to avoid confusion with the table footnotes that are referenced within the table.

5) The footnote reference to note 3 on the Header titled "Event" (column 3) of the prior Table version has been removed. The footnote recommended by the commenter is now used and is referenced as footnote 2 in the new table.

2. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level for stated performance criteria applies regarding allowances for interruptions of Firm Transmission Service and loss of Non-Consequential Load.

6) Contingency P3 is considered a multiple Contingency event and as described in Requirement R3.4 the Transmission Planner is expected to cover those Contingencies "… that are expected to produce more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe System results." Therefore, the SDT agrees with the commenter that the Transmission Planner would not be required to run every generation outage in combination with an addition single Contingency.

7) The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.

SDT RESPONSE TO THE COMMENTS MADE THAT ARE APPLICABLE ONLY TO TABLE 1:

1) The 2e Extreme Event came from the existing TPL standard, category D11 contingency. The SDT considers this to be more appropriate for steady state analysis than for Stability analysis and that the main intent is to guard against an extreme voltage rise.

2) The SDT agrees with FE related to Extreme Event item 3b and it has been removed in the new table.

3b. ~~Loss of two Transmission lines in different rights-of-way prior to System adjustments for conditions such as:~~

3) The SDT disagrees with the commenter that "Extreme event description item 3c is too vague and it is suggested that it be removed."

4) The SDT agrees that a variety of topics were covered in the prior footnote 1 of Table 1 and that a discussion on delayed clearing was not applicable to a steady-state table. We have revised this footnote which is now footnote 11 to focus on the stuck breaker topic. Many of the prior references in this note were

Organization	Question 7:	Question 7 Comments:

NERC Glossary of Terms definitions and have been removed.

11. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) breaker, only one pole is assumed to remain closed. ~~The~~A stuck breaker ~~event~~ introduces a delayed clearing mode.~~ Normal Clearing is when the Protection System operates as designed and the Fault is cleared in the time normally expected with proper functioning of the installed protection systems. Breaker fail relay operation is a predetermined time that occurs after the Protection System operates and the breaker has failed. Breaker fail relaying will also isolate a predetermined portion of the electric system to isolate the failed breaker. Delayed clearing of a Fault is due to failure of any Protection System component that prevents the Protection System from operating normally.~~

5) The SDT has corrected the footnote reference to FACTS to better clarify that the SDT's intent of referring to only those FACTS devices which are shunt devices. The new footnote is footnote 7 and is now referenced within the Planning Event table information.

7. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground.

SDT RESPONSE TO THE COMMENTS MADE THAT ARE APPLICABLE ONLY TO TABLE 2:

1) The confusion in Planning Event P1 – indicating a "SLG or 3-PH" has been resolved and now more clearly indicates that a 3-PH fault must be passed. The P3 and P6 Planning Events now indicate the intent is to pass a SLG event for these items. However, as stated in footnote 3, if a Stability study indicates that criteria is met for a 3-PH analysis, the results of that test are sufficient to meet the less stringent SLG criteria.

2) This is left to the judgment of the Transmission Planner and the Planning Coordinator. It is expected that you study the worst case fault location.

3) This is left to the judgment of the Transmission Planner and the Planning Coordinator. It is expected that you study the worst case fault location.

4) It is not expected that a Transmission Planner would analyze every Planning Event scenario for P1 and P2 within a Stability study. Requirement R4.5 provides the Transmission Planner the flexibility desired by FE in selecting the items having the most impact.

5) No. Sometimes opening a breaker produces a more severe dynamic voltage swing than clearing a fault at that location. A fault can stimulate machine exciters into a faster response. A slower response from exciters due to opening a breaker can result in larger dynamic voltage swings.

6) The reference to requirement R5.5.4 has been removed as some commenters felt this created a circular reference between the table and the requirement language.

7) The commenter is correct that the term "Protection System" as used in Extreme (Stability) Events items 2, a,b,c,d is a NERC defined term in the NERC Glossary of Terms and is now correctly capitalized within these Extreme Event descriptions

8) Extreme (Stability) Events items 2f and 2g have been retained by the SDT and these items are consistent with the current FERC approved TPL-004 category D6 and D7. Other commenters have not objected to these items.

9) The SDT agrees that a variety of topics were covered in the prior footnote 1 of Table 2 and that a discussion on delayed clearing was not applicable to a steady-state table. We have revised this footnote which is now footnote 11 to focus on the stuck breaker topic. Many of the prior references in this note were NERC Glossary of Terms definitions and have been removed. The prior footnote 1 inconsistencies indicated by the commenter have been resolved by moving to

Organization	Question 7:	Question 7 Comments:
the single table format. 10) The SDT agrees that there were missing footnotes in Table 2 when compared to the prior Table 1 footnotes. This is no longer an issue in the single table format as only one set of footnotes is used. 11) The SDT believes that the Contingency reserve is the appropriate maximum amount of generation which should be allowed to be lost for Planning events P2-P7. Also, the SDT believes the appropriate performance requirement for Planning Events is for no additional lines to be allowed to trip due to apparent impedance swings.		
Orlando Utiliites Commission	Yes and No	I like the concept of the new performance tables however if they could be made shorter that would be handy. I have the following specific suggestions, although they may be moot if the table is redesigned. The way the notes at the top of table 1 and table 2 are written it appears that they apply to planning single, planning multiple and extreme event sub-tables. However this is in conflict with some parts of the standard itself and the team's comments on the conference call. For example Requirement R3.3.2.2 applies facility ratings only to planning single contingencies only, so which is correct the requirement or the note that applies it to everything? I have several suggestions to fix this: 1. Move the "notes" to under the Planning Event sub table 2. Making 4 tables with the Extreme Events being a table 2 & 4 respectively 3. Indicating the notes as only applying to specific planning events. The discrepancy between requirement R3.3.2.2, the table note and comments on the conference call also needs to be corrected either by expanding the applicability of R3.3.2.2 to multiple contingencies or reducing the scope of the corresponding note. It should be clarified somewhere that the Transmission Planner and Planning Coordinator select the range of the system contingencies for N-1. Otherwise some may interpret this as only having to test contingencies on their own system (insufficient from a reliability perspective for many systems) while some auditors may interpret this as requiring every possible n-1 in the US and Canada as necessary. For example a requirement R3.2.3 could be added stating "The planning assessment should include a technical rationale for the range of transmission lines, transformers and other equipment considered". This could also be handled as a note on the tables to the effect of "The study should include a technical rationale for the range of transmission line and generators considered."
Response: The introductory notes have been moved under the "Planning Event" portion of the performance table as suggested by the commenter. The notes apply to all Planning Events – system normal (n-0), single Contingency and multiple Contingency. The commenter raises a valid point of confusion related to allowable System adjustments as Requirement R3.3.2.2 seems to imply that the System adjustments may only be applicable for single Contingency. Redispatch of generation and other System adjustments are allowed for provided that all Facilities shall be operating within their Facility Ratings. The requirement has been removed and replaced with Table 1 header note "e" since the text in the former requirement was explanatory of what was allowed and not requirement language. **e.** For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such		

Organization	Question 7:	Question 7 Comments:
adjustments are executable within the time duration applicable to the Facility Ratings. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. The list of Contingencies is expected to cover the Transmission Planner or Planning Coordinator system for which they are responsible for, including any tie-lines to adjacent Transmission systems. The standard does not preclude the Transmission Planner or Planning Coordinator to expand the list of Contingencies to include some Contingencies of interest or known impact for the adjacent System(s). It is expected that through peer reviews, the Transmission Planner or Planning Coordinator may initially learn of any new event within an adjacent System that impacts their own System.		
Entergy Services, Inc.	Yes and No	Given the type of information the SDT was trying to convey in the Tables, the format is fine. However, the enhanced standards create a conflict between the planning criteria used for evaluating transmission service (typically a standard N-1 thermal only analysis for ATC/AFC calculations) and the criteria for reliability as proposed by this standard. This disconnect will unfairly shift the cost of expanding the transmission system to the native load customers while wholesale and point-to-point transmission customers will reap the benefits of the additional capacity installed.
Response: The SDT has added footnotes 5 and 10 related to Firm Transmission Service. Footnote 5 indicates that interruption of conditional firm transfers is permitted for all Planning Events and footnote 10 indicates that interruption of Firm Transmission Service coupled with appropriate generation re-dispatch can be utilized for multiple Contingency events as a System adjustment, where indicated in Table 1 as being part of the Initial System Condition, and as a post-Contingency corrective action so long as no interruption of Non-Consequential Load occurs and all Facility Ratings are maintained. **5**. When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
BPA Transmission Reliability Program	No	We suggest that the tables for Steady State and Stability Performance could be combined into one table, for simplicity. Separate columns could be used for Steady State versus Stability performance criteria.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments to do so and based on the SDT's view that the Planning Events were the same for		

Organization	Question 7:	Question 7 Comments:
both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.		
PPL EnergyPlus	Yes	The new format is a nice improvement. On the SDT conference call, it was stated that table 1 and table 2 assume different starting points; if so, could this be spelled out in the standard? Also, consequential generation loss isn't defined.
Response: The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance". The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table. The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages. The initial system conditions are described for each of the Planning Events and are the same for both steady-state and Stability. The SDT did not feel the need to define consequential generation loss for the standard.		
PacifiCorp	Yes	We agree with the proposed format changes of the Tables.
JEA	Yes and No	JEA can live with them as is, but would also welcome enhancements. Will defer enhancements to others.
Lafayette Utilities System	Yes	
Arizona Public Service Co.	Yes	We agrees with the proposed format changes of the Tables.
LCRA TSC	Yes	
NERC and Regional Coordination	Yes	

Organization	Question 7:	Question 7 Comments:
E.ON U.S. Transmission Planning	Yes	

Response: Thank you for your response. The SDT has reformatted the performance tables (Table 1 Steady-State and Table 2 Stability) into a single table format based on commonalities between the two prior individual tables. The new Table 1 is titled "Steady State and Stability Performance".

The move to a single table was based on a significant number of comments and based on the SDT's view that the Planning Events were the same for both Steady-State and Stability. For Extreme Events, the separation of Steady-State and Stability that many in industry seem to prefer for the two table format has been retained in the new table.

The new single performance table is greatly condensed from the Draft 2 version and the entire body of material is now contained on three pages compared to the thirteen pages that the prior Table 1 and Table 2 encompassed. Headers are repeated on subsequent pages.

8. A new definition for "Bus-Tie Breaker" was added to clarify the type of substation design and breaker position that qualify as a Bus-tie Breaker. Do you agree with the proposed definition? If not, please explain.

Summary Consideration:

Based on the comments received from the industry, the SDT has revised the definition of Bus-tie Breaker.

Bus-tie Breaker: A circuit breaker that is positioned to connect two individual ~~straight bus~~ substation bus configurations. ~~(Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers.)~~.

Organization	Question 8:	Question 8 Comments:
NPCC	No	The definition provided is too limiting. It says that if you have two rings with a bus tie breaker in between, it is no longer a bus tie breaker. NPCC Participating Members Recommend, "A circuit breaker that is positioned to connect two individual station configurations." We do not agree that, "(Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers.)", as we have examples where stations of this nature are connected through a single "bus-tie breaker".
TVA System Planning	Yes	TVA does appreciate this clarification, but suggests the following wording: "A circuit breaker that is positioned to connect two individual straight bus substation configurations that if faulted results in both bus sections being cleared."
Omaha Public Power District	No	The term "straight bus" is not an industry-standard term. Replace "straight bus" by "single-bus, single-breaker".
Progress Energy Carolinas		The use of the word "straight" in the definition raised questions. We recommend the word straight be removed or change the definition to the following. "Bus-tie Breaker: A circuit breaker positioned to connect two individual buses with one or more other breaker positions on each bus. (Substation configurations such as a ring-bus, breaker-and-a-half, or double-breaker do not generally include bus-tie breakers.)"
Platte River Power Authority	Yes and No	Delete the sentence in parentheses.
BCTC	No	Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. What would these breakers be called? We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.

Organization	Question 8:	Question 8 Comments:
Manitoba Hydro	Yes	The Bus-tie Breaker definition provides the clarification Manitoba Hydro requested in our draft 1 comments. However, we suggest the wording in brackets should be deleted as it is possible to add bus-tie breakers to schemes like the breaker-and-a-third bus in large stations.
Transmission Agency of Northern California	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
National Grid	No	The definition provided is too limiting. It says that if you have a two rings with a bus tie breaker in between, it is no longer a bus tie breaker. We recommend modifying the definition to read, "A circuit breaker that is positioned to connect two individual station configurations. We do not agree that, "(Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers.)", as we have examples where stations of this nature are connected through a single "bus-tie breaker".
OPUC	Yes and No	A better definition of Bus-Tie Breaker might be: “A circuit breaker that divides a bus section with multiple tap off points into two bus sections.”
Pacific Gas and Electric Co.	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Public Service Company of New Mexico	No	We do not disagree with the proposed definition change. However, we do not agree that “Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Puget Sound Energy, Inc.	No	We do not disagree with the proposed definition change. However, we do not agree that “Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two

Organization	Question 8:	Question 8 Comments:
		bus sections.
Idaho Power Company	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
SMUD	No	We do not disagree with the proposed definition change. However, we do not agree that "Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Hydro-Qu?bec Trans?nergie (HQT)	No	? The definition provided is too limiting. It says that if you have a two rings with a bus tie breaker in between, it is no longer a bus tie breaker. HQT recommend, "A circuit breaker that is positioned to connect two individual station configurations. We do not agree that, "(Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers.)", as we have examples where stations of this nature are connected through a single "bus-tie breaker".
Sierra Pacific Power Comapny / Nevada Power Company	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Ameren	No	To provide clarity, a revised definition is proposed. "A bus-tie breaker is a circuit breaker that connects two individual bus sections with one or more breaker positions on each bus; substation configurations such as ring-bus, breaker-and-a-half, or double bus-double-breaker do not have bus-tie circuit breakers."
SRP	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.

Organization	Question 8:	Question 8 Comments:
MidAmerican Energy Company	No	MEC suggests applying the proposed definition to a new term, "Straight Bus-Tie Breaker". The creation of a narrow, special application definition of "bus tie breaker" is generally confusing and misleading. The term "bus tie breakers" is widely used in the industry in the context of various bus configurations. In addition, this narrow definition may create confusion if other Standards refer to bus-tie breaker in a different context.
Tucson Electric Power Company	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
SERC Dynamics Review Subcommittee	No	The use of the word ?straight? in the definition raised questions. We recommend the word straight be removed or change the definition to the suggestion below: Suggestion: Bus-tie breakers are defined as a circuit breaker position that connects two individual buses with one or more breaker positions on each bus.
MRO NERC Standards Review Subcommittee	No	The MRO suggests applying the proposed definition to a new term, "Straight Bus-Tie Breaker". The creation of a narrow, special application definition of "bus tie breaker" is generally confusing and misleading. The term "bus tie breakers" is widely used in the industry in the context of various bus configurations. In addition, this narrow definition may create confusion if other Standards refer to bus-tie breaker in a different context.
Modesto Irrigation District	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Tri-State G&T	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Brazos Electric Power Cooperative,	No	Part of the definition of a bus tie breaker as outlined in this Standard should be that it is the ONLY connection between 2 substation buses. Not sure why the word 'straight' is used in this definition. If a bus with a 90 degree turn is connected to another bus by a single tie breaker, does this not apply? Also, breaker and a half schemes do

Organization	Question 8:	Question 8 Comments:
Inc.		sometimes have a bus tie breaker in them although its probably not common. Including those specifics in not needed.
ColumbiaGrid	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Southern California Edison	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two bus sections.
Northeast Utilities	No	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.
North Carolina Electric Membership Corp	No	To provide clarity, a revised definition is proposed. A bus-tie breaker is a circuit breaker that connects two individual bus sections in a straight bus substation configuration. Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double-breaker do not have bus-tie circuit breakers.
American Transmission Company	No	We suggest applying the proposed definition to a new term, "Straight Bus-Tie Breaker". The creation of a narrow, special application definition of "bus tie breaker" is generally confusing and misleading. The term "bus tie breakers" is widely used in the industry in the context of various bus configurations. In addition, this narrow definition may create confusion if other Standards refer to bus-tie breaker in a different context.
Duke Energy	No	The use of the word ?straight? in the definition raised questions and did not seem crucial to the definition. We recommend the word ?straight? be removed from the definition.
Central Maine Power Company	No	The definition provided is too limiting. It indicates that if a substation has two rings with a bus tie breaker in between, that breaker is no longer a bus tie breaker. Recommend instead, "A circuit breaker that is positioned to connect two individual station configurations. The breakers in a bus scheme are not bus tie breakers but the breakers that tie bus schemes together are bus-tie breakers."
NSTAR Electric	No	The definition provided is too limiting and should be changed to "A circuit breaker that is positioned to connect two individual station configurations. The breakers in a bus scheme are not bus tie breakers but the breakers that tie bus

Organization	Question 8:	Question 8 Comments:
		schemes together are bus-tie breakers."
New York Independent System Operator	No	The definition provided is too limiting. It says that if you have a two rings with a bus tie breaker in between, it is no longer a bus tie breaker. Recommend, "A circuit breaker that is positioned to connect two individual station configurations. We do not agree that, "(Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers.)", as we have examples where stations of this nature are connected through a single "bus-tie breaker".
SERC Reliability Review Subcommittee and Planning Standards Subcommittee	No	To provide clarity, a revised definition is proposed. A bus-tie breaker is a circuit breaker that connects two individual bus sections in a straight bus substation configuration. Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double-breaker do not have bus-tie circuit breakers.
Alberta Electric System Operator	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a-half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: "A circuit breaker that's only protective purpose is to isolate a segment of a bus."
ISO New England Inc.	No	he definition provided is too limiting. It says that if you have two rings with a bus tie breaker in between, it is no longer a bus tie breaker. Recommend, "A circuit breaker that is positioned to connect two individual station configurations. The breakers in a bus scheme are not bus tie breakers but the breakers that tie bus schemes together are bus-tie breakers."
Orlando Utiliites Commission	Yes and No	I neither for or against breaking out these breakers as a separate class. However a graphic or sketch of some example an easier concept to understand both in terms of what it is and why it is worthy of special attention.
Entergy Services, Inc.	No	Change term from ?Bus-tie Breaker? to ?Straight Bus Substation Bus-tie Breaker? with the following definition: A bus-tie breaker is a circuit breaker that connects two individual bus sections in a straight bus substation configuration. References to Bus-tie Breaker in the standard would also need to be changed accordingly.
US Bureau of Reclamation	No	We do not disagree with the proposed definition change. However, we do not agree that ?Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers. Some breaker-and-a half and double-breaker layouts may have bus breakers located mid-way in the side elements. We propose the following definition: A circuit breaker that divides a bus section with multiple tap off points into two

Organization	Question 8:	Question 8 Comments:
		bus sections.
BPA Transmission Reliability Program	No	The term "Bus Tie" implies tying any two buses together. However, the intent of this standard is actually referring to connecting the main buses of two adjacent main and auxiliary configured substations together. Therefore, we recommend changing the term "Bus Tie Breaker" to "Bus Sectionalizing Breaker". We also recommend removing the parentheses portion of the Bus Tie Breaker definition. It does not provide clarification and may not apply to all utilities' systems.
Response: The SDT has revised the definition as follows: **Bus-tie Breaker**: A circuit breaker that is positioned to connect two individual ~~straight bus~~ substation bus configurations. ~~(Substation configurations such as ring-bus, breaker-and-a-half, or double bus-double breaker protection schemes do not use bus-tie breakers.)~~		
Progress Energy Florida, Inc.	No	PEF understands the intent behind the wording of the definition, but neither agrees with the definition nor its use in various applications in the Standard. Bus tie breakers as defined in the draft Standard are limited to connecting two straight bus configurations. In reality, the term bus-tie breaker can be, and is used for other applications. PEF suggests that the SDT further research the use of this term in the industry. But more to the point, PEF does not see the need for a distinction between bus tie and non bus tie breakers and ultimately recommends that this be removed from the Standard.
Florida Power and Light	No	Bus tie breakers are defined exclusively to straight bus configurations. They can be used for other breaker configurations. We do not see the need for a distinction between bus tie and non bus tie breakers.
Response: The SDT notes that a number of commenters disagreed with the definition. However, the number who indicate that the distinction should be eliminated is in the minority. Therefore, the SDT has retained the distinction while having made changes to provide a simpler and broader definition of bus-tie breaker.		
Dominion - Electric Transmission Planning	Yes	
City Water, Light & Power - Springfield, Illinois	Yes

FirstEnergy Corp.	Yes	
Response: The SDT thanks you for your response but the majority of commenters expressed a desire to change the definition.		

9. Some commenters questioned why a Bus-tie Breaker would have a different performance requirement than a non-Bus-tie Breaker, stating that all breakers have the same probability for failure. It may be true that generally the probability for failure of any given breaker would not vary substantially among similar types of breakers, but the Bus-tie Breaker reduces exposure and consequences of bus faults. The different performance expectations in Tables 1 and 2 are based on promoting a higher level of reliability for the Transmission Systems operated above 300 kV.

It is recognized by the SDT that a straight bus design has some undesirable exposure to bus faults, but that Bus-tie Breakers can be utilized to improve reliability for bus faults and problems associated with exit breakers. As a result, the risk of an internal breaker fault was deemed to be significantly less than the benefit that is gained by reducing the exposure to a total bus failure. Therefore, provisions were built into the performance requirements that would not discourage their use.

Do you agree that non-Bus-tie Breakers rated above 300 kV should have more stringent performance requirements than Bus-tie Breakers? If not, please explain why and/or suggest specific changes.

Summary Consideration:

While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.

A number of commenters raised concerns with the less stringent requirement for DC systems. The SDT has removed the less stringent requirements for DC lines in the Table.

Due to industry comments, the SDT has changed/added the following:

Footnote 5 - When the conditions and/or event(s) being studied form the basis for conditional firm transmission service, curtailment of that conditional firm transmission service is allowed

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled ‘Initial System Conditions’) and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner’s planning region are relied upon, Facility Ratings in those regions must be considered.

Consequential Load Loss: ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load’s response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load’s response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed, Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions.

Non-Consequential Load Loss: Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~

Load Reduction: Load that is still connected to the System, but is reduced due to lower voltage conditions following a Planning or Extreme Event.

Supplemental Load Loss: Load that is disconnected from the network by end-user equipment responding to post-Contingency System conditions.

Organization	Question 9:	Question 9 Comments:
TVA System Planning	No	Since an internal fault on any breaker is a low probability event, we believe that Non-consequential Load Loss should be allowed.
Alberta Electric System Operator	No	We believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class.
Response: While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.		
BCTC	Yes	BCTC agrees with different performance levels. However, we have a different rationale. Our reasoning is that a bus fault has a lower probability than a line fault. Bus tie breakers are called on to interrupt faults less often than line breakers. The failure probably may be the same but the frequency of failure is lower (because they are not called on to operate as often). The explanation given above by the SDT appears to be more related to a WECC issue that bus breaker failure should be Category D.
Response: Thank you for your support of the SDT's position.		
Platte River Power Authority	No	I think the performance for non-bus-tie breakers should be the same for all BES voltages for the same reason I agree with the performance of P2.4 Internal Breaker Fault (bus tie) and P4.6 Stuck Breaker where the Stuck Breaker could be a bus-tie or "sectionalizing" breaker.

Organization	Question 9:	Question 9 Comments:
Manitoba Hydro	No	Based on industry outage statistics, event P4, the non-bus tie breaker failure has a lower probability of occurrence than event P7, the common structure event. Consequently, Manitoba Hydro recommends that the performance requirement for >300 kV should be the same as P7. Imposing a higher performance expectation on the >300 kV facilities will require significant bus reconfiguration costs to ensure compliance for existing stations. The additional cost can not be justified by the reliability gain given the low probability of the event.
Transmission Agency of Northern California	Yes and No	We interpret ?exit breakers? to mean a breaker on an element that comes in from outside the substation. We agree with applying less stringent performance requirements to bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes.
Pacific Gas and Electric Co.	Yes and No	We interpret “exit breakers” to mean a breaker on an element that comes in from outside the substation. We agree with applying less stringent performance requirements to bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes
Public Service Company of New Mexico	Yes and No	We interpret “exit breakers” to mean a breaker on an element that comes in from outside the substation. We agree with applying less stringent performance requirements to bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes.
PacifiCorp	No	We do not agree with the rationale for the requiring more stringent performance requirement levels for non-bus tie breakers above 300 kV. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes.
Idaho Power Company	Yes and No	We interpret ?exit breakers? to mean a breaker on an element that comes in from outside the substation. We agree with the rationale for the requiring more stringent performance requirement levels for non-bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes

Organization	Question 9:	Question 9 Comments:
SMUD	Yes and No	We interpret ?exit breakers? to mean a breaker on an element that comes in from outside the substation. We agree with applying less stringent performance requirements to bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes
Sierra Pacific Power Company / Nevada Power Company	Yes	We interpret ?exit breakers? to mean a breaker on an element that comes in from outside the substation. We agree with the rationale for the requiring more stringent performance requirement levels for non-bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. <table>
<tr><th>Organization</th><th>Question 9:</th><th>Question 9 Comments:</th></tr>
<tr><td></td><td></td><td>different for different voltage classes</td></tr>
<tr><td>American Transmission Company</td><td>No</td><td>We recognize that the addition of this requirement is an attempt top raise the bar above the existing standards. However, the more stringent non-bus-tie performance criteria should only be adopted if there is sufficient evidence to demonstrate the expected reliability risk (i.e. system impact x probability of occurance) is high enough to warrant the cost of the system modifications that would be needed to meet the criteria. System modifications that involve the installation of line and substation facilities >300 kV will likely take years and cost tens to hundreds of millions to build. It would be helpful to have a reliability risk analysis that justifies the application of this performance criteria before it is adopted.</td></tr>
<tr><td>Entergy Services, Inc.</td><td>No</td><td>The probability of an EHV breaker failure is extremely low. Statistically, the probability of an internal breaker failure on any given day in our system is approximately 1 failure every 10,000 days. The probability of a stuck EHV breaker in our system is approximately 1 failure every 21,000 days. While the impact of such events can be severe, the significant cost to remedy such low probability events seems unlikely to pass any reasonable cost/benefit analysis.</td></tr>
<tr><td>US Bureau of Reclamation</td><td>No</td><td>We interpret “exit breakers” to mean a breaker on an element that come in from outside the substation. We agree with applying less stringent performance requirements to bus tie breakers above 300 kV. Further, we believe that Non-Consequential Load Loss should be allowed for loss of either Bus-Tie or Non-Bus-Tie Breakers regardless of voltage class. The SDT has not presented evidence that the probabilities of failure for breakers within the same substation are significantly different for different voltage classes</td></tr>
<tr><td colspan="3">Response: The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.</td></tr>
<tr><td>Los Angeles Department of Water and Power</td><td>No</td><td>The arbitrary separation based on voltage class is discriminatory and without any scientific or historical basis. The probability of breaker failure do not increase with voltage class. In fact, breaker failures are seldom heard of at above the 300kV classes. Most breaker failures occur in lower voltage classes such as 230kv, 115kv, etc. where the short circuit current tends to be higher and thus stressing breaker contacts more severely giving rise to breaker failures. Delete any separation of voltage classes.</td></tr>
<tr><td colspan="3">Response: The SDT believes that the separation for a more stringent requirement at above 300 kV is not “arbitrary”. The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems</td></tr>

Organization	Question 9:	Question 9 Comments:
operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. The SDT believes that the separation above 300 kV is not "discriminatory" in that the standard is intended to be in place for all operators, owners, and users of the Transmission System. Finally, the SDT believes that there is scientific and historical basis in the sense that our representation of the differences between Systems above 300 kV as opposed to below 300 kV are a reasonable review of the uses of the NERC-wide Transmission System including scientific and historical considerations. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.		
National Grid	No	They should have the same performance requirements, however we understand that it is better to encourage bus-tie breakers in some applications than to hold them to the higher standard. Future station designs that need this differential treatment should be discouraged.
Central Maine Power Company	No	They should have the same performance requirements, however we understand that it is better to encourage bus-tie breakers in some applications than to hold them to the higher standard. Future station designs that need this differential treatment should be discouraged.
NSTAR Electric	No	They should have the same performance requirements. The performance standards should not encourage differential treatment for the same equipment.
FirstEnergy Corp.	Yes and No	Fundamentally, from a purest perspective, we believe that all breakers should be treated as having the same probability of failure. However, we understand the SDT's intent and agree to the higher performance expectations for the above 300kV transmission system. We also agree that without the exception provided for bus-tie breakers, some entities may take the approach to simply operate their bus-tie breakers open in order to meet the performance requirements, which would be counterproductive to the improved reliability sought by the team. The alternative would be back to back bus-tie breaker installations which may not even be feasible due to space limitations. On a going forward basis, future station designs at this voltage level should avoid straight bus designs.
ISO New England Inc.	No	They should have the same performance requirements, however we understand that it is better to encourage bus-tie breakers in some applications than to hold them to the higher standard. Future station designs that need this differential treatment should be discouraged.

Organization	Question 9:	Question 9 Comments:
Northeast Utilities	Yes	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.
Response: The SDT understands your comment as being supportive of the more stringent requirement for non-Bus-tie Breakers above 300 kV and of a more stringent requirement for Bus-tie Breakers above 300 kV in new substations. While there are a significant number of parties that commented negatively about the higher system performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the industry has indicated support for the higher performance requirement for non-Bus-tie Breakers above 300 kV and for a lower performance requirement for Bus-tie Breakers above 300 kV. Therefore, the SDT has not altered the higher system performance requirement for loss of non-Bus-tie Breakers above 300 kV and has not raised the system performance requirement for loss of Bus-tie Breakers above 300 kV for new substations.		
Tenaska, Inc.	Yes and No	Voltage is a questionable criteria for determining whether a breaker's performance requirements should be different. May want to consider a lower voltage cutoff (below 100 or below 200) as lower performance MAY have less of an impact.
Response: The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV and has not raised the system performance requirement for loss of breakers at lower voltages.		
Gainesville Regional Utilities	Yes	Our control area operates at 138 kV. Does everyone think that holding the owners of above 300 kV operating voltage systems to a higher standard really increases the total BES reliability? Does giving the DC systems a pass on some of the requirements really make sense in the world of reliability?
Response: The SDT believes that holding the owners of above 300 kV operating voltage systems to a higher standard increases the total BES reliability. The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV. A number of commenters raised concerns with the less stringent requirement for DC systems. The SDT has removed the less stringent requirements for DC lines.		

Organization	Question 9:	Question 9 Comments:
Progress Energy Florida, Inc.	No	PEF is opposed to distinction between non-Bus-tie breakers and Bus-tie breakers, and furthermore is opposed to the more stringent requirements for both in facilities above 300 kV. One primary reason has already been acknowledged by the SDT, that breakers have the same failure rate no matter the configuration in which they are placed. PEF can see two potential outcomes to the missteps being made regarding the breaker distinction: a) multiple redundancy of breakers for both Bus-tie and non-Bus-tie breaker schemes, which will require tearing down many Substations, acquiring additional property in many cases, and completely rebuilding the Substations to allow room for redundancy of breakers in series with one another; b) choosing to remove existing breakers for which a scenario of non-compliance is imminent, which could potentially pose a reliability risk to the system and possibly result in heightened risk for other Event categories.
Response: The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. Cost estimates were requested in other questions and were utilized by the SDT in determining a balance between such costs and reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV. The SDT understands your argument about discouraging the use of breakers with a higher breaker failure performance requirement. However, the SDT notes that the Transmission Planner has always needed to plan for breaker failure since it is an event that does occur. Any reliability risk that is created by taking a breaker out of service to respond to this new higher performance requirement should be covered by the responsible entity by conducting system analysis using the new standard. If the reliability risk created by eliminating a breaker results in a failure to meet the performance requirements as outlined in the new standard, then the responsible entity will be required to develop Corrective Action Plans to mitigate the risk.		
Lafayette Utilities System	No	See paragraph (b) in response to Question 15.
Response: Lafayette Utilities System indicated in paragraph b in response to Question 15 that “Adopting less stringent performance requirements for loss of elements below 300 kV may be discriminatory.” Lafayette Utilities System further indicated that this may be because more wholesale customer Load may be served at these lower voltages than Transmission Owner Load. The SDT believes that the separation above 300 kV is not “discriminatory” in that the standard is intended to be in place for all operators, owners, and users of the Transmission System. Further, the SDT disagrees with the notion that it may be discriminatory in that more wholesale Load is served from under 300 kV than the Transmission Owner’s Load. As indicated in the SDT’s responses to the comments of others, the SDT believes that systems operating above 300 kV generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers.		

Organization	Question 9:	Question 9 Comments:
Ameren	Yes and No	Yes: The installation of bus-tie circuit breakers in a straight bus configuration would reduce exposure to a) bus faults or to b) line faults with breaker failure without adding much risk for internal fault in the bus-tie breaker. Those entities that employ a straight bus substation design with bus-tie breakers have recognized that failure of the bus-tie breaker, a very low probability event, would result in the loss of multiple transmission elements and perhaps firm load for a short time until the bus sections can be restored, but bus-tie breakers are an investment worth the risk. Therefore, it is generally agreed that the outage of non-bus-tie circuit breakers should have higher performance requirements than the outage of bus-tie circuit breakers. The SDT should be commended for this change since the previous draft version. No: However, it is not clear that adopting a higher standard of performance for planning events involving transmission facilities 345 kV and above will improve overall system reliability. Some areas of the continent already have n-2 planning criteria, yet these systems have still experienced significant outages including blackouts. It is suggested that a review of the Transmission Availability Data System (TADS) data, when available, should be conducted to help assess what system performance requirements need to be strengthened before arbitrarily determining to "raise the bar" for certain voltage levels and system designs. The industry should not be forced to invest a great deal of capital to meet a new standard requirement when it would not have an immediate impact on system reliability. Some sort of cost/benefit analysis should be performed to justify any change from the present TPL-001 through 004 standard requirements. On the Ameren system, there is no indication that transmission system reliability has been degraded through the use of straight bus configurations. Also, further clarification is required to explain how to drop consequential load without cutting firm transmission service to those affected/outaged customers, and this needs to be added to the notes in Tables 1 and 2.
North Carolina Electric Membership Corp	Yes and No	The installation of bus-tie circuit breakers in a straight bus configuration would reduce exposure to a) bus faults or to b) line faults with breaker failure without adding much risk for internal fault in the bus-tie breaker. Those entities that employ a straight bus substation design with bus-tie breakers have recognized that failure of the bus-tie breaker, a very low probability event, would result in the loss of multiple transmission elements and perhaps firm load for a short time until the bus sections can be restored, but bus-tie breakers are an investment worth the risk. Therefore, it is generally agreed that the outage of non-bus-tie circuit breakers should have higher performance requirements than the outage of bus-tie circuit breakers. The SDT should be commended for this change since the previous draft version. However, it is not clear that adopting a higher standard of performance for planning events involving transmission facilities 345 kV and above will improve overall system reliability. Some areas of the continent already have n-2 planning criteria, yet these systems have still experienced significant outages including blackouts. The industry should not be forced to invest a great deal of capital to meet a new standard requirement when it would not have an immediate impact on system reliability. Some sort of cost/benefit analysis should be performed to

Organization	Question 9:	Question 9 Comments:
		justify any change from the present TPL-001 through 004 standard requirements. Also, further clarification is required to explain how to drop consequential load without cutting firm transmission service to those affected/outaged customers, and this needs to be added to the notes in Tables 1 and 2.
SERC Reliability Review Subcommittee and Planning Standards Subcommittee	No	The installation of bus-tie circuit breakers in a straight bus configuration would reduce exposure to a) bus faults or to b) line faults with breaker failure without adding much risk for internal fault in the bus-tie breaker. Those entities that employ a straight bus substation design with bus-tie breakers have recognized that failure of the bus-tie breaker, a very low probability event, would result in the loss of multiple transmission elements and perhaps firm load for a short time until the bus sections can be restored, but bus-tie breakers are an investment worth the risk. Therefore, it is generally agreed that the outage of non-bus-tie circuit breakers should have higher performance requirements than the outage of bus-tie circuit breakers. The SDT should be commended for this change since the previous draft version. However, it is not clear that adopting a higher standard of performance for planning events involving transmission facilities 345 kV and above will improve overall system reliability. Some areas of the continent already have n-2 planning criteria, yet these systems have still experienced significant outages including blackouts. It is suggested that a review of the Transmission Availability Data System (TADS) data, when available, should be conducted to help assess what system performance requirements need to be strengthened before arbitrarily determining to "raise the bar" for certain voltage levels and system designs. The industry should not be forced to invest a great deal of capital to meet a new standard requirement when it would not have an immediate impact on system reliability. Some sort of cost/benefit analysis should be performed to justify any change from the present TPL-001 through 004 standard requirements. Also, further clarification is required to explain how to drop consequential load without cutting firm transmission service to those affected/outaged customers, and this needs to be added to the notes in Tables 1 and 2.

Response: The SDT thanks you for your support with regard to the reason for a less stringent requirement for Bus-tie breakers**.** The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. Cost estimates were requested in other questions and were utilized by the SDT in determining a balance between such costs and reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.

The SDT understands your issue with regard to explaining the dropping of consequential Load without cutting Firm Transmission Service to those affected/outaged customers. The SDT has made changes to footnotes 5 and 10 in the table and revised the definition of Consequential Load Loss and Non-Consequential Load Loss to clarify the issue.

Footnote 5 - When the conditions and/or event(s) being studied form the basis for conditional firm transmission service, curtailment of that conditional firm

Organization	Question 9:	Question 9 Comments:
transmission service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. **Consequential Load Loss:** ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed, Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions. **Non-Consequential Load Loss:** Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~ **Load Reduction:** Load that is still connected to the System, but is reduced due to lower voltage conditions following a Planning or Extreme Event. **Supplemental Load Loss:** Load that is disconnected from the network by end-user equipment responding to post-Contingency System conditions.		
Florida Power and Light	No	These provisions made to not discourage the use of bus tie breakers will also not discourage the use of the single breaker/single bus substation arrangement which can have very severe consequence when used on critical BES substations. The TPL-001-1 draft also sets a threshold of higher performance to facilities above 300 kV than previously established in the existing standard. We do not agree that such a threshold is necessary or warranted. Requirements which are more stringent for these facilities may wrongly influence decisions on project alternatives in favor of facilities with less stringent requirements. Related to the more stringent requirements for facilities above 300 kV, FPL also disagrees with the performance requirements contemplated by the proposed draft standard for DC lines. The SDT stated performance requirements for DC lines as currently drafted, is discriminatory as compared to AC line performance, and needs to be addressed. This could be viewed as an exemption for DC lines and violates FERC's comparability principle as it relates to reliability performance. The TPL-001-1 draft sets a lower performance requirement for the loss of a single pole of a DC line than in the existing standard by allowing interruption of firm transfer if the transfer is deemed to be dependent on the outaged line. Firm transfers are also dependent upon AC lines. The proposed standard does not distinguish between asynchronous DC ties and the more common parallel connected DC tie. With an asynchronous DC tie, the transfer is lost with the tie, which is analogous to Consequential Load Loss which is already allowed. With a parallel DC

Organization	Question 9:	Question 9 Comments:
		tie, the transfer will be shifted to the parallel AC system and should have the same performance requirements. We do not agree that such an exception for DC lines is necessary or warranted. The decision in selecting DC vs. AC in transmission lines has traditionally been based on the break-even cost and performance of the two alternatives. The lower performance requirement may wrongly influence decisions on project alternatives in favor of DC facilities because of the less stringent reliability performance requirements.
Response: The SDT understands that the standard as drafted does not discourage the use of straight bus arrangements below 300 kV by allowing interruption of Firm Transmission Service and Non-Consequential Load Loss for all P4 events below 300 kV. The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV. A number of commenters raised concerns with the less stringent requirement for DC systems. The SDT has removed the less stringent requirements for DC lines.		
Tri-State Generatino and Transmission Association, Inc.	No	Performance requirements should depend on the potential loss of load impact of a breaker failure, not the voltage level.
Response: The SDT believes that while theoretically there would be potential merit in a loss of load impact approach to performance requirements for breaker failure; it would result in performance requirements that would be difficult to enforce. For example, such an approach would require completing estimates of the loss of Load for Contingencies for various conditions and then documenting it. The auditor would need to review these estimates as well as the documentation to become convinced that the correct performance requirement was used for each breaker. This review would need to be in addition to any other activity performed by the auditor to ensure compliance with the standard. The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.		

Organization	Question 9:	Question 9 Comments:
Brazos Electric Power Cooperative, Inc.	Yes	Yes but this seems to add another category of items to provide for in the assessment.
Response: Thank you for your support.		
IESO	No	We hold the view that all breakers can be exposed to the same types of event, i.e., they can have internal faults and can be "stuck" when attempting to open as instructed. As such, there should not be any difference in the expected system performance among them in response to system events, and regardless of the voltage levels. We suggest the SDT to revised Tables 1 and 2 such that their expected performance are identical.
Response: The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV.		
Duke Energy	No	In Table 1, Category P4, Events 1 through 5 addressing a stuck non-bus tie breaker >300kV should allow Interruption of Firm Transmission Service and Non-Consequential Load Loss, because P4 addresses a multiple contingency.
Response: The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. While a significant number of parties commented negatively about the higher performance requirement for non-Bus-tie Breakers above 300 kV, higher performance requirements are encouraged by FERC Order No. 693 and the majority of the industry has indicated support for the higher performance requirement. Therefore, the SDT has kept the higher performance requirement for non-Bus-tie Breakers above 300 kV. The SDT recognizes that Duke Energy has indirectly brought up the issue as to how the interruption of Firm Transmission Service relates to the dropping of Load in its comment. The SDT has made changes to footnotes 5 and 10 in the table and revised the definition of Consequential Load Loss and Non-Consequential Load Loss to clarify the issue. **Footnote 5 -** When the conditions and/or event(s) being studied form the basis for conditional firm transmission service, curtailment of that conditional firm		

Organization	Question 9:	Question 9 Comments:
transmission service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. **Consequential Load Loss:** ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed, Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions. **Non-Consequential Load Loss:** Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~ **Load Reduction:** Load that is still connected to the System, but is reduced due to lower voltage conditions following a Planning or Extreme Event. **Supplemental Load Loss:** Load that is disconnected from the network by end-user equipment responding to post-Contingency System conditions.		
Orlando Utilities Commission	Yes and No	If they are going to be two classes of equipment with an arbitrary cut off 300 kV is a good cutoff. However I would prefer to see the decision on what is "super BES" and regular "BES" less arbitrary and more reliability driven, such as letting the regions define this cut off just as they define BES in a manner suitable to the design of their regional system.
Response: The SDT believes that the separation for a more stringent requirement above 300 kV is not "arbitrary". The SDT feels the 300 kV and higher systems generally represent an extra-high-voltage (EHV) range that is considered the backbone of many systems in the various Interconnections. Systems operated at this range generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers which then deliver the power among other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. The SDT is preparing a NERC-wide standard for which a region can submit a regional difference that is justified based upon physical differences in that region and/or to result in a regional difference that is a higher performance requirement than the NERC-wide standard. Therefore, if a region has good cause for a different "cutoff", then the region can submit a regional difference through the NERC standards development process. This regional difference could even be submitted as part of this standards writing effort. However, it should be noted that once the regional difference is approved through the NERC standards development process, then it will be submitted to FERC and other regulatory authorities for approval. While there are a significant number of parties that commented negatively about the higher system performance requirement for non-Bus-tie Breakers above 300		

Organization	Question 9:	Question 9 Comments:
kV, higher performance requirements are encouraged by FERC Order No. 693 and the industry has indicated support for the higher performance requirement. Therefore, the SDT has not altered the higher system performance requirement for loss of non-Bus-tie Breakers above 300 kV.		
BPA Transmission Reliability Program	Yes	In general, performance requirements should be more stringent for higher voltage systems. Therefore, we agree that non-bus-tie breakers above 300 kV should have more stringent requirements.
Dominion - Electric Transmission Planning	Yes	
NPCC	Yes	
City Water, Light & Power - Springfield, Illinois	Yes

10. **The SDT made modifications in this second draft to the requirements relating to sensitivity cases. Do you concur with the modifications reflected in Requirements R2.1.3 and 2.1.4? If not, please state why and/or suggest specific changes.**

Summary Consideration:

A number of commenters agreed with the concept of the sensitivity analysis but were concerned that there is a conflict with sensitivities already included in base studies, sensitivity details, explaining why sensitivities were not run and how they affected Corrective Actions. The SDT has made the following changes:

1 – Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required year for steady state and Stability. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances.

The revision also includes the removal of the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. Since these are sensitivities, any and all variances provide some level of information as to how the System responds to such variances.

2 – The sensitivities listed in Requirement R2.1.3 were revised for clarity; however, the SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies.

3 – Requirements R2.1.4 and R2.4.4 that require explanation of performing additional sensitivities that are not listed in Requirement R2.1.3 have been deleted.

4 – Requirement R2.6 has been revised for clarity. The entity can use any sensitivity studies it has performed in conjunction with the required current and past studies to develop its Corrective Action Plan.

The following requirements were changed due to industry comments:

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable.

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.7 (now R2.6) For Planning Events shown in Table 1 ~~– Steady State Performance and Table 2 – Stability Performance~~, when the analysis indicates an inability of the System to meet the performance requirements in the tables, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall:

Organization	Question 10:	Question 10 Comments:
Dominion - Electric Transmission Planning	No	We are of the opinion that the proof of a negative that is required for sensitivity cases (i.e. - that the sensitivity cases were more severe for those selected conditions vs. those not tested) is burdensome. The burden of proof lies on the transmission planner.
NPCC	No	If a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study are we to assume that fulfills the requirements of R2.1 completely, without additional studies of a less-stressed system?
Hydro-Qu?bec Trans?nergie (HQT)	No	If a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study, are we to assume that fulfills the requirements of R2.1 completely, without additional studies of a less-stressed system?
Northeast Utilities	No	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.

Response: R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment".

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

Organization	Question 10:	Question 10 Comments:
TVA System Planning	No	We recommend that sensitivity studies not be required for each of the near term years as required in R2.1.3 and R2.1.1. Sensitivities should only be required for only one year in the near term. These sensitivity study requirements are too prescriptive. Many examples of sensitivities are already inherent in the existing requirements. Sensitivity studies of load variation are inherent in the fact that several different study years and conditions are already being required. Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future with and without the proposed new equipment. The TP and PC can better select the most appropriate sensitivities for their system.
Response: The standard is requiring at a minimum one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Progress Energy Carolinas	No	These requirements are overly prescriptive. Many examples of sensitivities are already inherent in the existing requirements. Some sensitivity studies are in effect adding an additional level of contingency (N-2 or N-3). Sensitivity studies of load variation are already inherent in the fact that several different study years and conditions are already being required. Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future with and without the proposed new equipment. Proper consideration and selection of the most appropriate sensitivities is within the engineering judgment of the Transmission Planner and Planning Coordinator. Singling out and creating sub-requirements for the sensitivities listed in the current TPL draft creates a special focus on these specific sensitivities that may not be warranted for a given system. This could easily lead to an over focus on these particular issues to the detriment of overall system reliability. There should be no enumerated list of required sensitivities. Engineering judgment needs to be permitted.
Response: The SDT believes that sensitivities are necessary and consistent with the requirements of FERC Order 693. The draft standard includes the		

<table>
<tr><th>Organization</th><th>Question 10:</th><th>Question 10 Comments:</th></tr>
<tr><td colspan="3">requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii “Sensitivity studies and critical system conditions”, FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed System conditions. The SDT has included several parameters that can be varied to create the requisite sensitivity case(s).

Requirements R2.1.3 and R2.4.3 have been revised to make it clear that “~~s~~ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment”. The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as “sensitivities”. In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~ensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:</td></tr>
<tr><td>Los Angeles Department of Water and Power</td><td>No</td><td>R2.1.3 and 2.1.4 deal with operating scenarios that need to be studied by operating engineers under TOP but is duplicative and serve no useful purpose when performed by planning engineers for the purpose of future expansions. Transmission planning is to ensure that future system is expanded to handle expected system growth. Mixing operating studies in the planning of future system shows a confused perspective on the different roles between operating studies and planning studies. A responsible utility must perform both types of studies but they should not be mixed together or be required under two different standards, the TOP and TPL. The consideration of load variations, different dispatching scenarios, planned or unplanned transmission outages, system expansion not coming in on schedule, etc., are operating issues that should be and must be addressed in operating studies, and the proper place is in TOP, not TPL.</td></tr>
<tr><td colspan="3">**Response:** The SDT believes that planners must consider these possible variances and reinforce the System so that when it comes to Real-time operation, the TOP will have a System sufficiently robust to operate around any of the conditions. Commenters generally agree that these are the responsibility of planning.</td></tr>
<tr><td>Transmission Agency of Northern</td><td>Yes and No</td><td>We generally agree with the concept of the sensitivity analysis since this is standard practice in understanding system performance risks and the effectiveness of improvements. It is ambiguous from a criteria perspective, however, what role is played by the sensitivities in developing Corrective Action Plans and what risks are created by misapplication of the intent of such sensitivity analyses. Clarification of the following is needed along with examples of applicable sensitivities and how</td></tr>

Organization	Question 10:	Question 10 Comments:
California		these would be factored into Corrective Action Plans. If a Transmission Planner performs studies on the ?base case? of which the loads represented are 1 in 10 year adverse weather condition (10% chance that the actual load may exceed the projected load), does this constitute a sensitivity analysis. If so, will the Transmission Planner have to then perform additional less stringent studies at the load levels representing 1 in 2 year adverse weather conditions (50% chance that the actual load may exceed the projected load) to demonstrate compliance? R2.1.4 requires explanation of performing additional sensitivities that are not listed in the R2.1.3. This would discourage entities from performing additional sensitivities. In addition, in the above example, the Transmission Planners should not have to explain why they feel that this higher level (1 in 10 year adverse weather) of load is the “base case” condition. R2.7 also states that “Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities”. Consider a Transmission Planner that has built transmission based on the 1 in 10 year adverse weather load assumed in the ?base case?, will the judgment of the Transmission Planner be then questioned because the “base case” used is equivalent to a sensitivity case and not a 1 in 2 year adverse weather base case?
Pacific Gas and Electric Co.	Yes and No	We generally agree with the concept of the sensitivity analysis since this is standard practice in understanding system performance risks and the effectiveness of improvements. It is ambiguous from a criteria perspective, however, what role is played by the sensitivities in developing Corrective Action Plans and what risks are created by misapplication of the intent of such sensitivity analyses. Clarification of the following is needed along with examples of applicable sensitivities and how these would be factored into Corrective Action Plans. If a Transmission Planner performs studies on the ?base case? of which the loads represented are 1 in 10 year adverse weather condition (10% chance that the actual load may exceed the projected load), does this constitute a sensitivity analysis. If so, will the Transmission Planner have to then perform additional less stringent studies at the load levels representing 1 in 2 year adverse weather conditions (50% chance that the actual load may exceed the projected load) to demonstrate compliance? R2.1.4 requires explanation of performing additional sensitivities that are not listed in the R2.1.3. This would discourage entities from performing additional sensitivities. In addition, in the above example, the Transmission Planners should not have to explain why they feel that this higher level (1 in 10 year adverse weather) of load is the ?base case? condition. R2.7 also states that ?Corrective Action Plans do not need to be developed solely to meet the performance requirements for

Organization	Question 10:	Question 10 Comments:
		sensitivities?. Consider a Transmission Planner that has built transmission based on the 1 in 10 year adverse weather load assumed in the "base case", will the judgment of the Transmission Planner be then questioned because the "base case" used is equivalent to a sensitivity case and not a 1 in 2 year adverse weather base case?
US Bureau of Reclamation	No	We generally agree with the concept of the sensitivity analysis since this is standard practice in understanding system performance risks and the effectiveness of improvements. It is ambiguous from a criteria perspective, however, what role is played by the sensitivities in developing Corrective Action Plans and what risks are created by misapplication of the intent of such sensitivity analyses. Clarification of the following is needed along with examples of applicable sensitivities and how these would be factored into Corrective Action Plans. If a Transmission Planner performs studies on the ?base case? of which the loads represented are 1 in 10 year adverse weather condition (10% chance that the actual load may exceed the projected load), does this constitute a sensitivity analysis. If so, will the Transmission Planner have to then perform additional less stringent studies at the load levels representing 1 in 2 year adverse weather conditions (50% chance that the actual load may exceed the projected load) to demonstrate compliance? R2.1.4 requires explanation of performing additional sensitivities that are not listed in the R2.1.3. This would discourage entities from performing additional sensitivities. In addition, in the above example, the Transmission Planners should not have to explain Comment Form for 2nd Draft of Standard TPL-001-1Assess Transmission Future Needs (Project 2006-02) Page 9 of 12 why they feel that this higher level (1 in 10 year adverse weather) of load is the ?base case? condition. R2.7 also states that "Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities". Consider a Transmission Planner that has built transmission based on the 1 in 10 year adverse weather load assumed in the ?base case?, will the judgment of the Transmission Planner be then questioned because the ?base case? used is equivalent to a sensitivity case and not a 1 in 2 year adverse weather base case?

Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities".

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

The SDT agrees and has deleted Requirement R2.1.4.

Requirement R2.7 (now R2.6) has been revised for clarity. The entity can use any sensitivities studies it has performed in conjunction with the required current and

Organization	Question 10:	Question 10 Comments:
past studies to develop its Corrective Action Plan. **R2.6** For Planning Events shown in Table 1 ~~– Steady State Performance and Table 2 – Stability Performance~~, when the analysis indicates an inability of the System to meet the performance requirements in the tables, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall:		
National Grid	No	a. With respect to R2.1.3., delete "... that Stress the System with sensitivities ...". b. R2.1.3 should be revised to clarify that if a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study, then additional studies of a less-stressed system are not required. c. The intention of Paragraph R2.1.4 is unclear and appears to be unnecessary; therefore, it should be removed.
Response: a. and b. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: c. Requirement R2.1.4 has been deleted.		
Gainesville Regional Utilities	No	If the RRO or the larger neighboring utilities agree, See Comment 1, it should be unnecessary for the smaller utility to performance any sensitivities except for those agreed to and performed by the RRO level. If the smaller utility has any of their elements that create issues in these regionally conducted sensitivities, then they could be accountable for providing potential remedies (most sensitivities do not necessarily require a remedy or project, per say). The variety of sensitivities suggested to be performed for a smaller utility probably will not add any reliability to the regional BES while the effort will take up a very large amount of the smaller utilities' manpower resources.
Response: All planning entities need to follow the same set of requirements. Smaller entities may not have the resources to perform some studies but can depend on and point to studies run by larger surrounding entities to satisfy their planning requirements.		

<table>
<tr><th>Organization</th><th>Question 10:</th><th>Question 10 Comments:</th></tr>
<tr><td>JEA</td><td>Yes and No</td><td>Will stress JEA resources to provide auditable evidence depending on the final measure applied.</td></tr>
<tr><td colspan="3">Response: The SDT believes that sensitivities are necessary and consistent with the requirements in FERC Order 693. The draft standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii “Sensitivity studies and critical system conditions” FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

The standard is requiring at a minimum one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances.</td></tr>
<tr><td>ITC Holdings: ITC, METC, ITC Midwest</td><td>No</td><td>While we appreciate that the addition of sensitivity studies is commendable and agree with 2.1.3 and 2.1.4 per se, the later clarification in R2.7 that “Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities” negates project justification (to many) based on sensitivity studies. Explaining as per R2.4.3 the reasons why you did or did not run a sensitivity study is less important, in many respects, than why you did or did not provide a Corrective Action Plan for performance failures observed in sensitivity studies. I.e., the study is the “cart” and the CAP is the “horse”. Hence, at a minimum some form of Corrective Action Plan should be required.</td></tr>
<tr><td>PPL EnergyPlus</td><td>Yes and No</td><td>All of the sensitivity requirements should be structured to keep sensitivities from forcing un-needed construction. R2.1.3 & 4 are a good step but the point about planning around the base case might be made even more forcefully.</td></tr>
<tr><td colspan="3">Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that “<s>s</s>ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment”. The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as “sensitivities”. Embedding the sensitivity in the “base case” will result in a CAP that addresses the particular “sensitivities”.

R2.1.3 For each of the studies described in Requirements R2.1.1 and <s>Requirement </s>R2.1.2, sensitivity case(s) that <u>are intended to </u>stress the System with <s>sensitivities </s><u>variations </u><s>that reflect </s><u> in </u>one or more of the following conditions <u>not already included in the studies </u>shall be<s> run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied</s><u> included in the Assessment</u>:

R2.4.3 For each of the studies described in Requirements R2.4.1 and <s>Requirement</s> R2.4.2, <s>s</s>ensitivity case(s) that <u>are intended to </u>stress the System <u>with variations</u> <s>to reflect</s><u> in</u> one or more of the following conditions <u>not already included in the studies </u>shall be<s> run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied</s><u> included in the Assessment</u>:

In addition, Requirement R2.7 (now R2.6) has been revised for clarity. The entity can use any sensitivities studies it has performed in conjunction with the required current and past studies to develop its Corrective Action Plan.

R2.6 For Planning Events shown in Table 1 <s>– Steady State Performance and Table 2 – Stability Performance</s>, when the analysis indicates an inability of the System to meet the performance requirements in the tables, the Planning Assessment shall include Corrective Action Plans addressing how the performance</td></tr>
</table>

Organization	Question 10:	Question 10 Comments:
requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall:		
SMUD	Yes and No	We agree. However, the conditions listed in R3.5.1, R3.5.2 and R3.5.3 are applicable to the overall TPL Standard. Their specific listing in R3.5 gives the impression that these Requirements are only applied to R3.5 and not to the other Requirements in this Standard. In other words, are there any Requirements in this Standard that R3.5.1, R3.5.2 and R3.5.3 do not apply to? Therefore, we suggest TPL-001-1 be silent on this issue and move R3.5.1 through R3.5.3, (and the equivalent in the stability study R5.4.3.1 through R5.4.3.3) to a Requirement applicable to Assessment studies in general, such as the bullet points in the Performance Tables .Added Reference 3.5.1: In cases where an SPS is deployed to reduce thermal overloads such that flows are brought within established facility ratings, but, for a short duration (seconds) until it is fully executed, the facility flows exceed the established rating, is that considered a violation or an acceptable engineering judgment that facilities are judiciously being brought to operate within ratings? Or, should the facility owner ensure establishment of a documented rating even for the short duration of seconds? Q10:TSS response: We generally agree with the concept of the sensitivity analysis since this is standard practice in understanding system performance risks and the effectiveness of improvements. It is ambiguous from a criteria perspective, however, what role is played by the sensitivities in developing Corrective Action Plans and what risks are created by misapplication of the intent of such sensitivity analyses. Clarification of the following is needed along with examples of applicable sensitivities and how these would be factored into Corrective Action Plans. If a Transmission Planner performs studies on the ?base case? of which the loads represented are 1 in 10 year adverse weather condition (10% chance that the actual load may exceed the projected load), does this constitute a sensitivity analysis. If so, will the Transmission Planner have to then perform additional less stringent studies at the load levels representing 1 in 2 year adverse weather conditions (50% chance that the actual load may exceed the projected load) to demonstrate compliance? R2.1.4 requires explanation of performing additional sensitivities that are not listed in the R2.1.3. This would discourage entities from performing additional sensitivities. In addition, in the above example, the Transmission Planners should not have to explain why they feel that this higher level (1 in 10 year adverse weather) of load is the “base case” condition. R2.7 also states that ?Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities?. Consider a Transmission Planner that has built transmission based on the 1 in 10 year adverse weather load assumed in the ?base case?, will the judgment of the Transmission Planner be then questioned because the “base case” used is equivalent to a sensitivity case and not a 1 in 2 year adverse weather base case? Is some Non-Consequential Load Loss for an N-1 contingency on a sensitivity case using an extremely high load forecast acceptable as a Corrective Action Plan in the planning phase?
Response: The SDT agrees with your comment and has deleted Requirements R3.5.1, R3.5.2 and R3.5.3. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that “sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the		

Organization	Question 10:	Question 10 Comments:
studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: The SDT agrees and has deleted Requirement R2.1.4. Requirement R2.7 (now R2.6) has been revised for clarity. The entity can use any sensitivities studies it has performed in conjunction with the required current and past studies to develop its Corrective Action Plan. **R2.6** For Planning Events shown in Table 1 ~~– Steady State Performance and Table 2 – Stability Performance~~, when the analysis indicates an inability of the System to meet the performance requirements in the tables, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall:		
Progress Energy Florida, Inc.	No	PEF has significant concerns with each of the sub-Requirements listed in R2.1.3. Each is ambiguous, vague and open to variations in interpretation. It therefore makes no sense that "documentation of the technical rationale for why each of the conditions was or was not selected" is a requirement. Indeed, given that all of the sub-Requirements of R2.1.3 are vague, unspecific, unwieldy concepts, PEF is not sure how said documentation could be accomplished. Concerning R2.1.4, PEF has the same concerns that were expressed regarding the modified requirements mentioned in Question 2, and similarly here would suggest a substitute to the language in R2.1.4. Significant concerns with the previous sub-Requirements notwithstanding, PEF suggests either returning to the language in each existing Standard's R1.3.2, or adding an R2.1.3.8 that states "Other known critical system conditions specific to the system studied by the Transmission Planner or Planning Coordinator."
Response: The SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies. In addition, Requirements R2.1.3 and R2.4.3 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. Since these are sensitivities, any and all variances provide some level of information as to how the System responds to such variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical~~		

Organization	Question 10:	Question 10 Comments:

Lafayette Utilities System	No	As to the performance of sensitivity analyses under R2.1.3, Lafayette believes that insufficient detail is provided to define with clarity cases that involve ?modification of expected transfers? (per R2.1.3.2). For example, it is unclear whether the phrase ?modification of expected transfers? is intended to refer to a change in directional bias in the model, a reduction in flows due to variation between reservations and schedules, or something else. Additional definition should be provided to ensure that sensitivity cases performed pursuant to R2.1.3.2 are meaningful and useful.
Response: The SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies		
Ameren	No	Similar to our comment above for R2.4.3, there should not be a requirement to explain why sensitivities were not selected. Also, it is not clear if R2.1.4 is a requirement or an option. While we agree that the system cannot be adequately planned based on a single snapshot of expected system conditions, these items in R2.1.3.1-7 are too prescriptive and are inappropriate for inclusion here. The sensitivities listed appear to be options and not sub-requirements, and may result in over-focusing on the particular issues listed to the detriment of overall system reliability. Some sensitivity studies are in effect adding an additional level of contingency to the analysis work (n-2 or n-3). Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future system with and without the proposed new equipment. Engineering judgment should be used to develop the sensitivity scenarios, and it should be encouraged that the same scenarios should not be performed every year so that a portfolio of sensitivity scenarios would be developed over time. The standard should not include an enumerated list of required sensitivities. If two sensitivities are required to be performed each year, then the standard should state so, but we believe that more than one sensitivity scenario for each peak and off-peak case per year for assessment is too burdensome to run complete contingency analyses. Proposed alternative wording for R2.1.3 which addresses above concerns is as follows:R2.1.3. "For each of the studies described in Requirement R2.1.1 and Requirement R2.1.2, sensitivity case(s) that stress the System to reflect one or more conditions such as variation in load assumptions, modification of expected transfers, variability and outages of reactive resources, generation additions, retirements, or other dispatch scenarios are integral to a thorough assessment of reliability. Document how and why appropriate sensitivities were selected."
Response: Requirements R2.1.3 and R2.4.4 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run.		

Organization	Question 10:	Question 10 Comments:
Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Florida Power and Light	No	The words ?documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied? should be removed from R2.4.3. The sensitivity selection is necessarily subjective and judgmental. It is not clear what constitutes a valid rationale document. Compliance assessment of such a document would be subjective and is not needed.
Response: Requirements R2.1.3 and R2.4.3 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. The SDT believes that documentation of why a sensitivity was selected for study should be provided. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Exelon Transmission Planning	No	We support efforts to improve load and dynamic load modeling, however we have concerns in being able to do so in an accurate manner - See comments to question #2. The state of industry development is such that this is not ready for inclusion in a standard such as R2.4.1 and R2.4.3.1.
Response: As with all planning models, assumptions must be made that the entity feels are representative of how the system will respond and perform. Models can only attempt to simulate the System based on expected conditions. The standard has been modified to explain that "an aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable".		

Organization	Question 10:	Question 10 Comments:
R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable		
CenterPoint Energy and CPS Energy	No	We believe R2.1.3 and R2.1.4 are overly prescriptive and should be deleted. It requires engineering judgment and experience to know whether a planning analysis is materially impacted by certain assumptions and, if so, which sensitivity analyses should be performed. Literally interpreted by an auditor, R2.1.3 would require at least one sensitivity analysis for each one of the contingencies shown in Tables 1 and 2 for each study specified in R2.1.1 and R2.1.2 and documentation for each contingency of each study why each sensitivity specified in R2.1.3 was or was not selected. The likely result is not value-added engineering analysis of actual reliability concerns. Instead, the likely outcome is unnecessary and burdensome additional analysis and documentation that is impractical, creating confusion and uncertainty as to what the practical interpretation of impractical requirements might ultimately be.
SERC Dynamics Review Subcommittee	No	These requirements are very prescriptive. Many examples of sensitivities are already inherent in the existing requirements. Some sensitivity studies are in effect adding an additional level of contingency (N-2 or N-3). Sensitivity studies of load variation are already inherent in the fact that several different study years and conditions are already being required. Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future with and without the proposed new equipment. The TP and PC can better select the most appropriate sensitivities for their system. In general we believe that breaking these requirements into specific sub requirements, focusing on specific sensitivities, is too prescriptive and inappropriate. It will lead to over focus on these particular issues to the detriment of system reliability. There should be no enumerated list of required sensitivities. Engineering judgment needs to be permitted.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written the standard is requiring at a minimum one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances. In addition, Requirements R2.1.4 and R2.4.4 have been deleted. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the~~		

Organization	Question 10:	Question 10 Comments:
~~conditions was or was not selected shall be supplied~~ included in the Assessment:		
MidAmerican Energy Company	No	a. MEC is not sure why R2.4.3.1 for sensitivities for Stability studies is a less definitive definition for load model variations then the steady state studies in R2.1.3.1. MEC recommends that R2.1.3.1 be changed to "Variations in Load model assumptions." b. MEC believes R2.1.4 and R2.4.4 should be deleted because its unnecessary to make a requirement of sensitivities that an entity chooses to do above and beyond the requirements in R2.1.3 and R2.4.3. If the SDT chooses not to delete these requirements, then MEC believes that R2.1.4 should be a subrequirement of R2.1.3 and R2.4.4 should be made a subrequirement of R2.4.3. The responsible entity should be allowed to select the appropriate sensitivity that should be performed. This is especially necessary given the need to perform each of these sensitivity analyses for six situations each year: peak and off-peak for two short-term years and one long-term year. Even with the requirement for one sensitivity for each case that amounts to six additional sets of analysis for steady-state and six for stability.
Response: a. As with all planning models, assumptions must be made that the entity feels are representative of how the System will respond and perform. Models can only attempt to simulate the System based on expected conditions. The standard has been modified to explain that "an aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable". **R2.4.1** System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable b. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances. In addition, Requirements R2.1.4 and R2.4.4 have been deleted. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
MRO NERC	No	a. The MRO is not sure why R2.4.3.1 for sensitivities for Stability studies is a less definitive definition for load model

Organization	Question 10:	Question 10 Comments:
Standards Review Subcommittee		variations then the steady state studies in R2.1.3.1. The MRO recommends that R2.1.3.1 be changed to "Variations in Load model assumptions." b. The MRO believes R2.1.4 and R2.4.4 should be deleted because its unnecessary to make a requirement of sensitivities that an entity chooses to do above and beyond the requirements in R2.1.3 and R2.4.3. If the SDT chooses not to delete these requirements, then MRO believes that R2.1.4 should be a subrequirement of R2.1.3 and R2.4.4 should be made a subrequirement of R2.4.3. The responsible entity should be allowed to select the appropriate sensitivity that should be performed. This is especially necessary given the need to perform each of these sensitivity analyses for six situations each year: peak and off-peak for two short-term years and one long-term year. Even with the requirement for one sensitivity for each case that amounts to six additional sets of analysis for steady-state and six for stability. c. For R2.1.4, we suspect that these analysis are similar to extreme event contingencies and do not have specific performance requirements. We would also like some explanation of what and how to provide the technical rationale for why each condition was or was not used.

Response: As with all planning models, assumptions must be made that the entity feels are representative of how the System will respond and perform. Models can only attempt to simulate the System based on expected conditions. The standard has been modified to explain that "an aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable".

R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable.

b. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances. In addition, Requirements R2.1.4 and R2.4.4 have been deleted.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

c. Requirement R2.1.4 has been deleted.

Organization	Question 10:	Question 10 Comments:
Austin Energy	No	Appropriate sensitivity analysis should be determined by the Transmission Planner and/or the Planning Coordinator (ISO or RTO) and not made a routine requirement. Therefore, R2.1.3 should be deleted.
SERC Reliability Review Subcommittee and Planning Standards Subcommittee	No	These requirements are very prescriptive. Many examples of sensitivities are already inherent in the existing requirements. Some sensitivity studies are in effect adding an additional level of contingency (N-2 or N-3). Sensitivity studies of load variation are already inherent in the fact that several different study years and conditions are already being required. Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future with and without the proposed new equipment. The TP and PC can better select the most appropriate sensitivities for their system. In general we believe that breaking these requirements into specific sub requirements, focusing on specific sensitivities, is too prescriptive and inappropriate. It will lead to over focus on these particular issues to the detriment of system reliability. The standard should not include an enumerated list of required sensitivities Engineering judgment needs to be permitted.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that “sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment”. The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as “sensitivities”. In addition, as written the standard is requiring at a minimum one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Midwest ISO	No	This reminds us of Category D from original table--requiring us to study something but take no action. Sensitivities are not appropriate nor effective in a planning world in which you require an array of sensitivity studies but require no action will be taken. While running sensitivities enables us to better understand system limits, why have it as a requirement if there is no action plan obligation.
Response: The requirement was added to ensure that the entities do run certain variances that would stress the System. Requirement R2 requires that such studies are documented as part of the Planning Assessment. The entity is to determine the risk associated with not modifying the Corrective Action Plan to consider these studies. The documentation puts the entity on record as stating that the variance was considered but may or may not have been incorporated in the Plan makes the entity liable for its decision.		

Organization	Question 10:	Question 10 Comments:
Tri-State Generation and Transmission Association, Inc.	No	We appreciate the extra detail describing sensitivity cases, but do not think it is reasonable to require explanations of why each condition suggested in R2.1.3.1-R2.1.3.7 was or was not studied. It should be sufficient that sensitivity studies are considered appropriate by the individual utility. R2.1.4 should be demoted to R2.1.3.8 (and the "shall include rationale" clause removed).
Response: Requirements R2.1.3 and R2.4.3 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. The SDT believes that documentation of why a sensitivity was selected for study should be provided. Requirements R2.1.4 and R2.4.4 have been deleted. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~ensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Lakeland Electric	No	R2.1.3.1 requires other than peak sensitivity studies while R2.1.2 requires Off peak studies. Recommend further defining of R2.1.2 to specific load level or points on forecast demand curves to eliminate any overlap between two requirements.
Response: The SDT has used the defined term "Off-Peak" and believes that this is sufficient.		
Southern Company Transmission	No	R 2.1.3 One should only have to explain why sensitivity was performed, not why it was not performed. In general we believe that breaking these requirements into specific sub requirements focusing on specific sensitivities is too prescriptive and inappropriate. It will lead to over focus on these particular issues to the detriment of system reliability. There should be no list of sensitivities enumerated as subrequirements. Engineering judgment needs to be permitted. A specific proposal for R2.1.3 which addresses the above concerns is provided as follows:R2.1.3. For each of the studies described in Requirement R2.1.1 and Requirement R2.1.2, sensitivity case(s) shall be run and documented that stress the System to reflect one or more conditions such as higher or lower Load than forecasted with variability of Load/demand and Load power factors due to season, weather, or time of day; modification of expected transfers; unavailability of long lead time Facilities; variability and outages of reactive resources; generation additions, retirements, or other dispatch scenarios; decreased effectiveness of controllable Loads and Demand Side Management; modification of planned Transmission outages. Document why each sensitivity was selected.
Response: Requirements R2.1.3 and R2.4.4 have been revised to remove the requirement you reference. In addition, Requirements R2.1.3 and R2.4.3 have been		

Organization	Question 10:	Question 10 Comments:
revised to make it clear that “~~s~~ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment”. The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as “sensitivities”. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Brazos Electric Power Cooperative, Inc.	No	2.1.3 should have been left alone. We have a real problem with the addition of 'technical' and documenting why things were NOT selected. We would also like to see more leeway provided to the TP and PC by adding language similar to that mentioned above such as "as deemed necessary by the TP or PC".2.1.4 should be incorporated into 2.1.3 in a similar fashion as our suggested changes for 2.4.3.
Response: Requirements R2.1.3 and R2.4.4 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. In addition, Requirements R2.1.3 and R2.4.3 have been revised to make it clear that “~~s~~ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment”. The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as “sensitivities”. In addition, Requirements R2.1.4 and R2.4.4 have been deleted. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~ensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
NERC and Regional Coordination	No	The standard as worded:? Implies all tests are run for a given sensitivity the standard should be revised to read applicable testing for the applicable sensitivity.? Requires proof of negative o Why a sensitivity was not selected? Requires that expansion plans identify the impact of sensitivity o Many sensitivities may have varying impacts on an expansion plan. Suggested changes:R2.1.3 - For each of the studies described in Requirement R2.1.1 and Requirement R2.1.2, sensitivity case(s) that reflect one or more of the following conditions shall be incorporated into the assessment. Documentation of the

Organization	Question 10:	Question 10 Comments:
		technical rationale for why each of the conditions was selected and the portion of the assessment that included each selected sensitivity shall be supplied. R2.1.4, R2.4.3, and R2.4.4 - need to be modified accordingly. Delete R2.1.4 as it is superfluous. If a PC runs a sensitivity study and includes that analysis in its Plan, then why would NERC mandate that the PC explain why the non-mandated sensitivity study was run. If a study is required then it should be mandated. If a study is not mandated then he PC should not be held accountable for explaining the un-mandated study.R2.4.3.1 ? Variation in load model. Specific numbers should be included. R2.4.3.2 - Modification of expected transfers ? Be more specific. Firm or non-firm transfer and amount of MWR2.4.3.3 - Unavailability of long lead time Facilities. How many years out we are looking at and for how long it must be out of service.R2.4.3.4 - Variability of Reactive Source ? need to be more specific (give me MVARS). We already test this under FAC 010 for lost of shunt capacitor.R2.4.3.5 - This should already been taken into account when we do studies. So be more specific.R2.7.2 - Include a description of how results of the sensitivities selected in accordance with Requirements R2.1.3, R2.1.4, R2.4.3, and R2.4.4 impacted the list of actions developed in accordance with R2.7.1.R2.1 - Revise wording - The annual assessment of the of the NT Planning Horizon shall include: then go into the sub-bullets. The SDT must clarify exactly explicitly how many studies (in terms of numbers) must be done each planning horizon for short term and long term and how much sensitivity study for term.

Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities".

Also, Requirements R2.1.3 and R2.4.3 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

The SDT agrees with the commenter and has deleted Requirements R2.1.4 and R2.4.4.

The SDT did not want to be more prescriptive and provide specific details and number for variances that the entity may select because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies.

Requirement R2, along with its sub-requirements, requires the sensitivities run are to be documented. Requirement R2.6 requires that the Corrective Actions be listed. The entity can add the details and further explanation of how the sensitivities were incorporated into the Plans.

Organization	Question 10:	Question 10 Comments:
Since the basis of the standard is to allow the entity to support the Planning Assessment using current and past studies, the standard cannot dictate the specific number of studies to be made. The standard does specify the current cases that must be run in Requirements R2.1.1, R2.1.2, R2.2, R2.4.1 and R2.4.2.		
IESO	No	As we commented on R2.4.3, we continue to express our disagreement to include sensitivity testing in R2.1.3 and R2.1.4. We are disappointed that despite disagreements by the majority of the commenters and their suggestions to leave sensitivity testing to the TP's and PC's discretion, the SDT continues to stipulate detailed requirements for sensitivity testing. The SDT in its summary response to comments indicates that these testing are intended as "?providing some guidance on what could be included in the sensitivity studies without being too prescriptive." If these are indeed intended as guidance rather than enforceable requirements, then they should be provided in a technical document or a reference document that supports the standard, not in the standard itself.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances.		
North Carolina Electric Membership Corp	Yes and No	Sensitivities to base assumptions for studies are always good utility practice. But we agree with others that these may be overly prescriptive in requiring each and every one. Allow the TP and PC to select the appropriate sensitivities for the annual assessments with input from customers and affected stakeholders. We are concerned that the requirement for every sensitivity each and every year would result in excessive burden to existing PCs and TPs doing this analysis with no resulting improvement to reliability.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written the standard is requiring at a minimum one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances.		
E.ON U.S. Transmission Planning	Yes and No	2. R2.1.3.2 refers to modification of expected transfers as a sensitivity test. Does this include transfers across the system, such as a transfer from Cinergy to TVA?
Response: The SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies		

Organization	Question 10:	Question 10 Comments:
ERCOT System Planning		The sensitivity cases suggested are unnecessary and unfeasible. For example, generation additions to cases that can already meet the load under contingency conditions do not create a reliability problem as the new generator can always be turned off. On the other extreme, sensitivity analysis of possible, unknown and uncontrollable generation retirements along with the Table 1 requirements of P3 (Generator + 1) contingency analysis presents an overwhelming study and documentation burden that will not add a corresponding benefit to the study and the results would be meaningless.
Response: The SDT believes that planners must consider these possible variances and reinforce the System so that when it comes to Real-time operation, the TOP will have a system sufficiently robust to operate around any of the conditions. Commenters generally agree that these are the responsibility of planning. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
American Transmission Company	No	For R2.1.3, we would like further explanation of what technical rationale is expected and how it should be provided as to why each condition sensitivity was or was not used. In the subrequirements, we are unsure of what is exactly meant by "variability of load demand and load power factors", "modification of expected transfers", "long lead time Facilities", and "modification of planned outages". For R2.1.4, it is unclear what specific performance requirements must be met for these other sensitivities. We would also like some explanation of what technical rationale is expected and how it should be provided as to why each condition sensitivity was or was not used.
Response: Requirements R2.1.3 and R2.4.4 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. Since these are sensitivities, any and all variances provide some level of information as to how the system responds to such variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the~~		

Organization	Question 10:	Question 10 Comments:
~~conditions was or was not selected shall be supplied~~ included in the Assessment: The SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies. Also, Requirements R2.1.4 and R2.4.4 have been deleted.		
Duke Energy	No	Although we agree with the perceived intent of R2.1.3, we believe the wording should be revised to make it very clear that it is not necessary to perform studies to substantiate your technical rationale for choosing not to perform any particular sensitivity study. Documented engineering judgment to support the decision not to perform the particular sensitivity studies should be sufficient. Recommend renumbering R2.1.4 to R2.1.3.8 and reword as follows: Any other sensitivity, as deemed appropriate by the Transmission Planner or Planning Coordinator for their individual systems.
Florida Reliability Coordinating Council, inc	No	R2.1.3 and R2.1.4 as written can create issues during the compliance assessment. These requirements place the burden of justifying the inclusion / exclusion of the sensitivities on the TP or PC. Thus, only a sensitivity deem appropriate by the TP or PC and not performed can be found non-compliant. R2.1.4 can be eliminated by modifying the wording in R2.1.3 as follows:? For each of the studies described in Requirement R2.1.1 and Requirement R2.1.2, at least one sensitivity shall be performed that stress the system based on one or more of the following conditions, plus any additional conditions determined by the Transmission Planer and Planning Coordinator. The Planning Assessment will also include the technical rationale for why each of the conditions was or was not selected for study that year.?
Response: Requirements R2.1.3 and R2.4.4 have been revised to remove the requirement to explain why sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. Since these are sensitivities, any and all variances provide some level of information as to how the system responds to such variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
Central Maine Power Company	No	a. With respect to R2.1.3 delete "that Stress the System with sensitivities". b. R2.1.3 should be revised to clarify that if a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study, then additional studies of a less-stressed system are not required.

Organization	Question 10:	Question 10 Comments:
		c. The intention of Paragraph R2.1.4 is unclear and appears to be unnecessary; therefore, it should be removed.
ISO New England Inc.	No	a. With respect to R2.1.3 delete " that Stress the System with sensitivities". b. R2.1.3 should be revised to clarify that if a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study, then additional studies of a less-stressed system are not required. c. The intention of Paragraph R2.1.4 is unclear and appears to be unnecessary; therefore, it should be removed.
ColumbiaGrid	Yes	We generally agree with the concept of the sensitivity analysis since this is standard practice in understanding system performance risks and the effectiveness of improvements. R2.1.4 requires explanation of performing additional sensitivities that are not listed in the R2.1.3. This would discourage entities from performing additional sensitivities. In addition, in the above example, the Transmission Planners should not have to explain why they feel that this higher level (1 in 10 year adverse weather) of load is the ?base case? condition.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: The SDT agrees and has deleted R2.1.4.		
NSTAR Electric	No	1. With respect to R2.1.3 delete "that Stress the System with sensitivities".2. R2.1.3 should be revised to clarify that if a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study, then additional studies of a less-stressed system are not required.3. The intention of Paragraph R2.1.4 is unclear and appears to be unnecessary; therefore, it should be removed.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with		

Organization	Question 10:	Question 10 Comments:
~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: Requirements R2.1.4 and R2.4.4 have been deleted.		
New York Independent System Operator	No	If a TP/PC conducts the studies specified in R2.1.1 and R2.1.2 with one or more of the sensitivities which stress the system in the normal course of study, we assume that fulfills the requirements of R2.1 completely, without additional studies of a less-stressed system. Is that correct?
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: The standard expects that at least one more of those variances listed in Requirement R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written the standard is requiring at a minimum one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the System responds to the variances.		
Oncor Electric Delivery	Yes	Generally agree with modifications although would again stress that detailed load modeling for stability analysis may be as revealing as some of the sensitivity studies recommended in R2.1.3 if they were only run with steady state analysis.
Response: As with all planning models, assumptions must be made that the entity feels are representative of how the System will respond and perform. Models can only attempt to simulate the System based on expected conditions. The standard has been modified to explain that "an aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable". **R2.4.1** System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic		

Organization	Question 10:	Question 10 Comments:
behavior of the Load is acceptable.		
FirstEnergy Corp.	No	The requirements related to sensitivity cases as written in draft 2 are an improvement over draft 1 as they now allow flexibility in choosing sensitivities, compared to what use to be a fixed list of options. However, we do not agree with the need to document the technical rationale for why each listed condition was or was not selected. This seems to create a needless paper trail from an auditing viewpoint. If any documentation is needed, it should be limited to why the sensitivity was selected and it should not be required to indicate why others were not selected. Therefore, we suggest rewording 2.3.1 as follows: "For each of the studies described in Requirement R2.1.1 and Requirement R2.1.2, sensitivity case(s) that stress the System with sensitivities that reflect one or more of the following conditions shall be run and documentation of the technical rationale for why each of the conditions was selected shall be supplied:"R2.1.4 - This is an optional requirement and should be worked into the list of options within 2.1.3. As a stand alone requirement, what type of measure or VSL would be applicable for this requirement? We suggest re-numbering this requirement as a new 2.1.3.8 and reword it as follows: "Any other sensitivities, as deemed appropriate by the Transmission Planner or Planning Coordinator for their individual systems".R2.1.3.3 ? This requirement indicates sensitivity is needed for "Unavailability of long lead time facilities." Why is this required in a near-term planning horizon? How long is long? Doesn't the N-1-1 (Planning Event P6) test already account for this related to the outage of existing equipment which may present long lead times? Same comments apply for R2.4.3 and R2.4.4 in the stability study section.
Response: Requirements R2.1.3 and R2.4.3 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: The STD agrees. Requirements R2.1.4 and R2.4.4 have been deleted. The near-term horizon extends from one to five years. Equipment scheduled for installation in five years requires ordering today. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "~~s~~sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities".		
Orlando Utilities	Yes and No	I generally agree with the intent of requiring studies beyond just one load level and system condition; however I have some

Organization	Question 10:	Question 10 Comments:
Commission		specific suggestions, questions and comments. R2.1.3: As worded I have several concerns: 1. This would make any study performed that did not include sensitivities useless for performing the assessment. I recommend identify sensitivities and studies separately, with sensitivities just being smaller versions of studies. (Our usual definition is that a study demonstrates specific solutions to problems identified, whereas a sensitivity merely comments on the presence or lack of problems and how they relate to what is seen in the more formal studies. Obviously a problem found in a sensitivity not seen in a regular study receives additional focus.) 2. This would force the study to look only at the sensitivities listed rather then allow one or more of the conditions, plus additional conditions all in one run. This would force an entity to run additional studies if they wished to exceed the requirements rather then a single study that meets and exceeds the requirements. I suggest the following wording instead to still require the sensitivities, but allow flexibility in how they are performed. "R 2.1.3: At least one sensitivity shall be performed that stress the system based on one or more of the following conditions, plus any additional conditions determined by the transmission planner and planning coordinator. The Planning Assessment will also include the technical rationale for why each of the conditions was or was not selected for study that year. R.2.1.3.1- Suggest adding system growth, for example "season, weather, unpredicted system growth, or time of day". As written it does not seem to allow a study based on the long range load growth prediction being off, but instead only on a change in season, weather or time of day. R2.1.4: What was intended by using the phrase "Documentation of the technical rationale" instead of simply saying "shall include technical rationale"? I suggest dropping the "documentation of the" as this could cause confusion on an audit as to what is the difference between the "technical rationale" and "documentation of the technical rationale" unless the drafting team plans to define what "documentation of technical rationale is" other then the rationale itself.

Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that “~~s~~ensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment”. The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as “sensitivities”. In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~ensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

The SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which

Organization	Question 10:	Question 10 Comments:
and how much of a variance is appropriate for its studies. Requirements R2.1.3 and R2.4.4 have been revised to remove the requirement to explain why a sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. Since these are sensitivities, any and all variances provide some level of information as to how the system responds to such variances. Requirements R2.1.4 and R2.4.4 have been deleted		
Entergy Services, Inc.	No	R2.1.3.2 - Modification of expected transfers: Modification of expected transfers infers that non-firm transmission use would be estimated based on historical data or perhaps an economic outlook. To plan the system for such non-firm use is an imprudent burden on rate payers. Economic tools are available to ascertain the benefits of system upgrades and prudently allocate the costs of such upgrades. Generation assets and the future plans of those assets is market sensitive information that could easily be extracted from such sensitivity analyses. Results of these sensitivity studies should be used to aid in reliably operating the system. They should not be a basis for constructing transmission facilities for reliability. These types of studies are aligned with the operating horizon. See also comments made above regarding 2.1.3.4 and 2.1.3.7.In general, we believe that breaking these requirements into specific sub requirements, focusing on specific sensitivities, is too prescriptive and inappropriate. It will lead to over focus on these particular issues to the detriment of system reliability. There should be no enumerated list of required sensitivities. Engineering judgment needs to be permitted. Many examples of sensitivities are already inherent in the existing requirements. Some sensitivity studies are in effect adding an additional level of contingency (N-2 or N-3). Sensitivity studies of load variation are already inherent in the fact that several different study years and conditions are already being required. Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future with and without the proposed new equipment. The TP and PC can better select the most appropriate sensitivities for their system. We recommend that engineering judgment continue to be recognized as a vital component of planning.
Response: Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities". In addition, as written, the standard is requiring at a minimum, one case run for each required current year for steady state and Stability. This translates into three cases for steady state. The entity may run as many additional cases as it deems appropriate to understand how the system responds to the variances. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		

Organization	Question 10:	Question 10 Comments:
The SDT believes that planners must consider these possible variances and reinforce the System so that when it comes to Real-time operation, the TOP will have a System sufficiently robust to operate around any of the conditions. Commenters generally agree that these are the responsibility of planning. The SDT did not want to be more prescriptive because of the huge number of possible variances that can occur. It is up to the planning entity to determine which and how much of a variance is appropriate for its studies.		
BPA Transmission Reliability Program	No	For those conditions that are "not" studied, it makes sense to explain why that particular condition was not selected. However, we do not agree with R2.1.3 that a rationale needs to be provided for why a particular sensitivity "is" selected for study. Running additional sensitivities provides a better understanding of system performance and doesn't need further justification. Requirement R2.1.4 is not needed and should be removed. It should be up to the Transmission Provider's discretion whether they run additional sensitivity studies beyond what the standard requires in R2.1.3, and it should not be necessary to justify why they chose to run them. What a sensitivity study consists of, needs further clarification. For example, if a system assessment is performed using a case with transmission paths stressed near their limits, is this considered the baseline or a sensitivity? If it is considered the baseline, would a sensitivity be required at reduced stress levels and what purpose would this serve when the original case produced the more severe system impacts? This needs further clarification.
Response: Requirements R2.1.3 and R2.4.3 have been revised to remove the requirement to explain why sensitivity was not run since it would be necessary to run the study regardless to provide proof why it was not run. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: Requirements R2.1.4 and R2.4.4 have been deleted. Requirements R2.1.3 and R2.4.3 have been revised to make it clear that "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment". The standard expects that at least one more of those variances listed in Requirements R2.1.3 and R2.4.3 that have not been integrated into the required studies are at least considered as "sensitivities".

11. **In response to industry comments, the SDT modified Table 1 requirements for Planning Event P6. Planning Event P6 involves independent overlapping single contingencies (n-1-1) involving two Transmission Facilities excluding generators. This Planning Event generally correlates to P5 of the first draft and now includes shunt devices. The P6 event was also revised to permit loss of Non-Consequential Load to meet performance requirements for Systems above 300 kV.**

    Do you concur with the modifications? If not, please state why and/or suggest specific changes.

Summary Consideration:

A substantial majority of the industry respondents agree with the revision to permit loss of Non-Consequential Load to meet performance requirements for P6 Events involving systems above as well as below 300 kV, considering the low probability of such Events.

There are concerns that this change would make it difficult for scheduling maintenance outages because the existing TPL-003-0 allows shedding of Non-Consequential Load after the next outage . However, in the proposed standard, If a facility is scheduled out of service for maintenance, the next outage would be considered a single Contingency Event, and loss of Non-Consequential Load is not permitted.

There are concerns expressed by numerous respondents that after the first single Contingency and System adjustment, curtailment of Firm Transmission Services (or firm transfers) and shedding of firm Load would not be allowed in preparation for the second Contingency. The SDT added Footnote # 10 to the end of Table 1 to reflect that Curtailment or Interruption of Firm Transmission Service in preparation for the next Contingency will be allowed. However, until the next Contingency occurs, System performance will need to meet the requirements for a single Contingency Event. As such, the proposed standard will not allow loss of any firm Non-Consequential Load, except for contracted Interruptible Loads, in preparation for the next Contingency. Nonetheless, the SDT has provided an exception (Requirement R2.6.4) to address those situations, which may arise that are beyond the control of the Transmission Planner or Planning Coordinator, and, which can prevent the implementation of the relevant Corrective Action Plan in the required timeframe.

Some respondents requested that System adjustment be defined. The SDT believes that Header note ‘e’ and the new Footnote # 10 provides the description of the System adjustments allowed after a first Contingency Event.

There were also requests for clarification between a P1 Event, which occurred after another Facility has been out of service, for example, for scheduled maintenance, and a P6 Event, since the former will not allow loss of Non-Consequential Load, while the latter would allow it. The SDT believes that the difference between these two Events is whether the prior outage was planned (such as maintenance) or anticipated (such as extended outage). Therefore, if the Prior outage is planned or anticipated, then the next N-1 is a single Contingency Event, otherwise, it would be a P6 Event.

Concerns were also expressed that the TP and PC should have discretion on the Contingencies (for example, shunt devices) to study and analyze. One response suggests that the P6 Event to be studied should have a common reason to occur. The SDT modified Requirement R3.3 (now R3.4) to allow the PC and TP to determine the single and multiple Contingencies to be included in the planning analyses. This would give the TP and the PC the discretion to study the Contingency most suited to the area of study, and they can choose not to study loss of shunt devices, or those P6 Events that do not have a common reason to occur, if these are less severe than the Events studied.

Some responses suggest that there should be a specific limit to the amount of Load loss allowed. While the SDT does not disagree with having some specific limits below which Load loss would be allowed, arriving at such an amount may be too case-specific and too prescriptive for a Continent-wide Standard.

One response disagrees that the requirement should be so much more severe for an internal breaker fault as opposed to two single line outages for elements over 300 kV. The SDT believes that an internal breaker fault would remove from service all Facilities connecting to the faulted breaker simultaneously, which would likely be more severe than outage of two single lines.

As a result of industry comments, the following requirements were changed:

R3.3.3 (now R3.4) Those Planning Event Contingencies in Table 1 ~~– Steady State Performance not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.

Header note 'e' - For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

Organization	Question 11:	Question 11 Comments:
Dominion - Electric Transmission Planning	No	For Bulk Electric System (BES) Elements out of Service above 300 kV, interruption of Firm Transmission Service and Non-Consequential Load Loss should not be allowed. We favor the language proposed in the previous draft.
ITC Holdings: ITC, METC, ITC Midwest	No	Allowing load loss for shutdown plus contingency might seriously jeopardize maintenance outages when you actually encounter this situation in real-time. It's easy to say these things in the ?planning horizon? but it might be politically unacceptable for "real-time". This is particularly true for higher voltage systems above 300kV. We understand that there could be "load-pocket" situations at lower voltages where this might be allowed but EHV systems are back-bone systems. This would set a bad precedent if allowed.
Lafayette Utilities	No	Lafayette does not agree that the loss of Non-Consequential Load should be permitted as a corrective action. See also

Organization	Question 11:	Question 11 Comments:
System		paragraph (b) in response to Question 15.
Arkansas Electric Coop. Corp.	No	Non-Consequential Load Loss should not be allowed. See comments to question 7.
Response: Thank you for your comments but the majority of the industry respondents agree with the revision to permit loss of Non-Consequential Load to meet performance requirements for P6 Events involving Systems above as well as below 300 kV considering the low probability of such Events.		
City Water, Light & Power - Springfield, Illinois	Yes and No	Shunt devices should only need to be included in contingency analysis at the discretion of the TP or PC.
CenterPoint Energy and CPS Energy	No	We believe P6 should be deleted. As noted earlier, we believe credible multiple contingencies should be studied as planning events, with incredible multiple contingencies possibly considered as extreme events. If P6 is retained, we believe loss of shunt devices should not be studied and believes the ability to systematically study the contingency loss of every individual switched shunt device is not supported by commercially available PTI software because up to this point it has not generally been recognized as a necessary or desirable analysis to perform. Also, if P6 is retained, we believe loss of Non-Consequential Load should be permitted at any voltage level for this type of extreme event.
Response: Requirement R3.3.3 (now Requirement R3.4) was modified to allow the PC and TP to determine the single and multiple Contingencies to be included in the planning analyses. This would give the TP and the PC the discretion to study the Contingencies most suited to the study area, including whether to include shunt devices in the analyses. **R3.4** Those Planning Event Contingencies in Table 1 ~~– Steady State Performance~~ ~~not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.		
Progress Energy Carolinas	No	While we agree interruption of firm transmission service and non-consequential load loss should not be allowed to meet the planning requirements for the first system contingency (defined as initial system condition in the table), these system adjustments should be allowed to prepare for the second event so that the system will meet the requirements following the second event. We recommend that clarifying changes be made to ensure that this is clearly understood. One suggestion would be to include the following footnote to P6 in both the Steady State and Stability Tables.? Foot note: Interruption of firm transmission service and/or non-consequential load loss is allowed after the first event as a System adjustment to prepare

Organization	Question 11:	Question 11 Comments:
		for and meet the requirements of the second event. See also our related response to question 15.
Gainesville Regional Utilities	Yes and No	I believe some clarification is needed to specify that you can or can not curtail firm transmission service prior to the next event, because as written it could lead to compliance audit issues. I don't believe the intend of order 693 was to cause a need for utilities to be exposed to large cost increases for their customers while very little to no improvement in reliability is provided as it deals with very low probability conditions which would yield no increase in transfer capability.
JEA	Yes and No	JEA agrees with the changes on the surface, but still does not agree with the concept that it can not curtail Firm Transmission Service after the first N-1 event in preparation for the second N-1 event. JEA's existing Firm Transmission Service customers understand the need to maintain these existing transmission loading relief procedures in order to maintain security of the BES. The only JEA system element that causes this concern has a very high availability and would have a very costly infrastructure improvement to meet this requirement resulting in all of JEA's Firm Transmission Service Customers experiencing increased service cost or in the worst case having their service opportunities permanently curtailed.
Florida Power and Light	No	The P6 Planning Event is not clearly defined. It appears that the Initial System Condition is the Planning Event of P1, with the ?System Adjustments? allowed under P1 to keep facilities within the applicable ratings. R3.5.3. requires that a sustainable, stable, operating condition is maintained. This does not state prepared for the next contingency?. Given FERC's interpretation of TPL-002-0 Category B (see paragraphs below for excerpts from Order 693) that the system is not required to be able to withstand another N-1 contingency, the proposed new standard appears to require that this state be "sustained" indefinitely after a P1 event, or until the P6 Event, which is loss of the second element, with no mention of the time duration between the initial system condition and the event. The performance criteria for a P1 event can be met as long as it does not contemplate another event that would change the event to a P6 event. However, a P6 event is a TPL-003-0 Category C event which must contemplate a second contingency after the first. The existing TPL standards accomplished this with footnote b) in the Tables for all of the TPL standards, allowing system adjustments including curtailment of contracted firm transfers to prepare for the next contingency. Since FERC clearly states that this is not a requirement under TPL-002-0, but that it is addressed in TPL-003-0, they directed the ERO to modify the footnote for TPL-002-0. In TPL-003-0 the Category C3 event refers to a "Category B contingency, manual system adjustments, followed by another Category B contingency", however since the footnote for Category B contained the "To prepare for the next contingency?." language, and it is contained in the Table for TPL-003-0, that language must apply to the C3 event. Further, in Order 693, on TPL-003-0, FERC (1) did not direct the ERO to modify the same footnote which is contained in TPL-003-0, (2) recognizes that these are low probability events, and (3) stated that it "does not intend to recommend action on this issue [the appropriateness and value of including the ability of the system to withstand two simultaneous Category B contingencies for major load pockets] at

Organization	Question 11:	Question 11 Comments:
		this time and, instead, directs the ERO to consider the comments in possible future revisions to the Reliability Standard.? The SDT has inappropriately applied the direction of FERC on TPL-002-0 to the P6 event (which is similar to TPL-003-0 C3) without regard to its implications on the industry, the ratepayers, or even its own standards, as the impact of the team's interpretation would require changes in the methods of determining TTC's, ATC's, and SOL's. The additional costs (both monetary and intangible) incurred by ratepayers for no gain in the ability to transfer firm electric power, far outweigh any gain in reliability benefits for these low probability events. Just to provide one example to illustrate this point, if the SDT's current interpretation for a P6 event is not modified, FPL would have to spend in excess of $ 1 Billion dollars, in order to meet this performance criteria for 500 kV facilities, for an event with a probability of less than 0.07 per hundred mile-years (based on FPL's 500 kV facilities), which would be passed on to its ratepayers. There are many other examples on the FPL system, as well as other systems. This interpretation is fatally flawed and makes no sense from a reliability or cost perspective, not to mention the intangible impacts of siting, right-of-way acquisition, EMF, NIMBY, etc. Further, assuming the SDT interpretation, how could one justify the need before state commissions, and exercise eminent domain in the courts to take someone's land for right-of-way, a process that could take as long as 8-10 years, for minimal increase in reliability, and no increase in transfer capability. In order to assist the SDT, these paragraphs are included with references to FERC Order 693, to show that it has misinterpreted Order 693. The following captions stated below should help clarify this point. Order 693 states: P.1788 ?Under TPL-002-0 the system is not required to be able to withstand another N-1 contingency. That N-1 requirement is a Category C contingency which is addressed by TPL-003-0.? Therefore, the end state of P1 is not a ?secure? state, but a ?normal operating state?, as stated in P. 1796 ?The Commission, therefore, directs the ERO to modify the second sentence of footnote (b) to clarify that manual system adjustments other than shedding of firm load or curtailment of firm transfers are permitted to return the system to a normal operating state after the first contingency, provided these adjustment can be accomplished within the time period allowed by the short term or emergency ratings.? These two determinations by FERC together show that their interpretation of normal operating state is not the secure, ready for the next contingency state, rather, it is the state in which the performance criteria have been met for that planning event. With regard to the FERC direction of Order 693 on TPL-003 and ?the appropriateness and value of including the ability of the system to withstand two simultaneous Category B contingencies for major load pockets?, FERC states in P. 1824, ?Many commenters indicated that this was a very low probability event and the costs for addressing such an event would be significant. As a result, EEI states that a dialogue must first be initiated within the industry and with state public utility commissions to identify such load pockets, to target the required potentially significant transmission investments and to develop plans for allocating the costs of such investments. In light of these comments, the Commission does not intend to recommend action on this issue at this time and, instead, directs the ERO to consider the comments in possible future revisions to the Reliability Standard.?FPL agrees with the increased performance requirement for the P3 multiple contingency event that assumes the loss of a generator as the first contingency. Firm transfers should not depend upon specific generators being on line, however firm transfers must depend upon transmission lines being in-service.
SERC Dynamics	Yes	The changes are more practical. If two or more 500kV lines are lost, it makes complete sense to allow loss of non-consequential load so long as cascading outages are not triggered. While we agree interruption of firm transmission service

Organization	Question 11:	Question 11 Comments:
Review Subcommittee		and non-consequential load loss should not be allowed to meet the planning requirements for the first system contingency (defined as initial system condition in the table), these system adjustments should be allowed to prepare for the second event so that the system will meet the requirements following the second event. We recommend that clarifying changes be made to incorporate this concept. We recommend that the statement above be included as modification or as a footnote for the P6 portion of the table as follows:Foot note: Interruption of firm transmission service and non-consequential load loss should be allowed after the first event as a system adjustment to prepare for the second event and meet the requirements following the second event.See our related response to question 15.
Southern Company Transmission	Yes and No	The requirements are more practical now. If two or more 500kV lines are lost, it makes complete sense to allow loss of non-consequential load so long as cascading outages are not triggered. While we agree interruption of firm transmission service and non-consequential load loss should not be allowed to meet the planning requirements for the first system contingency (to get loadings back within normal ratings), these system adjustments should be allowed to prepare for the second event so that the system will meet the requirements following the second event. We recommend that clarifying changes be made to incorporate this concept. We recommend that the statement below be included as modification or as a footnote for the P6 portion of the table as follows: Interruption of firm transmission service and non-consequential load loss are allowed after the first event as a system adjustment to prepare for the second event in order to meet the requirements following the second event.
Duke Energy	Yes	The changes are more practical. If two or more 500kV lines are lost, it makes complete sense to allow loss of non-consequential load so long as cascading outages are not triggered.? While we agree interruption of firm transmission service and non-consequential load loss should not be allowed to meet the planning requirements for the first system contingency (defined as initial system condition in the table), these system adjustments should be allowed to prepare for the second event so that the system will meet the requirements following the second event.? We recommend that clarifying changes be made to incorporate this concept. We recommend that the statement above be included as a modification or as a footnote for the P6 portion of the Steady State and Stability tables as follows: "For P6 multiple contingency events, Transmission configuration changes and redispatch of generation are allowed provided that all Facilities shall be operating within their Facility Ratings and within their thermal and voltage limits. Permissible Transmission configuration changes include dropping of load and firm transfers needed to prepare for the second contingency. See our related response to question 15.
SERC Reliability Review Subcommittee and Planning Standards	Yes	Since Event P6 is essentially a sub-set of the existing Category C.3 Contingency events, we support these modifications which make the system performance requirements for P6 consistent with what exist today for Category C.3. While we agree interruption of firm transmission service and non-consequential load loss should not be allowed to meet the planning requirements for the first system contingency, these system adjustments should be allowed to prepare for the second event so that the system will meet the requirements following the second event. We recommend that clarifying changes be made to incorporate this concept. We recommend that the statement below be included as modification or as a footnote for the P6 portion of the table as follows: Interruption of firm transmission service and non-consequential load loss are allowed after the

Organization	Question 11:	Question 11 Comments:
Subcommittee		first event as a system adjustment to prepare for the second event in order to meet the requirements following the second event.
Orlando Utilities Commission	Yes and No	As written the standard does not seem to forbid the adjustment of firm transfers and non-consequential load in preparation for the second part of an N-1-1, however that conflicts with the teams statements on the recent national call. If the intent is to forbid the adjustment of firm transfers and non-consequential load in preparation for the second part of an n-1-1 that needs to be made explicitly clear in the standard. This is especially important since one of the current understandings of the standards relating to Transmission Planning and System Operating Limits clearly allow such adjustments, and to not make it clear is building a compliance trap for the unwary. While I do not support the creation of this n-1-1 threshold if it is going to be established it needs to be abundantly clear.
Entergy Services, Inc.	Yes and No	Since Event P6 is essentially a sub-set of the existing Category C.3 Contingency events, we support these modifications which make the system performance requirements for P6 consistent with what exist today for Category C.3.While we agree interruption of firm transmission service and non-consequential load loss should not be allowed to meet the planning requirements for the first system contingency (to get loadings back within normal ratings), these system adjustments should be allowed to prepare for the second event so that the system will meet the requirements following the second event. We recommend that clarifying changes be made to incorporate this concept. We recommend that the statement below be included as modification or as a footnote for the P6 portion of the table as follows: Interruption of firm transmission service and non-consequential load loss are allowed after the first event as a system adjustment to prepare for the second event in order to meet the requirements following the second event. As the requirement is now implemented in the table, transmission service would need to be made available only if they can be accommodated for N-2 events. This would place these services on equal footing from a reliability perspective but would virtually eliminate the firm transmission market.
Response: Footnote #10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for Event P1. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted Interruptible Loads, in preparation for the next Contingency. Nonetheless, the SDT has provided an exception (R2.6.4) to address those situations, which may arise that are beyond the control of the Transmission Planner or Planning Coordinator, and, which can prevent the implementation of the relevant Corrective Action Plan in the required timeframe. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
Transmission	Yes	We agree with revising P6 to permit loss of Non-Consequential Load to meet performance requirements for Systems above

Organization	Question 11:	Question 11 Comments:
Agency of Northern California		300kV. However, we are concerned that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers would not be allowed as part of system adjustment in preparation for the next N-1. Allowing curtailment of transmission service or firm transfers for such system adjustments should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1, or transmission facilities, which would have otherwise been unnecessary, would have to be built. Either would adversely impact customers. We also have questions on Event P6 in both Performance Tables 1 and 2: We would like some clarification on the overlapping single contingencies as denoted in Event P6 (N-1-1), and one where a single contingency, say Event P1 (N-1), follows a prior "planned" outage of a Facility (N-1). The former would allow the Non-consequential Load Loss, while the latter would prohibit it.
Pacific Gas and Electric Co.	Yes	We agree with revising P6 to permit loss of Non-Consequential Load to meet performance requirements for Systems above 300kV. However, we are concerned that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers would not be allowed as part of system adjustment in preparation for the next N-1. Allowing curtailment of transmission service or firm transfers for such system adjustments should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1, or transmission facilities, which would have otherwise been unnecessary, would have to be built. Either would adversely impact customers. We also have questions on Event P6 in both Performance Tables 1 and 2: We would like some clarification on the overlapping single contingencies as denoted in Event P6 (N-1-1), and one where a single contingency, say Event P1 (N-1), follows a prior "planned" outage of a Facility (N-1). The former would allow the Non-consequential Load Loss, while the latter would prohibit it.
Public Service Company of New Mexico	Yes	We agree with revising P6 to permit loss of Non-Consequential Load to meet performance requirements for Systems above 300kV. However, we are concerned that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers would not be allowed as part of system adjustment in preparation for the next N-1. Allowing curtailment of transmission service or firm transfers for such system adjustments should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1, or transmission facilities, which would have otherwise been unnecessary, would have to be built. Either would adversely impact customers. We also have questions on Event P6 in both Performance Tables 1 and 2: We would like some clarification on the overlapping single contingencies as denoted in Event P6 (N-1-1), and one where a single contingency, say Event P1 (N-1), follows a prior "planned" outage of a Facility (N-1). The former would allow the Non-consequential Load Loss, while the latter would prohibit it.
Puget Sound Energy, Inc.	Yes	We agree with revising P6 to permit loss of Non-Consequential Load to meet performance requirements for Systems above 300 kV. However, we are concerned that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers would not be allowed as part of system adjustment in preparation for the next N-1. Allowing curtailment of transmission service or firm transfers for such system adjustments should be added to R3.3.2.2. Otherwise, the power

The former would allow the Non-consequential Load Loss, while the latter would prohibit it.
BPA Transmission	Yes and No	We agree with the revision to permit the loss of Non-Consequential Load to meet performance requirements for Systems above 300 kV. However, a better definition is needed for "system adjustments". For example, are curtailments permitted as

Organization	Question 11:	Question 11 Comments:
Reliability Program		part of "system adjustments"? Within category P6, there needs to be a common reason for the overlapping outage to occur, such as lines on a common tower, and the appropriate reasons need to be clearly identified in the requirements. In general, we believe that performance category P6 should be part of the Operating Standards rather than the Planning Standards. For these types of events, it is the responsibility of Operations to determine the necessary system adjustments to prepare for the next contingency within the operating horizon prior to year one as defined in the Planning Standards. Therefore, the performance requirements for this category of contingencies, do not belong in the Planning Standards.
Response: Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. Regarding the difference between overlapping single Contingencies as denoted in Event P6 (N-1-1), and one where a single Contingency, say Event P1 (N-1), follows a prior "planned" outage of a Facility (i.e., N-1), the difference would be whether the prior outage was planned (such as maintenance) or anticipated (such as extended outage). If the Prior outage is planned or anticipated, then the next N-1 is a P1 Event, otherwise, it is a P6 Event.		
Progress Energy Florida, Inc.	No	PEF is pleased that between the 1st and 2nd drafts, the "no" was changed to "yes" concerning allowance of curtailment of Firm Transmission Service or curtailment of Non-Consequential Load for Event P6. PEF has significant concerns, however, regarding the issue of "System Adjustments" associated with P6 and P6's direct association with P1, and thus must check "no" on this Question despite the improvements that have been made. A major misstep has been made with regard to development of P6. Every P1 event is by default the first half of a P6 event. Given that fact, PEF sees several concerns with this issue. First, for P1 events, neither curtailment of Firm Transmission Service nor curtailment of Non-Consequential Load are allowed, regardless of voltage. Both are allowed, however, for a P6 event. In order for the two events to not contradict each other, the conclusion that must be reached is that curtailment of Firm Transmission Service and curtailment of Non-Consequential Load are not allowed as part of System Adjustments, i.e. they are not allowed in between the two steps of P6, only after the 2nd step of P6 (Note: this is not clear partly due to the fact that the term "System Adjustments" is not defined anywhere in the Standard, and PEF therefore requests that the SDT define the term, and that the term should include the allowance of curtailment of Firm Transmission Service and the loss of Non-Consequential Load). PEF has two very serious concerns with that conclusion: a) FERC in its Order 693 stated that the BES is not required to have to withstand another N-1 contingency. Specifically, in Paragraph 1788 of Order 693 FERC states that ?Under TPL-002-0 the system is not required to be able to withstand another N-1 contingency. That N-1 requirement is a Category C contingency which is addressed by TPL-003-0.? Thus FERC clearly made a distinction between N-1 events for which a 2nd N-1 event never happens and N-1-1 events. The SDT, however, has

Organization	Question 11:	Question 11 Comments:
		not written the draft TPL Standard in such a way that Transmission Owners can reasonably and fairly plan for the 2nd N-1 event as TPL-003-0 has done. b) PEF has several 1st N-1 events on their 500 kV system for which "System Adjustments" are necessarily going to have to include either the curtailment of Firm Transmission Service or the curtailment of Non-Consequential Load in order to prepare for the 2nd N-1 event. The draft TPL Standard, while far from definitive on this matter, appears to allow neither as part of System Adjustments. PEF will thus be forced to i) construct redundant 500 kV facilities, at a cost to our ratepayers that will doubtless run into the range of billions of dollars, or ii) significantly reduce the posted levels of ATC/TTC of the various transmission paths available. Option (ii) is not a better option than option (i), for two main reasons: reducing ATC/TTC essentially puts marketing entities out of business, and forces utilities to build more generation sites to compensate for the loss of energy brought in using the previously higher ATC values. Either option results in prohibitively high costs to be passed on to the ratepayers for no measurable increase in BES reliability. This discussion also brings up additional concerns that include the lack of consideration of State government jurisdiction, the lack of public involvement, and ultimately, the lack of sufficient reason to construct such redundancy. PEF has never had a 500 kV N-1-1 event on its system. For this draft Standard to require redundancy projects costing billions of dollars for events that to date have never occurred is preposterous (note: additional comments concerning public outreach, no State government involvement, etc., are contained in the response to Question 15).
Response: Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for a single Contingency Event. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted Interruptible Loads, in preparation for the next Contingency. Header note 'e' provides the System adjustments allowed after a first Contingency Event. **Header note 'e'** -- For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
Ameren	No	Please clarify that the shunt devices to be considered for outage are those that are directly connected to the transmission system. For the P6 events involving a transmission facility and a shunt device, local voltage instability issues may result in dropping of load in the vicinity of the outaged facilities, but the concern should be that the load dropped is not wide-spread. The words "Voltage instability" should be removed from Header Note 3 of Table 1 so that it becomes "Cascading outages and uncontrolled islanding shall not occur."

Organization	Question 11:	Question 11 Comments:
Response: Requirement R3.3.3 (now Requirement R3.4) was modified to allow the PC and TP to determine the single and multiple Contingencies to be included in the planning analyses. This would give the TP and the PC the discretion to study the Contingency most suited to the study area. **R3.4** Those Planning Event Contingencies in Table 1 ~~– Steady State Performance not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~includee an explanation of why the remaining Contingencies would produce less severe System results. However, "voltage instability" has not been removed from the Header Note 3 (now Note a) because voltage instability in a local area can spread to the rest of the System if not arrested in time, and a planning analysis is needed to ascertain if there is a voltage stability problem, and, if so, the corrective actions needed.		
Exelon Transmission Planning	No	We do not agree that the requirement should be so much more severe for an internal breaker fault as opposed to two single line outages for elements over 300 kV.
Response: An internal breaker fault is a single event covered in FERC Order 693. In addition, an internal breaker fault would remove from service all Facilities connecting to the faulted breaker simultaneously, which would likely be more severe than the outage of two single lines.		
MidAmerican Energy Company	No	MEC suggests that there be more explanation of what system adjustments are permitted. There should be some specific limit like 100MW below which load loss is allowed. Otherwise, very high cost solutions will be required for very low probability events.
MRO NERC Standards Review Subcommittee	No	The MRO suggests that there be more explanation of what system adjustments are permitted. There should be some specific limit like 100MW below which load loss is allowed. Otherwise, very high cost solutions will be required for very low probability events.
Response: Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. While the SDT does not disagree with having some specific limits below which load loss would be allowed, arriving at such an amount may be too case-specific and too descriptive for a Continent-wide Standard. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		

Organization	Question 11:	Question 11 Comments:
Austin Energy	No	It should be left to the Transmission Planner and/or Planning Coordinator (ISO or RTO) to select the credible multiple contingencies to be studied as planning events. Therefore P6 should be deleted.
Brazos Electric Power Cooperative, Inc.	No	P6 should be incorporated back into P5. Up to this point, studying all shunt devices has not been considered to have a significant impact on the BES. In addition these are picked up when studying other contingencies. Certain type devices should be reviewed individually, FACTS devices, etc? but this should be at the discretion of the TP or PC. Currently adding shunt devices as a category would require modification to case data or software to be able to automatically run through them all and we are not convinced this is worth the effort.
Response: Requirement R3.3.3 (now Requirement R3.4) was modified to allow the PC and TP to determine the single and multiple Contingencies to be included in the planning analyses. This would give the TP and the PC the discretion to study the Contingency most suited to the study area, and can choose not to study P6 Events if they are less severe than the Events studied. Therefore, P6 is not deleted. **R3.4** Those Planning Event Contingencies in Table 1 ~~– Steady State Performance~~ ~~not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.		
AEP	Yes	Table 1 does not specify a maximum amount of allowable non-consequential load loss for those categories (including P6) that have a "Yes" listed under the "Non-Consequential Load Loss Allowed" (last) column. See load loss definition under Attachment D of PJM Manual 14B for an example of a maximum amount specification.
Response: While the SDT does not disagree with having some specific maximum amount of allowable Non-Consequential Load loss for these events, arriving at such an amount may be too case-specific and too descriptive for a Continent-wide Standard		
ERCOT System Planning	No	The former P5 of the first draft only required transmission circuits of 300 kV and above to be simulated out of service followed by loss of transmission circuit or transformer. P6 of the second draft requires all BES (100 kV and above) transmission circuits, transformers, dc lines, and shunt devices in combination of another BES circuit, transformer, dc line, and shunt device. The number of contingencies that have to be simulated increased dramatically to an impractical level and would require days of uninterrupted computer run time to complete. This, in combination with other contingencies and sensitivities required in this draft of the standard, is not feasible for large entities. ERCOT recommends that this planning event P6 retain the verbiage regarding transmission lines and transformer low side windings above 300kV.
Response: The previous draft P5 set requirements for N-1-1 300 kV and above; P8 sets requirements for N-1-1 below 300 kV. P6 in this draft combines both P5 and P8 from the previous draft. So, the work load for both drafts would be the same. In addition, Requirement R3.3.3 (now Requirement R3.4) was modified to allow the PC and TP to determine the single and multiple Contingencies to be included in the planning analyses. This would give the TP and the PC the discretion

<tr><td>American Transmission Company</td><td>Yes</td><td>We suggest that there be more explanation of what system adjustments are permitted. We understand that the revised P6 allows loss of Non-Consequential Load for Systems below 300 kV as well.</td></tr>
<tr><td colspan="3">**Response:** Header note ‘e’ provides the System adjustments allowed after a first Contingency Event. In addition, Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of firm Transmission Service will be allowed in preparation for the next Contingency.

Header note ‘e’ -- For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled ‘Initial System Conditions’) and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner’s planning region are relied upon, Facility Ratings in those regions must be considered.</td></tr>
<tr><td>Florida Reliability Coordinating Council, inc</td><td>No</td><td>For P6 events (and all other events that allow system adjustments after the loss of a transmission device), this draft does not clearly define when the requirements in the columns marked as ?Interruption of Firm Transmission Service? or ?Non-consequential Load Loss Allowed? apply. The SDT should clearly state that the requirements in these columns are only applicable after the Event occurs from the Initial System Condition. In addition, the SDT should make it clear whether Interruption of Firm Transmission Service and Non-consequential Load Loss is allowed in preparation for the 2nd Event. On the NERC conference call for the 2nd draft, the SDT chair indicated that Interruption of Firm Transmission Service and Non-consequential Load Loss is not acceptable in preparation for the next event. In Order 693, Para. 1788 - Para. 1796, FERC distinguished between ?preparing for the next contingency? and returning to a system normal state. The SDT removed the allowance that was made in footnote c of TPL-003-0 to ?To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.? (emphasis added) for Category C3 events (now P6 for facilities greater than 300kV). This change in the standard is not directed by the FERC Order 693 and is not a reliability improvement that is cost justified. Forced outage rates for equipment greater than 300kV is very low and the impact on markets is very large. Many utilities have granted long term transmission service to entities with the expectation that the service can be curtailed if required in preparation for the next event. If this is not allowed, entities</td></tr>
</table>

Organization	Question 11:	Question 11 Comments:
		within FRCC will have to greatly reduce the long term firm imports into FRCC or construct additional EHV transmission lines from a location well into Georgia down to a point in the southeastern portion of FRCC. While an in-depth cost has not been completed for a project of this size in many years, it is reasonable to expect that a cost in excess of $1.5 - $2.0 Billion. This investment will only slightly increase the amount of firm imports into FRCC (and replace the imports allowed before this change) for an event that may only occur only once every 20+ years. If this event happens, the Transmission Owners will re-dispatch their own generation to curtail their transactions in addition to curtailing the firm transmission service of others, per their OATT. The SDT should clearly state for these Planning Events, all system adjustments including Interruption of Firm Transmission Service and Non-consequential Load Loss is acceptable in preparation for the second Event where system adjustments are allowed between events.
Response: The SDT believes that Table 1 is clear that the events occur from P0 as the starting condition. Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for event P1. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted Interruptible Loads, in preparation for the next Contingency. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
FirstEnergy Corp.	Yes	We agree with the change that now permits the loss of Non-Consequential Load for N-1-1 to meet performance requirements regardless of the voltage level studied. It is well understood that following a single contingency (N-1) that no Non-Consequential Load loss or interruption of Firm Transmission service is permitted. The SDT needs to clarify for industry if interruption of Firm Transfers is permitted pre-contingency to prepare for the 2nd (over-lapping) contingency. This is presently permissible in the existing TPL standards as Table 1 footnote 'b' reads ?? To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.?
Response: Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings

Los Angeles Department of Water and Power	Yes	yes, only because there is no discrimination among different and arbitrary voltage classes.
IESO	Yes	We concur with the need to test N-1-1 contingencies involving transmission facilities allowing interruptions to firm transmission services and non-consequential load loss to meet performance requirements, for any voltage levels as long as adverse reliability impacts on the BES are exhibited.
Response: Thank you for your response.		

12. Comments from some entities received from the posting of the 1st draft standard indicated that significant additional costs will be required to meet the proposed requirements and performance tables. Commenters also indicated that it would take several years to install the additional facilities needed to meet the change in requirements. The SDT has attempted to adjust and clarify the proposed requirements and performance in light of these initial comments; however, the SDT needs more specific information on these concerns so that it can put the proposed requirements in perspective and make more adjustments as appropriate. Questions 12, 13 & 14 address these concerns.

What do you estimate will be your additional approximate costs, if any, to support the proposed requirements and performance tables over and above what you are currently doing for the following: Analysis:

One time cost to supplement past study portfolio and analyze the supplemental studies (depending on the extent of supplemental work needed, this may be an accumulated cost over more than one year):

How many years do you estimate that it will take to complete supplemental studies and associated analysis?

On-going additional cost for expanded studies and analysis:

Summary Consideration:

The SDT has reviewed the responses and will use the data as background information in making any further decisions with regard to this standard. No direct changes were made to any of the requirements at this time based on this information.

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
Dominion - Electric Transmission Planning	It is extremely difficult, if not impossible, to accurately determine the costs required to perform supplemental studies in order to become compliant with these proposed standards. It will take time to just become familiar with the proposed changes as well as developing the necessary documentation to show compliance. What is obvious is that increased staffing levels will be required to perform the assessments. Furthermore, it will take significant time to become fully compliant. Therefore, a grace	As stated above, this is difficult to predict but a grace period of 2 to 3 years should be considered.	At this point we are estimating at least 2 to 3 additional resources may be required to perform the additional studies on an ongoing basis. For Dominion, three (3) additional engineers to perform this analysis is approximately $500,000 per year (including benefits and overheads).

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	period of 2 to 3 years should be granted in order to perform the required assessments and become compliant.		
NPCC	NPCC Participating Members believe some additional cost for analysis and study may be required in order to meet the final requirements of the standard and the associated performance tables. However, the ability to accurately estimate the costs of these studies, how long the analysis may take and how much additional effort may need to be made to compile the documentation is not possible at this time. Many believe posing this question is premature and cannot be quantified at this time, and it may hold questionable value without a better understanding of the complete final requirements of the standard. Many believed that the sensitivity language, although currently being performed to some extent within NPCC, that now appears in the standard, could have a drastic effect on the extent to which this additional analysis is conducted and the associated costs.		
TVA System Planning	One component of these costs is based on modification to the load flow database. A massive effort would need to be undertaken to model bus sections and breaker codes in order to simulate the planning events needed to stay current with the proposed standards. Also, man-power to perform the extra analysis was considered. Additional man-power of 5 engineers (2 years) would	The majority of the time would be spent modifying the load flow database so that the new planning event simulations could be analyzed. ? Time duration estimate of 2 years would be required.	Additional man-power of 4 engineers at costs of $400,000 per year would be required.

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	be required at cost of $1,000,000		
Progress Energy Carolinas	$150,000	3 Years	$50,000/year
BCTC	We estimate an initial one time cost of up to $50,000 for BCTC planners to become familiar with the new format and requirements of the standards and make changes to their assessment process. In addition, additional study costs for sensitivity studies (many stability studies) may cost an additional $50,000. Many segments of the BCTC system are stability limited and we have significant experience with the needs and timelines for doing stability studies. Stability studies identify the need for RAS for multiple contingencies, which is fairly short lead time. We are currently satisfied with the amount of stability studies we do for the near and long term planning horizons. We do not need to do sensitivity studies. We do not expect any significant additional costs for studying Extreme Events because most of the wide area events listed are not applicable to the BCTC system.	1 Year	The additional cost could be from $50,000 to $100,000 per year. We will incur additional study costs for sensitivity studies and expect additional planning administration costs for reconciling between reinforcements required to meet the CLL/NCLL definitions and P3 requirements vs. what we actually propose as doable projects.
Manitoba Hydro	$500,000	2 to 3 person years years	$300,000
Los Angeles Department of Water and Power	I do not object to added studies serving useful purposes; however, duplicative studies are a waste of resources. Mixing operating studies and requiring such studies in the planning of future system shows a confused perspective on the	Please be more specific as to what additional studies are being referred here.

	purpose of planning studies verses operating studies.		
National Grid	The comment period was not long enough to develop a thoughtful response to the impact that the new standards might have. Therefore costs can be speculated to be incrementally hundreds of thousands per year.	The comment period was not long enough to develop a thoughtful response to the impact that the new standards might have on the planning studies, but a very rough thought would be that any additional needs would be captured within the normal planning studies, which would likely occur within two study cycles of the effective date of the standard.	If the new requirements are included in the normal study cycle and the costs are the incremental costs required by additional study requirements, then the annual costs will be less than the first year costs, but we still will need additional staffing, which will cost hundreds of thousands per year. In addition to cost, there is a significant concern over whether or not the labor market can provide enough qualified staff to complete the required work.
Pacific Gas and Electric Co.	We expect supplemental studies to be needed for the entire 500 kV system and most of the 230 kV system. We estimate the one time cost for supplemental studies to be around $100,000.	Assuming that the supplemental studies would be added to the on-going work, we estimate the time to complete the supplemental studies to be about 2 to 3 years.	We estimate that the additional cost for the expanded studies and analysis would be about $50,000/year.
Gainesville Regional Utilities	$50,000. I don't feel this is needed for smaller utilities.	3 years. Again, I don't feel this is needed for smaller utilities.	$60,000. Again, I don't feel this is needed for smaller utilities.

	the standard, could have a drastic affect on the extent to which this additional analysis is conducted and the associated costs		
Progress Energy Florida, Inc.	Given that a) PEF has never performed analysis to the extent that the draft TPL Standard is requiring and b) the draft is going through an iterative process and is at present considered a "moving target", a reasonably accurate estimate, or even a wild guess, cannot be provided for this answer. Having said that, it can be reasonably said that any estimate that could safely claim a reasonable degree of accuracy would require analysis performed full-time by several individuals over a period of several months (or possibly a period greater than one year). Just the cost of the assessment analysis alone would present an O&M challenge to PEF's Transmission department.	PEF has assessed this question and determined that any period of time less than 10 years would be inadequate to assess the supplemental nature of the requirements of the draft TPL Standard, to say nothing of the time required to construct the required facilities.	PEF, again stating that this cannot be considered an accurate estimate for the reasons stated in 12a, would estimate the burdened labor cost to perform such supplemental analysis on an ongoing basis to be at least $1M annually.
Sierra Pacific Power Comapny / Nevada Power Company	$400,000	2 Man Years	$250,000/year
Lafayette Utilities System	Lafayette has not analyzed in any detail the resource requirements addressed in this question. Based on available information, we estimate that supplementing existing studies would require at least 1 FTE familiar with stability analysis to be able to complete this portion of TPL. The new steady-state analysis will require the addition of 1 FTE to be able to complete the additional P5-P7	See response to part 1 of Question 12.	See response to part 1 of Question 12.

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	requirements. These will be ongoing expenses whether accomplished by hiring new staff or relying on external service providers.		
Arizona Public Service Co.	Two person-year.	2-years.	one person year.
Ameren	One component of cost is to model in more detail all straight busses and bus-tie breakers at all transmission voltage levels. Contingency scenarios would also need to be developed and/or modified to correspond with the new powerflow models. The sensitivities presently specified will greatly increase the cost and time needed for updating all plant stability studies.	One-time costs to provide additional modeling detail and modify and test the revised contingency lists would be approximately 1 man-month or about $8000. Updating all plant stability studies would take approximately 5 man-years, at an estimated cost of approximately $500,000 (including benefits). Given existing regional requirements to complete the annual assessment by July 1 of the calendar year, additional staffing would likely be needed to complete this work, unless compliance were phased in over a number of years, similar to the MOD-024 and MOD-025 standards with respect to generator testing.	A review of the studies required for R2.1 indicates that at least 6 powerflow modeling scenarios would need to be completed to cover the base cases and sensitivities, which would be a 50% increase in the amount of work presently performed to meet the existing TPL-001 through 004 requirements for the near-term assessment. A review of the studies required for R2.4 indicates that at least 4 stability scenario models would need to be completed, which would be a 100% increase in the amount of work presently performed. Our present compliance performance and analyses activities take approximately 30 man-months to complete. We would expect the additional study analyses to add an additional 20 man-months of work and require 4-5 additional engineers at an annual cost of $400,000 to $500,000 (including benefits), given the regional requirement to complete the annual assessment by July 1.
City of Tallahassee, FL	we estimate a cost of $100,000 minimum since the City would likely have to outsource some of this analysis in addition to the work done by in-house system	hard to give a good estimate since the full ramifications of the required studies is not clear in the current draft. I would estimate 2 years at least.	similar costs to what was estimated above for the supplemental study cost, since staffing level is such that much of this ongoing work will likely be outsourced.

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	planning staff.		
Florida Power and Light	These costs cannot be determined without having experience with the new standard and its analysis requirements. Analysis of existing studies will undoubtedly uncover substantial additional study that would need to be performed, but the costs of such analysis and studies could not be reasonably estimated beyond stating that the costs would be significant resulting from 1000's of man-hours spent on supplemental work that would only determine if we were in compliance, not including any work necessary to determine what would be necessary to bring deficiencies in to compliance.	It would not be unreasonable to find that it takes one full planning horizon (10 years) to complete supplemental studies and analysis for the draft standard, because it is so prescriptive. Requirements such as R2.2.1 that requires that the planning assessment be extended for longer lead time projects (such as the multiple new nuclear projects being considered across the U.S.) and R2.4.1 that specifies "...including the behavior of induction motor loads" will likely invalidate past studies that took considerable time to perform and would have to be reproduced with the newly required considerations. Requirements such as R2.6 (and subrequirenments) invalidate many existing studies, because of subjective terms such as "material changes" and "would impact the study area" without definitions of "material" or "impact". Re-analyzing all existing studies and re-writing the results and conclusions using the new terminology (P0, P1, P5 etc. instead of Category A, B or C2, C3, C5 etc.) used in the new performance tables will also add substantially to the effort needed to insure compliance and make the information auditable.	$ 5 million dollars annually is perhaps very conservative.
CenterPoint Energy and CPS Energy	We have no analysis to support an answer to this question, and we believe any such analysis would be speculative. We believe the reality of the situation is that the requirements are not practically achievable	3-4 years, assuming reasonably practical interpretation of the impractical requirements.	

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	at any cost, so the ultimate cost would depend on practical interpretations of impractical requirements. Even if the cost could be reasonably estimated, we oppose detracting valuable expertise away from necessary, value-added analyses to unnecessary, over-reaching theoretical analyses and documentation for audit purposes.		
SRP	The additional study work associated with this Standard could cost up to SRP $100k.	1 to 2 years to complete these additional studies.	Estimate addition on-going costs of $50k.
MidAmerican Energy Company	MEC estimates that the total cost for one-time software licenses would be about $100,000.	MEC estimates that the lead time to perform supplemental studies and analyses to meet the new requirements would be 2 years.	MEC estimates that the on-going additional cost of expanded studies and analyses to meet the new requirements would be about $150,000 to $200,000 for additional staff and continuing software fees.
Tucson Electric Power Company	$200,000	6 month study performed by consultant	1 man-year
SERC Dynamics Review Subcommittee	The sensitivities will greatly increase the cost and time need for planning because the work is directly proportional to the number of sensitivities.		
MRO NERC Standards Review Subcommittee	The MRO estimates that the additional one-time costs of supplemental studies and analysis to meet the new requirements might be spread over five years because some analysis only has to be updated every five years. The MRO estimates that the total cost over five years for additional staff, consulting services, or software fees would be about $200,000 to $300,000 per	The MRO estimates that the lead time to perform supplemental studies and analysis to meet the new requirements would be up to 5 years.	The MRO estimates that the on-going additional cost of expanded studies and analysis to meet the new requirements would be about $150,000 to $200,000 for additional staff and continuing software fees per responsible entity.

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	responsible entity.		
Modesto Irrigation District	Unknown at this time.		
Midwest ISO	Some additional costs will be required to comply with all the requirements. This is difficult to quantify at this time.	This is difficult to quantify at this time, but any increased requirements should be clearly identified by the SDT and a transition period should be developed if the standards are intended to be more restrictive.	There will be an increase in ongoing cost for expanded studies and analysis. A transition period for staffing and process development will be required.
Tri-State Generation and Transmission Association, Inc.	Scenario assessments will significantly increase workload. Development of dynamic load models is ongoing, and will need a much longer implementation period than the steady state portions of the standard. As much as $500,000 may be required to address all of R2.1.3 scenario requirements.	It would take as much as two years for the initial supplemental studies with existing staff.	Ongoing additional sensitivity and dynamic studies would cost approximately $300,000 per year.
AEP	Additional one-time cost of 33 man-months	2 years	Additional ongoing cost of 12 man-months
Lakeland Electric	Unknown	Unknown	Unknown
Brazos Electric Power Cooperative, Inc.	We have no real way to estimate this or determine these costs.	Again, we have no real feel for making an estimate but it would be safe to say that the studies would take longer than the planning window. In other words, the results would not be completed before we would have to start them over again.	
NERC and Regional Coordination	Clarity about the exact number of supplemental studies required needs to be added to the standard before this question can bee addressed. The requirements		

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
	contained within the standard are nebulous. The requirements need to clearly state the depth of the studies required for each time horizon.		
ColumbiaGrid	The new TPL Standard raises the bar of transmission system performance. This can be expected to require significant additional analysis, documentation and system reinforcements (or reduced firm transfers allowed on the system if system reinforcements are not made). We will defer to our members to provide quantification of those elements.		
IESO	Minimal, if any, since the IESO has been conducting and documenting planning studies that meet events and performance criteria that are very similar to those specified in the draft TPL-001 standard. However, this is speculative at this time since we are not sure what the eventual standard will be like. Another uncertain area is the extent to which additional studies are required if sensitivity testing is mandated. Please see our comments under Q2 and Q10 on sensitivity testing. If sensitivity testing should become a requirement, then the scope is very wide and we are unable to have a good handle on the incremental time and cost to supplement past study portfolio.	Minimal, if any, for the reasons indicated above, other than for meeting the sensitivity testing requirements (if mandated) which cannot be quantified.	Minimal, if any, for the reasons indicated above, other than for meeting the sensitivity testing requirements (if mandated) which cannot be quantified.
Northeast Utilities	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations. Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
North Carolina Electric Membership Corp	N/A	N/A	N/A
ERCOT System Planning		At least 4 years. It will take as long as the largest entity in our system which has estimated about 4 years. We are totally dependent on them for all data needed for these studies.	he workload to support the existing TPL-001 to TPL-004 has already consumed two full-time senior positions. Add to that the new requirements for steady state studies necessary in this standard would take at least another full time position. The new stability study requirements and short circuit requirement added would double the number of people necessary for a total of approximately six full time positions with moderate to high experience levels. (Four incremental FTEs with estimated annual cost of $650,000). Purchasing additional licenses for study software is an additional expense.
American Transmission Company	We estimate that the additional one-time costs of supplemental studies and analyses to meet the new requirements might be spread over five years because some analysis only has to be updated every five years. So, we estimate that the total cost over five years for additional staff or consulting services may about $200,000 to $300,000.	We estimate that the lead time to perform supplemental studies and analyses to meet the new requirements might be up to 5 years.	We estimate that the on-going additional cost of expanded studies and analyses to meet the new requirements might be about $150,000 to $200,000 for additional staff.
New York Independent System Operator	A very preliminary estimate would be potentially millions of dollars.	Again, a very preliminary estimate would be two years.	Preliminary estimate is on the order of hundreds of thousands of dollars In addition to cost, there is a significant concern over whether or not there will be

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
			enough staff to complete the required work.
SERC Reliability Review Subcommittee and Planning Standards Subcommittee	One component of these costs is based on modification to the loadflow database. A massive effort would need to be undertaken to model bus sections and breaker codes in order to simulate the planning events needed to stay current with the new standards. Also, man-power to perform the extra analysis was considered. Additional man-power: 5 engineers (2 years) Cost: $1,000,000	The majority of the time would be spent modifying the loadflow database so that the new planning event simulations could be analyzed. Time: 2 years	Additional man-power: 4 engineers Costs: $400,000 / year The following analysis was performed by one large integrated utility in SERC. The results are not representative of all utilities in the SERC region, but would be multiplied many times over to fully represent the SERC region as a whole. A comprehensive study of the impact of these proposed and incomplete standards is not feasible until they are finalized. Regarding manpower, aside from the estimated costs there is the very real situation that the number of qualified engineers available in the industry is nowhere near what would be necessary to carry out the studies (including sensitivities) called for by the proposed standard. This reality needs to be taken into consideration by the Standards Drafting Team when it makes its implementation plan recommendations.
Oncor Electric Delivery	Cost to supplement past study portfolio would be between $250,000 to 750,000.	3 to 5 years with added resources (staff)	$500,000 annually
ISO New England Inc.	The comment period was not long enough to develop a thoughtful response to the impact that the new standards might have. Therefore cost can not be reasonably speculated.	The comment period was not long enough to develop a thoughtful response to the impact that the new standards might have on the planning studies, but a very rough thought would be that any additional needs would be captured within the normal planning studies, which would likely occur within two study cycles of the effective date of the standard.	The comment period was not long enough to develop a thoughtful response to the impact that the new standards might have on study effort and the associated cost. In addition to cost, there is a significant concern over whether or not there will be enough staff to complete the required work.

Organization	1 - Question 12 Comments:	2 - Question 12 Comments:	3 - Question 12 Comments:
Orlando Utilities Commission	$75,000 to supplement past study portfolio. (We have a fairly small system, only 1400 MW)	Two years, one year to recruit additional planner, the second to perform the baseline studies. This assumes there are sufficient trained personnel in the industry and they can be recruited.	$75,000 each year.
Entergy Services, Inc.	Cost will be covered by the on-going study costs as indicated below.	18 to 24 months	$1,200,000 / year
BPA Transmission Reliability Program	This information is not available.	This information is not available.	This information is not available.
Response: The SDT thanks all who responded to this survey question.			

13. **Documentation: One time cost to prepare reporting documentation associated with studies needed to supplement past study portfolio (depending on the time required to complete the supplemental work, this may be an accumulated cost over more than one year) – and on-going additional cost for documentation of expanded studies and analysis:**

Summary Consideration:

The SDT has reviewed the responses and will use the data as background information in making any further decisions with regard to this standard. No direct changes were made to any of the requirements at this time based on this information.

Organization	1 - Question 13 Comments:	2 - Question 13 Comments:
Dominion - Electric Transmission Planning	The initial process development and documentation will be the most difficult and time consuming portion. Dominion - Electric Transmission recommends a period of 3 to 5 years be given for this initial period of becoming compliant and preparing the documentation. As noted above, it is difficult to provide cost estimates, but we expect at least 2 to 3 additional resources will be required, at a minimum.	See response above.
NPCC	See above	
TVA System Planning	Additional man-power of 1 engineer (1 year) would be required at cost of $100,000	Additional man-power of 1 engineer at costs of $100,000 / year
Progress Energy Carolinas	$60,000	$20,000/year
BCTC	Included in the above. We do not do analysis without documentation.	Included in the above. We do not do studies without documenting them
Manitoba Hydro	$200,000	$100,000
Los Angeles Department of Water and Power	This assumes that past studies are inadequate and supplemental studies are needed. The standard does add a lot of duplicative and unnecessary operating scenarios that are already required	

Organization	1 - Question 13 Comments:	2 - Question 13 Comments:
	under TOP and MOD; but they should be deleted because they serve no useful purpose under TPL, why even spend an extra penny if it is for naught.	
National Grid	See response to question 12.	See response to question 12.
Pacific Gas and Electric Co.	This cost would be included in the cost of performing the supplemental studies.	This cost would be included in the cost of performing the expanded studies and analysis
Gainesville Regional Utilities	Probably would be covered in the previously provided annual cost. Again, I don't feel this is needed for smaller utilities.	Probably would be covered in the previously provided annual cost. Again, I don't feel this is needed for smaller utilities.
JEA	Included in Question 12 estimates.	Included in Question 12 estimates.
PacifiCorp	$250,000 over two years	$125,00
Puget Sound Energy, Inc.	$150,000 for the STD in its current form.	$50,000
ITC Holdings: ITC, METC, ITC Midwest	While we recognize that the standards might require us to garner a little more manpower and will take a little more time, we believe that running these studies is important.	While we recognize that the standards might require us to garner a little more manpower and will take a little more time, we believe that running these studies is important.
Idaho Power Company	Appx $50k	Appx $50k
Hydro-Quebec TransEnergie (HQT)	See Q12	
Progress Energy Florida, Inc.	Again, these costs cannot be reasonably estimated given the difficulties stated in the answer to Question 12a. It would reasonable to expect that the number of individuals in PEF's Transmission Planning group would have to dramatically increase, at least doubling in size or possibly significantly more	Documentation cannot be separated from the actual analysis itself, and thus would be included as part of the $1M estimate stated in the answer to Question 12b above.

Organization	1 - Question 13 Comments:	2 - Question 13 Comments:
	than doubling.	
Sierra Pacific Power Comapny / Nevada Power Company	$100,000	$50,000

Arizona Public Service Co.	$200,000.00	$100,000.00
Ameren	Documentation preparation to include the short-circuit assessment, the amount of consequential load dropped for single contingencies, the expanded requirements of the Corrective Action Plan, and how the sensitivities affect the Corrective Action Plan would take a man-week or two at most (no significant cost increase or manpower increase).	Our present documentation activities to develop the assessment and the corrective action plan take approximately 2 man-months to complete. We would expect the documentation to cover the additional study analyses to add an additional 2 man-months of work. The additional documentation for the Consequential Load Loss, short-circuit analysis, expanded requirements of the Corrective Action Plan, and documentation of how the sensitivities studied affect the corrective plan are estimated to double the existing reporting requirements, resulting in an increase of 3.5 man-months and require 2 additional engineers at an annual cost of $200,000 (including benefits), given the regional requirement to complete the assessment by July 1.
City of Tallahassee, FL	documentation cost was included in the cost estimates for #12, since development of the documentation is part of the study work scope.	
Florida Power and Light	These costs cannot be determined without having experience with the new standard and its documentation requirements. Analysis of existing studies will undoubtedly uncover substantial additional documentation that would need to be produced, but the costs of such document production could not be reasonably estimated beyond stating that the costs would be significant resulting from 1000's of man-hours spent on supplemental work	This would be included in the $5 million dollar estimate provided above.

Organization	1 - Question 13 Comments:	2 - Question 13 Comments:
	that would only serve to meet audit requirements.	
CenterPoint Energy and CPS Energy	As with our response to question 12, we believe the answer depends upon the ultimate practical interpretation of the impractical requirements.	
SRP	Estimate $30k to prepare documentation.	Estimate $15k each additional year documentation.

Response: The SDT thanks all who responded to this survey question.		

14. **System Reinforcement: One time cost, capital investment, to expand your system reinforcement program (due to lead times associated with different types of facilities, this will probably be an accumulated cost over several years). How many years do you estimate that it will take to complete this initial expanded system reinforcement program:**

Summary Consideration:

The SDT has reviewed the responses and will use the data as background information in making any further decisions with regard to this standard. No direct changes were made to any of the requirements at this time based on this information.

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
Dominion - Electric Transmission Planning	Difficult to estimate the investment required, but it will be in the millions if not hundreds of millions of dollars.	Siting new transmission in Virginia can take a minimum of 5 to 7 years if new right-of-way acquisition is required. It is difficult to provide an estimate of time, but it will be quite extensive.
NPCC	NPCC participating members have expressed compliance concerns that this standard, and in particular this question, imply NERC has the ability to "force" transmission reinforcements and construction. It should be emphasized and clarified that the standard should require transmission studies only, and per the Energy Policy Act, NERC does not have this authority as the ERO as granted by FERC in the US and NO authority allowing this in Canada. Also NPCC participating members expressed concern that a validly conducted assessment which shows that criteria are not met (in the 5 or 10 year horizon) could result in non-compliance with the Standard. If NERC believes that it can issue monetary penalties for 5 or 10 year assessments that show that performance criteria will not be met under future system conditions, there is a key question that requires explanation: What behavior is NERC attempting to incent through fining parties for conducting assessments which identify problems in a 5 to 10 year horizon? Also, NERC should further explain how it would view the relevance of a State or Provincial decision not to permit new facilities when issuing such a potential penalty such as preclusive siting issues with Generating Plants.	See above

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
TVA System Planning	Costs would include the implementation of redundant protection schemes for the P5 planning event (fault + failure of protection scheme), additional 500-kV facilities for P2.2 (single contingency - bus section outage) and P4 (fault + stuck breaker) events, and additional 161-kV facilities for the P3 (Generator +1) events. Estimated cost of $1 billion	Time duration of 10 years would be required
Progress Energy Carolinas	$100,000,000	10 years
BCTC	We do not believe that this cost is not relevant for determining the applicable standards and have not estimated it. The reinforcement costs are orders of magnitude greater that the costs of alternatives the changes in this standard propose to prohibit (e.g. use of RAS, curtailment in anticipation of the next contingency). We believe it is very unlikely that we would get approval for the projects that would be required to meet the proposed changes.	It is highly unlikely that we would be able to get funding approval for the system reinforcements required to meet the proposed changes in these standards.
Manitoba Hydro	An estimate of the cost to Manitoba Hydro is $1.0 Billion.	The licensing and construction of facilities to achieve compliance will require at least 10 years.
Los Angeles Department of Water and Power	If this question is referring to discriminatory treatment between different voltage classes that is arbitrary; the effort should be directed to either treat all the voltage classes equally or do come up with a scientific or historical basis to support the requirement. This is an engineering standard, all the criteria should have some scientific/engineering rationale that can be supported either by physics or historical data.	
National Grid	The comment period was not long enough to develop a thoughtful response to the impact that the new standards might have on the construction requirements. Therefore cost can not be reasonably speculated.	At least 5 beyond the study period. Lines requiring new Rights-of-Way may require 10.
Pacific Gas and	The capital investments would be dependent on the system	Any transmission facilities that would require a certification of

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
Electric Co.	reinforcements needed due to the added requirements. For example, if after the first contingency, redispatch to curtail firm transfers is not allowed in anticipation of the next single contingency, the system reinforcements could easily include more 500 kV lines and related facilities. The costs of such reinforcements could be a few Billion dollars.	public convenience and necessity could take more that five years for permitting, engineering and construction. Transmission Planning could take a few more years depending on the transmission reinforcements to be constructed.
Gainesville Regional Utilities	$50 Million. Again, I don't feel this is needed for smaller utilities.	7 years. Again, I don't feel this is needed for smaller utilities.
Public Service Company of New Mexico	This ultimately depends on the degree to which the local area issues addressed by footnote b of Table 1 of the existing TPL are maintained. Without the local area concepts of the existing TPL, costs could run into the hundreds of millions of dollars.	This ultimately depends on the degree to which the local area issues addressed by footnote b of Table 1 of the existing TPL are maintained. Without the local area concepts of the existing TPL, permitting requirements would result in some projects exceeding 10-years.
JEA	Could be up to $1 Billion and would depend on the physical ability to terminate at existing 500 kV substations and the ability to acquire 500 kV ROW outside of JEA's and Florida's jurisdiction.	Minimum of 7 years if DOE declares a Corridor of National Interest. Otherwise it could be longer and more costly.
PacifiCorp	$100,000,000 + Will not be able to estimate the total cost until after the studies are complete.	10 years
Puget Sound Energy, Inc.	$800,000,000 to recover Firm Transmission capacity with no adjustment following N-1.	15 years
ITC Holdings: ITC, METC, ITC Midwest	Since we have been following the NERC Planning Standards, at this point we do not expect an additional one time system reinforcement cost.	Since we have been following the NERC Planning Standards, at this point we do not expect an additional time-frame for a system reinforcement program.
Idaho Power Company	Not sure	5 years
SMUD	A field test of the revised standard would be the appropriate way to arrive at the approximate costs to support the new/modified	A field test would be the time to get an educated estimate.

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
	requirements.	
Hydro-Quebec Transenergie (HQT)	HQT and NPCC participating members have expressed compliance concerns that this standard, and in particular this question, imply NERC has the ability to "force" transmission reinforcements and construction. It should be emphasized and clarified that the standard should require transmission studies only, and per the Energy Policy Act, NERC does not have this authority as the ERO as granted by FERC in the US and NO authority allowing this in Canada. Also HQT and NPCC participating members expressed concern that a validly-conducted assessment which shows that criteria are not met (in the 5 or 10 year horizon) could result in non-compliance with the Standard. If NERC believes that it can issue monetary penalties for 5 or 10 year assessments that show that performance criteria will not be met under future system conditions, there is a key question that requires explanation: What behavior is NERC attempting to incent through fining parties for conducting assessments which identify problems in a 5 to 10 year horizon? Also, NERC should further explain how it would view the relevance of a State or Provincial decision not to permit new facilities when issuing such a potential penalty such as preclusive siting issues with Generating Plants.	
Progress Energy Florida, Inc.	Again, due to the difficulties described in the answer to Question 12a, given that the amount of analysis cannot be reasonably estimated, neither can the one-time capital cost. PEF did state in the answer to Question 11 that the cost to our 500 kV system alone would easily run in to the range of costing billions of dollars. How many billions, we are not sure, but we have sufficient experience through presently planned 500 kV projects on our system to know that the cost for such expansion is in the range of billions of dollars. Given that PEF has not been able to comprehensively assess the costs to its 230 kV and 115 kV system, it is likely that the total cost of implementing the draft TPL Standard would be many, many billions of dollars. As stated earlier, this concern is reinforced in the answer to Question 15, but	PEF does not believe the undertaking required in the present draft of the TPL Standard, questionably described here as an "initial" program, could reasonably be implemented in our lifetime. As stated in our answers to Questions 12 and 13, the planning time would run at least 10 years, or one complete long-term planning cycle. Implementation, particularly given the scope of 500 kV projects and challenges with operating the existing system while constructing such large projects, will take an additional 10 years. An estimate of 20 years, however, assumes that the industry is in place to make such projects feasible continent-wide. Just a cursory assessment of the limited resources of the Transmission Construction industry, combined with the global demand for concrete and steel, leads us to conclude that implementation of

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
	we are extremely concerned that our ratepayers will potentially be burdened with such exorbitant cost for so little benefit, and are certain that our PSC and our ratepayers will agree.	the draft Standard's requirements is not feasible short of a World War II-scale re-tooling of our entire economy. Given the significant challenges the U.S. economy is already facing, the prudency of such a colossal undertaking with minimal benefit becomes even more questionable.
Sierra Pacific Power Company / Nevada Power Company	$800 Million	10 years
Lafayette Utilities System	See response to part 1 of Question 12.	See response to part 1 of Question 12.
Arizona Public Service Co.	Hard to quantify without studying.	5 years
Ameren	Our present interpretation is that the proposed revised standard would have a minimum impact on the reinforcement of the Ameren system. The modification to remove the requirement that bus-tie circuit breakers must have the same performance requirements as non-bus-tie breakers significantly reduces our issues of non-compliance, and particularly for circuit breakers 300 kV and above.	Our present interpretation is that the proposed revised standard would have a minimum impact on the reinforcement of the Ameren system.
City of Tallahassee, FL	depending on the interpretation of the standard as currently drafted, this cost could be substantial (at least $20M) over a 5-year capital budget period (consistent with the City's current practice). It's doubtful this level of funding could be achieved/maintained given other financial pressures for local governments.	Unable to develop an answer to this question, since it depends on the ability to successfully site and permit generation and transmission facilities (which is becoming increasingly harder to complete), and the requirements of any successful siting effort may make the costs prohibitive (ie, underground transmission facilities and/or stringent controls on generating facilities).
Florida Power and Light	These costs cannot be determined without having experience with the new standard and its performance requirements. The costs of such investment could be in the 10's of billions of dollars for FPL because of the increased level of performance contemplated by the draft standard.	If we knew what was needed today, it could conceivably take up to 10 years to complete, if the projects are all feasible. Without knowing what is necessary, a fair estimate would be 20 years. This does not take into consideration that the entire industry would be competing for the same limited resources of material and manpower to complete this reinforcement. Justification would be

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
		problematic and eminent domain may not be enforceable due to the remote low probability of an N-1-1 event, and lack of a true reliability need.
Exelon Transmission Planning		Analysis has not been completed at this time to determine the extent of the additional burden, but significant expenditures, in terms of personnel, tools and transmission upgrades, are anticipated if this draft were implemented.
CenterPoint Energy and CPS Energy	We believe the proposed requirements may not impose additional capital investment for system re-enforcements for our companies. We believe we are already achieving the reliability goals embodied in the proposed requirements but in a much more efficient and cost-effective way than the overly prescriptive approach proposed in these requirements.	
SRP	Unknown costs, there are numerous raise the bar Standards, hard to determine the additional cost to SRP until the complete studies are performed and evaluated.	Unknown until the reinforcements are determined.
MidAmerican Energy Company	The additional one-time costs of system reinforcements to meet the new requirements would depend on the results of the new studies and be hard to forecast. However, if they involved just a few 345 kV substation modifications and 345 kV line additions, then MEC estimates that it would cost in the range of hundreds of millions of dollars per responsible entity.	The lead time to build new system projects would depend on the results of new studies and be hard to forecast. However, if they involved a 345 kV substation modification or a 345 kV line addition, MEC estimates that it would take 5 to 7 years to complete the new projects.
Tucson Electric Power Company	unable to determine without actual studies	10+ years5 year budget and 10 year plans have been approved. Proposed projects in the 5-10 year time frame would need revised and accelerated and new projects would be proposed following the completion of these proposed projects.
SERC Dynamics Review Subcommittee		The lead time for new line construction is at least 7 years.

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
MRO NERC Standards Review Subcommittee	The additional one-time costs of system reinforcements to meet the new requirements would depend on the results of the new studies and be hard to forecast. However, if they involved just a few 345 kV substation modifications and 345 kV line additions, then we estimate that it would cost in the range of hundreds of millions of dollars per responsible entity.	The lead time to build new system projects would depend on the results of new studies and be hard to forecast. However, if they involved a 345 kV substation modification or a 345 kV line addition, we estimate that it would take 5 to 7 years to complete the substation project and 8 to 12 years (or more) to complete the new transmission line project.
Midwest ISO	This is difficult to quantify at this time.	This is difficult to quantify at this time.
Tri-State Generatino and Transmission Association, Inc.	We do not anticipate additional investment beyond currently planned facilities.	Transmission projects generally take between 3 and 6 years to complete.
Tri-State G&T		10-Jun
Lakeland Electric	Unknown	Unknown
Southern Company Transmission	These costs cannot be determined without having experience with the new standard and its performance requirements.	
NERC and Regional Coordination	Clarity needs to be added throughout the requirements. Our interpretation of the standards as written will not result in substantial capitol investment. These standards will not have a substantial impact on improved system reliability, however; the requirements do significantly increase the manpower investment in study documentation and efforts associated with reporting study results.	
ColumbiaGrid	The new TPL Standard raises the bar of transmission system performance. This can be expected to require significant additional analysis, documentation and system reinforcements (or reduced firm transfers allowed on the system if system reinforcements are not made). We will defer to our members to provide quantification of those elements.	

Organization	1 - Question 14 Comments:	2 - Question 14 Comments:
IESO	None expected at this time.	None expected at this time.

ISO New England Inc.	See response to question 12.	See response to question 12.
Orlando Utilities Commission	$0.00 if system adjustment in preparation for the second part of N-1-1 can include firm transfer and non-consequential load adjustments when necessary. $500 Million if n-1-1 conditions must be met without firm transfer and non-consequential load -adjustments before the second event, at 230 kV and above$1 Billion if n-1-1 conditions above are met on load serving systems below 230 kV.	10 Years to meet n-1-1 without curtailment/reduction prior to the second n-1. A significant portion of the work would be in either downtown, established residential or highly sensitive environmental areas, all of which may require extensive legal proceedings to build the projects. There would also be a large amount of simultaneous work going on nationwide that would result in a shortage in construction & design personnel as well a scarcity in needed materials.
Entergy Services, Inc.	Without performing the requisite analyses, Entergy does not know definitively how much it will cost to comply with these revised standards. However, Entergy expects the cost could be up to $1 billion to become fully compliant.	15 - 20 years The time required for construction will be elongated due to the need for significant numbers of new construction projects. This will require that projects be queued by the TPs because of constraints in available materials, labor and other resources.
BPA Transmission Reliability Program	This information is not available.	This information is not available.
Response: The SDT thanks all who responded to this survey question.		

15. **(A) Do you generally support the revised standard? (B) Are you unsure whether you generally support the revised standard? or (C) Do you definitely not support the revised standard? Please check the appropriate box below. If your response is either (B) or (C), please explain your single biggest concern with the revised standard, including which specific requirement or set of requirements causes you the most concern and why.**

    A – Generally support the revised standard
    B – Unsure about supporting the revised standard
    C – Definitely do not support the revised standard

Summary Consideration: 50% of the commenters voted that they did NOT support the revised standard at this time. 35% are unsure. Some of the major issues that were raised by the industry for Question 15 include:

1. System Adjustment in event P6 - Many commenters believe that after the first N-1 in P6, curtailment of Firm Transmission Service or firm transfers should be allowed as part of System adjustment in preparation for the next N-1, citing that this is presently allowed in footnote b in existing Table 1. Otherwise, the Firm Transmission Service under normal System intact condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1. Many believe this would in effect be imposing an N-2 criterion for offering Firm Transmission Service.

SDT response: The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in Revision 3 of the Standard provides clarification.

2. Dropping local load - Many commenters opposed not being able to drop some local network Load for a single Contingency event as long as Bulk Electric System reliability was not impacted. This is presently allowed in footnote b of the existing TPL-002. However, there is no such allowance any longer for losing Non-Consequential Load for a single Contingency in the proposed draft. Many commenters suggested that orderly dropping of local network Load could limit the spread of the disturbance beyond the local area and allow BES reliability to be maintained. Some local network customer curtailments or local area Load loss has been allowed by local regulatory authorities as long as the overall reliability of the interconnected System was not impacted. This is a result of tradeoffs between providing a higher level of reliability in a local area and the cost and environmental impacts of providing that service.

SDT response: Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of the TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement. As an alternative, an entity could seek an Entity Variance for the situation described through their Regional Entity organization. In paragraph 1794 FERC clarified that "…an entity may seek a regional difference to the Reliability Standard from the ERO for case-specific circumstances". The process described by FERC as a regional difference is described in detail in the "NERC Standards Development Procedure" document under the subsection titled "Variances to NERC Reliability Standards".

3. Raising the bar for 300 kV and above - Many commenters believe that the SDT has not yet justified raising the bar on Facilities above 300 kV. Some pointed out that the higher performance requirements for Facilities >300 kV are tied to very low probability events, so the enhanced reliability is not worth the cost. Some also pointed out that disruptions on lower voltage circuits can cause real and reactive power flow fluctuations across, and eventual separation of, higher-voltage networks. Many believe that there should be no distinction in voltage classes for allowing or not allowing controlled Load shed for applicable events.

SDT response: The SAR for this standard recognized FERC orders which indicated a need to "raise the bar" for the industry. The SDT agrees and is attempting to do this in a reasonable fashion. There is significant flexibility in the Corrective Action Plans allowed for any additional performance requirements which must be met. Industry consensus, through approval of the SAR, is that revision of the existing TPL standards is appropriate.

4. Load modeling for dynamics - Many commenters believe that Load modeling is a significant open issue, such as the models for dynamic studies have yet to be developed and the data is not yet in hand. Many find this conflicting with implementation of the TPL standards due to modeling details being a gating item to completing some System studies.

SDT response: The SDT agrees and believes that industry guidance is needed to capture the appropriate dynamic behavior of Loads. In response to comments, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. Any comments received from the industry on MOD standards will be forwarded to NERC for inclusion into NERC Reliability Standards Development Projects 2010-04 Modeling Data and 2010-05 Demand Data. Requirement R2.4.1 has been modified to include the following: "An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable."

5. Sensitivity analysis - Another concern of commenters is the prescriptive nature of sensitivity scenarios, listed within Requirement R2.1.3 for steady-state and Requirement R2.4.3 for Stability, and the volume of associated study work. Some commenters feel that the Transmission Planner and Planning Coordinator can better select the most appropriate sensitivities for their System. Commenters also feel that examples of sensitivities are already inherent in the existing requirements, such that some sensitivity studies are in effect adding an additional level of Contingency (N-2 or N-3). Many commenters feel that the additional analyses proposed by the revised standard are not warranted and are already covered adequately in the existing studies and TPL standards.

SDT response: The intent of the SDT in requiring performance of sensitivity studies is to identify critical System conditions and to expand the planners' portfolio of knowledge about vulnerabilities on their System. This is also an expectation from FERC Order 693 paragraphs 1704 - 1706.

As a result of industry comments, the following changes have been made to TPL-001-1:

Consequential Load Loss: ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed, Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions.

Non-Consequential Load Loss: Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~.

Year One: The first year that a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the ~~completion of the previous annual Planning Assessment~~ current calendar year.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R2 Each Transmission Planner and Planning Coordinator shall ~~conduct and document the results of~~ prepare ~~its~~an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, document results, and shall cover steady state analyses, short circuit analyses, and Stability analyses ~~including both System and Generating Unit Stability~~.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

- ~~Variability and outages of r~~Reactive resource~~s~~ capability

R2.1.4 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.

R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable.

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.6.1 (now R2.5.1) For steady state, short circuit, or ~~System~~ Stability analysis: the study shall be five calendar years old or less.

R2.6.2 (now R2.5.2) For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

R2.7 (now R2.6) For Planning Events shown in Table 1~~ – Steady State Performance and Table 2 – Stability Performance~~, when the analysis indicates an inability of the System to meet the performance requirements in ~~the t~~Table~~s~~ 1, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall:

Under Requirement R2.6.1:

- Installation or modification of Protection Systems or Special Protection Systems
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate Steady State performance violations.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. ~~The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to c~~Contingencies~~ in Table 1 – Steady State Performance.~~ The studies shall be based on computer simulations using models utilizing data provided in Requirement R1.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.4.

R3.3.2 For all generators, studies shall consider the minimum steady state voltage limitations ~~of all generators~~ and identify how the generators are ~~treated~~ analyzed in the steady state simulation

R3.3.3 For all Transmission lines, studies shall consider relay loadability and identify how loadability is ~~treated~~ analyzed in the steady state simulation.

R3.4 Those Planning Event Contingencies in Table 1 ~~– Steady State Performance not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.

R4 For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~

R4.3.2 ~~Studies shall consider~~ Simulate generator performance under anticipated conditions including how the voltage ride through capability ~~of all generators and identify how the generators are treated~~ is analyzed~~in the simulation~~.

R4.4 ~~At a minimum, t~~Those Planning Event Contingencies in Table ~~2~~1 – ~~Stability Performance~~ that ~~would~~are expected to produce more severe System impacts shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information with an explanation of why the remaining Contingencies would produce less severe System results.

R7. Each Planning Coordinator shall coordinate the distribution of Planning Assessment results among ~~neighboring systems~~ adjacent Planning Coordinators and any functional entity who has indicated a reliability need, coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890.

Header note 'e' - For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

Extreme Event 2b (steady state) - Loss of all Transmission lines on a common ~~r~~Right-of-~~w~~Way.

Footnote 1.a.ii - For all other Planning Events: No generating unit or units totaling more than the Contingency ~~r~~Reserve of the Balancing Authority (or Reserve Sharing Group if applicable) shall be allowed to pull out of synchronism. Generators that pull out of synchronism must have out-of-step protection or some other means to trip the generator for this condition and the resulting apparent impedance swings must not pass through relay characteristics that would result in the tripping of any Transmission System elements other than the generating unit and its direct connection Facilities.

Footnote 3 - Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø fault study indicating criteria are being met shall provide sufficient evidence that a SLG condition would also meet criteria.

Footnote 5 - When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

Footnote #12 - Excludes circuits that share a common structure for 1 mile or less.

Organization	Question 15:	Question 15 Comments:
El Paso Electric Company	B — Unsure about supporting the revised standard	While this 2nd draft TPL standard has some positive changes, notably: The allowance to use RAS to trip generation for N-1 (see R3.5 Manual and automatic generation run-back/tripping is allowed as a response to a single or multiple Contingency ...) with some rather generic conditions. The allowance for Non-consequential Load Loss for loss of a transmission Facility, followed by system adjustment, followed by loss of a second transmission Facility (see P6 in draft performance Tables 1 and 2). This is the same as Category C3 in the existing TPL-003-0.On the down side, as proposed, Standard TPL-001-1:1. Will not allow curtailment of firm transfer (or firm transmission service) after the first N-1, in preparation for the next N-1 regardless of transmission voltage level. This is a major issue. Curtailment of firm transfer after the first N-1 has always been a part of system adjustment in preparation for the next N-1 as stated in foot note b of the existing TPL-002-0:"b. Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers." Not allowing this could mean reduction of firm transfer capability pre-contingency unless new circuits are built.2. The existing standard (http://www.nerc.com/files/TPL-003-0.pdf) does not distinguish between voltage classes, curtailment of firm transfer and, planned and controlled load shedding are allowed regardless of voltage class for Category C events. The proposed standard will not allow curtailment of firm transmission service, or planned and controlled load shedding for loss of Facilities with operating voltage above 300 kV involving the following in the proposed Performance Tables 1 and 2:P2-2: Bus Section fault (Category C1) P2-3: Breaker fault (Category C2) P4: SLG Fault + stuck breaker (Categories C6 - C9) P5: SLG Fault + protection system failure (Categories C6 - C9)The number of Facilities lost would depend on the bus configuration for above 300 kV. If you have a ring-bus, breaker and a half or double breaker double bus, you would lose at the most 2 Facilities. But if you have Main-Aux or single breaker double bus, you will lose all Facilities connecting to the faulted Facility.
Response: In response to your comment and those of others in the industry on allowing curtailment of Firm Transmission Service as System adjustment after		

Organization	Question 15:	Question 15 Comments:
an N-1 Contingency, the SDT has added footnotes 5 and 10 to Table 1 - Steady State & Stability Performance. **Footnote 5** - When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. **Footnote 10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
Dominion - Electric Transmission Planning	B — Unsure about supporting the revised standard	(1) Unsure about cost/effort necessary to meet requirements (2) Uncertain that compliance with the proposed requirements in this standard would significantly improve reliability (3) R2.6.2: The entire sentence is confusing as it is modified. The original sentence in the previous draft made more sense. Please check and correct accordingly. (4) R 5.3: This requirement considers voltage ride-through capability of all generators. Nowhere in this TPL standard or in the MOD standards are Generator Owners specifically required to provide such data to Transmission Planners and Planning Coordinators. Stating the requirements for generator dynamics data and dynamic load characteristics in general terms, as listed below (from the MOD Standards), are vague. (a) shall provide appropriate equipment characteristics (b) shall provide dynamics system modeling and simulation data (c) Shall develop comprehensive dynamics data requirements .... to model and analyze the dynamic behavior... (5) In Table-2 Stability Performance, several places refer to "SLG or 3-phase Faults" . Since it states "or", does this mean we can get by with studying only SLG faults? We do not think that is the intent of this phrase; thus, a clarification is warranted. (6) One of our comments on the previous draft was with respect to a second-zone fault clearing due to protection system failure for a fault beyond zone 1 coverage of primary relies. The SDT's response was (Specific 1): "The SDT agrees with your concern and is working on a solution for a future draft." The question is repeated below, as a pending "to do" item, using the revised 'Table-2 Stability Performance' as reference: Category 5 in 'Table-2 Stability Performance' refers to a protection system failure event. We interpret this as, among other things, having a fault beyond the first-zone coverage of the primary protection scheme with the carrier equipment failure (or the carrier cut-off switch left in "OFF" position by a technician - a human error) resulting in a second-zone trip of the faulted line. The second-zone trip time is generally in the range of 30-35 cycles. This may be critical from the stability aspect for the terminal end at a generating plant even though only one element will be lost. Also, the second-zone trips may need to be studied for transmission lines out of next terminal from the generator end if the next terminal is connected to the generator terminal via a short line. We think that an

<table>
<tr><th>Organization</th><th>Question 15:</th><th>Question 15 Comments:</th></tr>
<tr><td></td><td></td><td>additional single contingency Category should be added to this Table to cover the "Event" of second-zone trip scenario.</td></tr>
<tr><td colspan="3">
Response: 1. The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors and additional efforts involved and has taken them into consideration in its deliberations in the development of this draft.
2. The SAR for this standard recognized FERC orders which indicated a need to "raise the bar" for the industry. The SDT agrees and is attempting to do this in a reasonable fashion. There is significant flexibility in the Corrective Action Plans allowed for any additional performance requirements which must be met. Industry consensus, through approval of the SAR, is that revision of the existing TPL standards is appropriate.
3. The SDT has revised the language of Requirement R2.6.2 (now R2.5.2).
R2.5.2 For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:
4. The SDT understands that the Transmission Planner and the Planning Coordinator need data from the Generator Owners. However, revising the MOD standards is beyond the scope of this standard revision. Further, we note that one of the requirements of FERC Order 890 for long-term Transmission planning involves formal data exchange between stakeholders and the Transmission Planner and the Planning Coordinator. It is our understanding that these data exchange processes have been successful in providing better planning information about stakeholders such as independent Generator Owners. Also, we note that there is an ongoing standards development project, Generation Verification Project 2007-2009. You may wish to submit your comment to that SDT about the need for the Generator Owner providing this information to the Transmission Planner and the Planning Coordinator.
5. The SDT has combined the tables into a single table and clarified the "SLG or 3 phase" designations. In addition, the SDT has added footnote 3 to provide clarity.
Footnote 3 - Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø fault study indicating criteria are being met shall provide sufficient evidence that a SLG condition would also meet criteria.
6. The SDT has revised the language in the P5 category to clearly identify the required performance for an event with a Protection System failure. The current draft requires the planner to recognize the equipment that will be removed from service and the timing (including delays with back-up Protection Systems if the primary is out of service) during their Stability studies. The scenario you described is therefore covered by P5. The SDT does not see a need to have a separate event for that scenario.
</td></tr>
<tr><td>NPCC</td><td>C — Definitely do not support the revised standard</td><td>This standard as drafted does not allow exceptions for small parts of the system as long as interconnected system reliability is maintained, which is allowed in the existing TPL standards in footnotes b) and c) in Table 1. Unless such exceptions are allowed significant transfer restrictions or large reinforcements must be made. The applicable TPL footnotes are: Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall</td></tr>

Organization	Question 15:	Question 15 Comments:
		reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers. Depending on system design and expected system impacts, the controlled interruption of electric supply to customers (load shedding), the planned removal from service of certain generators, and/or the curtailment of contracted Firm (nonrecallable reserved) electric power Transfers may be necessary to maintain the overall reliability of the interconnected transmission systems. This comment form did not allow for the following items to be addressed: a. Definition of the Long-Term Planning Horizon. The planning horizon, for assessment purposes should be limited to 10 years. Such an assessment should be sufficient to identify requirements that may take an extended time to implement. b. Definition of Planning Coordinator is part of the NERC Functional Model, For consistency it should be removed from the Standard. c. Put headings on each section to identify requirements of section. Add headings to the tops of the subsequent pages in the performance tables. Headings only appear on the first page at the beginning of the Table. d. With respect to R2.2 - Delete "current" from the phrase "current System Peak Load study" and replace "study" with "assessment." e. Remove R2.2.1, the requirement to extend the assessment beyond 10 years. What does the length of the project have to do with the assessment? If it takes 15 years to build something, why does this require a review of year 15? What is the purpose of this assessment? f. R3.3.2 requires clarification - This standard needs to permit discretion regarding the single contingencies that need to be tested, similar to R 3.3.3 and R3.4. It is unnecessary to test all events. For example, contingencies may be limited to relevant disturbances that are contained within or directly impact the studied system. g. With respect to R3.2.1 - Clarify whether the intent of the standard is to address station service minimum voltage limitation, maximum leading VAR absorption capability or both at steady state. h. Remove R3.2.2 - Relay loadability is addressed in PRC-023 standard. i. With respect to R3.3.2.1 - Recommend the removal of the requirement to assess the expected duration of Consequential Load loss. It's not considered anywhere else in the standard. j. With respect to R3.3.3 - The paragraph refers to Table 1 Contingencies P3 through P7; this should be explicitly stated. Rationale for inclusion of testing should not be required; should only need to explain why certain Contingencies were not tested. This discretion should be applicable to all contingencies. k. With respect to section R5 - The concept of planned and long-term outages should apply to the general Planning Assessment, or not at all. It should not be specific to the Stability Assessment.

Organization	Question 15:	Question 15 Comments:
		l. The provisions of Section R.5.3 should have a corresponding MOD standard apply a requirement to provide information regarding all direct and indirect protective and control actions that could result in the inadvertant trip of the generator. Such a provision should include "other equipment (e.g. HVDC, SVC's, Statcoms)", and identify how these devices are treated in the simulation. m. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon.
New York Independent System Operator	C — Definitely do not support the revised standard	This standard as drafted does not allow exceptions for small parts of the system as long as interconnected system reliability is maintained, which is allowed in the existing TPL standards in footnotes b) and c) in Table 1. Unless such exceptions are allowed significant transfer restrictions or large reinforcements must be made. The applicable TPL footnotes are:? b) Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.? c) Depending on system design and expected system impacts, the controlled interruption of electric supply to customers (load shedding), the planned removal from service of certain generators, and/or the curtailment of contracted Firm (nonrecallable reserved) electric power Transfers may be necessary to maintain the overall reliability of the interconnected transmission systems. With respect to section R5 - The concept of planned and long-term outages should apply to the general Planning Assessment, or not at all. It should not be specific to the Stability Assessment. l. The provisions of Section R.5.3 should have a corresponding MOD standard apply a requirement to provide information regarding all direct and indirect protective and control actions that could result in the inadvertant trip of the generator. Such a provision should include "other equipment (e.g. HVDC, SVC's, Statcoms)", and identify how these devices are treated in the simulation. m. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizion.
Northeast Utilities	C — Definitely do not support the revised standard	Northeast Utilities has participated with ISO-NE and NPCC and supports the comments filed by those organizations.
Response: Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of the TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement. As an alternative, an entity could seek an Entity Variance for the situation described through their Regional Entity organization. In paragraph 1794 FERC clarified that "…an entity may seek a regional difference to the Reliability Standard from the ERO for case-specific circumstances". The process described by FERC as a regional difference is described in detail in the "NERC Standards Development Procedure" document under the subsection titled "Variances to NERC Reliability Standards". A. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted. FERC Order 693 requires that the planning horizon take into account the lead times for siting and permitting of new long-distance Transmission lines and other long lead time solutions. The SDT has received industry comments regarding the need to exceed a 10-year horizon to account for longer lead time projects. Establishing planning horizons that are shorter than Transmission lead times may create gaps where the identification of a reliability need to which Transmission may be the best solution occurs too late to avert the identified reliability violation. Further, Operating Procedures or alternative short-term capital projects may be needed to limit the impact of the planning event until the planned Facilities can be completed. This information needs to be included in the Assessment.		

Organization	Question 15:	Question 15 Comments:

B. Planning Coordinator has been defined in another project and as such has been deleted here.

C. The SDT also feels that the Tables need to be as clear and concise as possible. To that end, this version combined Tables 1 and 2 into one table with a revised format. The Planning Events are shown on one page so repeating the headings will not be needed.

D. The SDT believes that the existing language is appropriate. No change made.

E The SDT believes that a review of System conditions beyond the 10-year horizon is warranted under some circumstances. For example, if it takes 15 years to build a Transmission line, then the need for that line would have to be determined 15 years ahead of the in-service date. Therefore, Requirement R2.2.1 requires you to perform an Assessment on year 15 if it takes you 15 years to build a line.

F. The SDT has removed Requirement R3.3.2 and replaced it with additional language in Requirement R3.1. The SDT agrees with your interpretation that it does not require evaluation of all single Contingencies. Rather, the SDT specifically states in Requirement R3.4 that those Contingencies that are expected to produce the more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe results.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.5.

G. The SDT has not limited the purpose of this requirement to either minimum acceptable station service voltages or maximum Mvar absorption. The SDT believes that the purpose of Requirement R3.2.1 (now R3.3.2) is to determine if generators will be able to operate or trip off following the Contingency.

H. The SDT believes that relay load limits or loadability needs to be considered in the Contingency analyses. The studies should determine if Transmission line loadings could reach the relay loadability level which may add to the existing Contingency and perhaps, result in an unbounded cascading event. No change made.

I. By definition, Consequential Load Loss is allowed. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R2.~~-~~8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

J. The SDT agrees that the rationale should be for all Planning Events but not for Extreme Events.

K. The SDT agrees and has moved this concept within Requirement R1 (see Requirement R1.1.1) so that it is applicable to all planning assessments. Further, both Requirements R3 and R5 (now R4) have been revised to make reference to Requirement R1**.**

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. ~~The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to c~~C~~ontingencies in Table 1 – Steady State Performance.~~ The studies shall be

Organization	Question 15:	Question 15 Comments:
based on computer simulations using models utilizing data provided in Requirement R1. **R4** For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~ L. Requirement R5.3. has been modified (now R4.3.2) to address simulation of how generators perform under conditions being studied to address these concerns. "Other equipment" is addressed in Requirement R5.4. **R4.3.2** ~~Studies shall consider~~ Simulate generator performance under anticipated conditions including how the voltage ride through capability ~~of all generators and identify how the generators are treated~~ is analyzed~~in the simulation~~ M. While planned outages are addressed in the operating horizon, it is important that a Transmission Planner review the ability of its System to accommodate planned (maintenance) outages. Additionally, any specific known Facility outages need to be appropriately modeled for the planning horizon studied.		
TVA System Planning	C — Definitely do not support the revised standard	TVA's main concern is that no technical justification for "raising the bar" on facilities above 300-kV has yet been demonstrated such as required on P2, P4, and P5 for 300 kV and above. TVA is very concerned that "raising the bar" would be a financial burden on TVA's ratepayers. TVA would also like to provide the following additional comments to this second draft as follows: 1. In R2.4.1, load models that appropriately represent the dynamic behavior of motor loads are required. TVA believes that industry guidance is needed on how to properly model these loads. Does this requirement mandate the use of specific load models for each bus, or would an aggregate load model which represents the system as a whole be sufficient? It should be clearly stated whether the load model in R2.4.3.1 refers to system load or the dynamic load model at individual busses. 2. In R3.2.1 and R5.3, need industry guidance on how to actually determine the minimum steady state voltage limitations of generators. Is there a MOD or FAC requirement for generation owners to provide this information? 3. Which single contingency events should be included in calculations for Available Transfer Capacity? Should P2 events be included in addition to P1 events since P2 events are also defined as single contingency events in Tables? 4. Would like further clarification from the team on what does P5 exactly includes? For instance, does it include battery failures, CT failures, etc? 5. The existing TPL 002-0 allows for some local load to be dropped for a single contingency event as long as the Bulk system reliability was not impacted. However there is no such allowance any longer for losing such load for a single contingency in the proposed draft. It would be very expensive for TVA to fix all such events in several remote areas that

Organization	Question 15:	Question 15 Comments:
		would have very little impact on the overall reliability of the TVA bulk system. TVA believes that the capital spent for these fixes could be used to better strengthen the overall bulk system in much better ways. 6. Suggest rewording R2.2.1 from "To accommodate any known longer lead time projects" to "To identify any potential longer lead time projects". 7. Can operational guides be used indefinitely in R2.7.1 or does the team propose a limit on how long operational guides can be used until a capital fix is implemented? 8. In R3.3.2.1, what is the purpose for needing the expected duration of consequential load loss? There is a concern that this requirement will be very burdensome to keep track of the quantity of consequential load loss as well as expected duration. Who is requesting this info? It appears that this may be a local regulatory issue, not a reliability issue. 9. Suggest changing definition of "Planning Events" in the Definitions to say "Events that have a higher probability of occurrence and require Transmission system performance requirements to be met." 10. Should the proposed standard mention that utilities should run contingencies outside their system that could impact their own internal system? TVA believes that additional documentation be included in the new standard to address this. 11. Functional entity in 4.1.4 should be "LSE" instead of "DP" 12. In the Definitions for "Year One", suggest replacing "previous" with "most recent" to help clarify when the planning window should begin. 13. Should "peak" in R2.1.1 be replaced with "On Peak" as shown in the NERC glossary of terms? Also the requirements in this requirement are too prescriptive - should allow some flexibility to allow the TP which years to study as long as a minimum number of cases are studied. 14. Suggest replacing "Plant" in R2.6.2 with "Unit" to match terms used in Definitions. 15. In R2.7.1.1, what is meant by "project initiation date"? Is it when engineering starts, construction starts, etc? 16. Suggest rewording requirements R3.3.3 and R3.4 to be more clear - such as breaking each of these into several sentences each. Existing wording is very confusing. 17. There is a concern with R5.6.1 with the requirement to perform simulation on 20 MW generators (to be consistent with the Registration Criteria). We recommend a 75 MW generator cutoff for required simulations. Also in R5.6.2, should last word in sentence be "greater" or "lesser"? 18. In the Tables under Extreme Events, is 3.b. (loss of two TLs on different ROWs actually already covered under 1 (loss of two elements prior to system adjustments)? Also in the Tables under Extreme Events, it may be difficult for a TP to know enough about nuclear plant design to perform studies mentioned under 3.a.vi.

Organization	Question 15:	Question 15 Comments:
		19. In the notes under Extreme Events, we suggest that notes #2 and #3 be combined together since they are very similar in nature. 20. Should the P3 planning event descriptor (G+1) in the performance tables be (G+N-1) or (G-1, N-1)? The existing descriptor (G+1) tends to note that an element is being added to the system instead of being removed. 21. Should the new standard address specific voltage limit requirements that must be maintained during these planning events? Since different utilities have different voltage limits on their buses, should there be some consolidation to ensure the standard is applied equally at all utilities? 22. The note for Planning Event P1 states that “No generating unit or units shall be allowed to pull out of synchronism. A generator being disconnected from the System by Fault clearing action or by a Special Protection System is not considered pulling out of synchronism.” The standard does not allow consideration for small units with a Zone 2 fault. It is not practical to add pilot relaying on all lines from a plant with a small unit that would be stable for close-in three phase faults, and could be adequately protected when a Zone-2 fault would cause a small generator to trip off with out-of-step (OOS) protection. The table for P1 should allow small units (<75 MW) to trip using SPS or OOS protection.

Response: The SDT is attempting to raise the bar by developing a standard that appropriately supports BES reliability and has industry consensus. The majority of the SDT believes that 300 kV is an appropriate cutoff and that Transmission Systems above this level represent backbone Systems and are part of regional "grids". The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations and has provided for flexibility in Corrective Action Plans. FERC has noted in their orders that many of the concerns about raising the bar show more concern about economics than reliability (examples, Order 890, paragraph 423; Order 693, paragraph 1792, etc.).

1. The SDT agrees and believes that industry guidance is needed to capture the appropriate dynamic behavior of Loads. In response to comments, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. Any comments received from the industry on MOD standards will be forwarded to NERC for inclusion into NERC Reliability Standards Development Projects 2010-04 Modeling Data and 2010-05 Demand Data. Requirement R2.4.1 has been modified to include the following: "An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable."

2. The SDT believes that FAC-009-1, Requirements R1 and R2 require that generators provide these low voltage limitations as part of their Facility Ratings. Also, PRC-024, which is under development, will attempt to require generators to meet voltage ride-through criteria.

FERC Order 693, paragraph 1773 regarding FERC Commission directed changes to TPL-002 states "...requires all generators to ride through the same set of Category B and C contingencies as required by wind generators in Order No. 661, or to simulate those generators that cannot ride through as tripping".

The current MOD standards that address steady-state and dynamic simulation data requirements do not explicitly require the Generator Operators to provide voltage ride-through capability. These standards are set to be addressed by Project 2010-04 within NERC's Standards Development Work Plan. Based on the proposed TPL requirement, Requirement R5.3 (now R4.3.2), it is expected that the Transmission Planner would contact Generator Operators applicable to their System to obtain such data. If the data is not provided, it would be expected that a Transmission Planner state its assumption on the Vmin used for a generator

Organization	Question 15:	Question 15 Comments:

terminal voltage for assessing ride-through capability. It's likely such information could be obtained through generator manufacturers.

3. Questions related to ATC calculations are beyond the scope of this standard. Please see NERC Reliability Standard MOD 001-1, Requirement R7 & Measure M7 for additional information on ATC calculations.

4. The description of the P5 event has been clarified in this Revision of the Standard.

5. Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of the TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement.

6. The SDT believes that the existing language is appropriate. An assessment of year 15 would be needed to accommodate a Transmission line if it takes 15 years to build a line.

7. The SDT has not established a limit as to how long Operating Procedures may be used to meet System performance requirements and has left that decision for the Transmission Planner/Planning Coordinator.

8. By definition, Consequential Load Loss is allowed. To meet industry concern, as well as FERC Order 693, the SDT has added Requirement R2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

9. The definition of Extreme Events already states that these events have a lower probability of occurrence than Planning Events. The SDT did not make the change suggested by the commenter as there was no industry consensus to alter the definition.

10. The list of Contingencies is expected to cover the Transmission Planner's or Planning Coordinator's System for which they are responsible, including any tie-lines to adjacent Transmission Systems. The standard does not preclude the Transmission Planner or Planning Coordinator to expand the list of Contingencies to include some Contingencies of interest or known impact for adjacent System(s). It is expected that through peer reviews, the Transmission Planner or Planning Coordinator may initially learn of any new event within an adjacent System that impacts their own System.

11. Applicability 4.1.4 has been deleted due to the deletion of Requirements R9 – 14.

12. The SDT believes that it is not necessary to replace "previous" with "most recent" since Planning Assessments are required on an annual basis.

13. The SDT believes that the term "System peak Load" is appropriate. The SDT does not believe that Requirement R2.1.1 is too prescriptive, but is the minimum needed to gauge the timing for System reinforcements in the near-term horizon.

14. This draft of standard has been revised to remove word "plant" from Requirement R2.6.2 (now R2.5.2). Requirement R2.5.2 from the last draft of the

Organization	Question 15:	Question 15 Comments:
standard has been deleted. **R2.5.2** For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: 15. The SDT has not defined a project initiation date and will leave that definition to be determined by the Transmission Planner and/or Planning Coordinator. 16. Most of the industry did not seem to find Requirements R3.3.3 and R3.4 unclear or confusing. Therefore, the SDT has decided to not undertake any rewording. Requirements R3.3.3 and R3.4 have been relabeled as Requirements R4.4 and R4.5 respectively. 17. The requirement for study has been changed to 20 MW for a single generator or for an aggregate of generators. This language is now in Requirement R2.5.2. Requirement R5.5.2 was deleted. 18. The SDT agrees and has removed the redundancy found with Extreme Event 3.b. Having multiple nuclear units out of service simultaneously is an Extreme Event, but it has occurred. The SDT recommends that the Transmission Planner consider sensitivities with different combinations of nuclear plants being out of service, including the possibility that they are all shut down simultaneously. To reinforce the more apparent combinations, the Transmission Planner may discuss the operational requirements and the equipment and design similarities of the nuclear plants with the appropriate Resource Planner or Generator Operator to determine credible scenarios which could commonly affect the nuclear plants. 19. The SDT discussed the combining of notes 2 & 3 but felt they wanted them separate for clarity. Note 2 is focusing on interruptions of Firm Transmission Service and Non-Consequential Load and Note 3 refers to transformer outage events. 20. The SDT has deleted the parenthetical to provide clarity. 21. The SDT has addressed this issue by the Header note 'b' for Steady State Only in Table 1 - Steady State & Stability Performance, where the Planning Coordinator sets the acceptable voltage deviations. The SDT believes that adjacent Planning Coordinators can adequately address this concern. 22. The SDT believes that any unit that is tripped by out of synchronism protection is actually in an "out of synchronism" condition and this should not occur for a P1 event regardless of generator size.		
City Water, Light & Power - Springfield, Illinois	A — Generally support the revised standard	
Response: Thank you for your response.		
Omaha Public	B — Unsure	Event 1 of Category P2 in Tables 1 and 2 addresses events consisting of "Breaker(s) opening without a Fault resulting in a

Organization	Question 15:	Question 15 Comments:
Power District	about supporting the revised standard	single ended line." Category P2 is labeled as a "single contingency" category, yet it seems like an event consisting of the opening of more than one breaker would actually be a multiple contingency. Please consider whether the "(s)" should be removed after the word "breaker" in the event description so that it addresses only a single breaker opening without a Fault. Table 1 does not address multiple contingencies consisting of loss of a transmission circuit, transformer, single pole of a DC line, or shunt device, followed by System adjustments, followed by the loss of a generator. It seems like Table 1 should be modified to address this type of multiple contingency. In the description of Event 1 of Category P2 in Table 1, remove the text "Loss of one of the following:". In the description of Event 2 of Category P2 in Table 1, replace "Bus section" by "Loss of a bus section". Assuming that this does not change the intent of the drafting team, in R3.3.2.2, R3.5.1, R5.4.3.1, change "shall be operating" to "are operating". In R3.3.2.2, consider removing the phrase "and within their thermal and voltage limits", because it seems like it may be redundant given the definition of the term "Facility Rating". In the event descriptions of Categories P1, P3, and P6 of Table 2, does the term "3-phase fault" apply to DC lines? If not, consider using a separate introductory phrase with the event descriptions of Categories P1, P3, and P6 of Table 2 that involve DC lines. Also consider removing the words "Loss of" in the description of Event 4 of Category P6 in Table 2. Since a definition was developed for "Bus-tie Breaker", capitalize the terms "bus-tie" and "bus tie" wherever they appear in the standard.

Response: The SDT believes that events which can result in a single line or line section being fed radially from one end must be analyzed to ensure that Load served from the line can be reliably served from either end regardless of station configuration.

The SDT expanded the existing Table 1 description to include the requirement to study the loss of any generator followed by the loss of a transmission element. The SDT made this decision based on the fact that generator outages are more probable and in many cases have longer outage durations than transmission element outages. The SDT considered a requirement to study any outage of a transmission element followed by a generator outage but decided that this would be very burdensome for a lower probability event and therefore, decided not to add it in Table 1 of the draft standard.

P2 - The tables have been combined and the words "Loss of" have been removed.

The SDT agrees. Event 2 in P2 has been modified for clarity.

Requirement R3.3.2.2 has been deleted in favor of Header note ‘e’ in the Table. Please note that the two tables in the second draft have been reduced to one table in the third draft. Requirements R3.5.1 and R5.4.3.1 have been deleted from the Standard.

Organization	Question 15:	Question 15 Comments:
The "3-phase faults" does not apply to DC lines. The SDT has revised the Table accordingly. P6 - The tables have been combined and the words "Loss of" have been removed. The final draft will have all defined terms capitalized.		
Progress Energy Carolinas	C — Definitely do not support the revised standard	While be believe that in many ways the proposed draft standard represents an improvement of the current standard, we have a number of significant concerns that preclude our endorsement for the proposed standard as currently drafted. These include those discussed in the comments to above questions and the below additional comments.1) In both the Steady State and Stability Tables, Category P6 is the loss of a system element, following system adjustments, followed by the loss of another element. The table columns for this category say that interruption of firm transmission service is allowed. The table, however, is not clear whether the interruption of firm service is allowed as part of the system adjustment (between the outages) or whether it is only allowed after the second outage. It was stated in the NERC TPL SDT WebEx that the interruption is not allowed as part of the system adjustment. If this is the interpretation, this would be a dramatic change from the existing standard and would result in the unintended consequence of significantly reducing transfer capability of interfaces to a fraction of their currently reported capability. This would in effect be imposing an n-2 criteria for offering firm transmission service. This would not be an acceptable situation for the users, owners and operators of the bulk power system. 2) The proposed sensitivities create significant amount of additional work for the sole purpose of demonstrating compliance to this standard without any demonstratable benefit towards improving system reliability. While sensitivities should be appropriately considered in studies, this standard should not be overly prescriptive with respect to specific sensitivities or study methodologies.
Response: 1. The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in Draft 3 of the Standard provides this clarification. **Footnote #10** – <u>Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.</u> 2. The SDT agrees with the respondent that the sensitivities evaluated should be based on the individual situations and therefore, the SDT has not required specific sensitivities, but rather, required that at least one sensitivity should be evaluated for an Assessment to be complete.		
Platte River Power	A — Generally	In Tables 1 and 2, Categories P1 and P3, under the column heading "Interruption of Firm Transmission Service Allowed," change the note in the performance box to read "Yes, if transfer is dependent on the outaged Element." (Not just for a DC

Organization	Question 15:	Question 15 Comments:
Authority	support the revised standard	line Element.) This conditional statement applies to most Firm Point-To-Point Transmission Service (Firm PTP) applications where an outaged Element reduces the Transfer Capability of the PTP service if the Element cannot be restored to service after an allowable time frame (30 minutes or so) and the Transfer Capability is reduced to a Prior Outage System Conditions level. This "extended Contingency situation" could cause an interruption or curtailment to the firm service. The interruption and curtailment responses to a Contingency might be different between Firm PTP and Network Integration Transmission Service.
Response: The SDT has removed the "Yes if transfer is dependent on the outaged DC line" comments from the Table to ensure that AC and DC lines are treated equally. The draft standard does not allow interruption of Firm Transmission Service as a System response to Event P1. However, the SDT added Footnotes # 5 and 10 to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service in preparation for the next Contingency will be allowed provided there is no shedding of firm Load. **Footnote 5 -** When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
BCTC	C — Definitely do not support the revised standard	BCTC appreciates the efforts of the SDT to explore ways to improve our planning standards. We understand that some of the proposed enhancements may assist Transmission Planners with justifying the need for system reinforcements. Many areas of our system already meet the proposed improvements, for example, most (but not all) of our 500 kV system already meets the proposed standards for systems above 300 kV. We have planned our system without support from a standard. The proposed changes do not really help us in any way and have a number of undesirable consequences. Consequently, BCTC does not support a number of the proposed additions and is uncertain about supporting some of the other changes. Our concerns are summarized below under headings of System Issues and Study Issues. System Issues:1. BCTC plans, manages and operates 18,000 km of transmission in British Columbia. This includes 5700 km of 500 kV transmission lines. For the BCTC system, the proposed definitions for Consequential Load Loss and Non-consequential Load Loss, specifically that load loss due to RAS/SPS is Non-Consequential Load Loss, will provide no reliability benefits for our 500 kV transmission backbone system providing wholesale open access service and interconnecting to the rest of the western interconnection relative to what we have today. No reinforcements of this 500 kV transmission will be required as a result of these more stringent definitions. Any potential reliability benefits of any additional facilities built to comply with these definitions would be at the local service level, primarily in rural areas currently served by radial lines. The possible benefits would be small. There is a very low probability that we would get funding approval for these facilities. For most of our system including most of our backbone 500 kV and local networks in

Organization	Question 15:	Question 15 Comments:
		metropolitan and urban areas BCTC already meets the requirements for these definitions. As noted in our comments at item 3, a portion of the BCTC system above 300 kV cannot meet the proposed P1(A) > 300 kV. We require further clarification of these definitions such as allowing load shedding in local networks. Otherwise, we will not be planning a doable/plausible set of actions, but rather just generating a list of projects that will not be approved. Our resulting subsequent corrective plan will be to use load shedding RAS, which will conflict with the definitions. Order 693 does not require NERC to prohibit load shedding, only clarify the amount and duration of load shedding that is permitted (paragraphs 1795 and 1797). BCTC's concerns can be addressed by including the local network component of Footnote (b) - modify the definition of Consequential Load Loss to permit the use of RAS in local networks (including local networks interconnecting generation), by allowing Non-Consequential Load Loss for local networks in Tables 1 and 2, or by modifying the definition of BES to exempt local networks from the definition of BES. BCTC could also consider a limit on load shedding if the industry would develop one. BCTC raised these issues in our comments on the first draft. The SDT response (page 332) does not address our concerns. We also note FPL comment 7 (page 359) regarding removal of localized load reduction provided in Footnote (b). We do not believe that the SDT has addressed FPL's issue. Unless the local network component of Footnote (b) is included and we can get a clarification to address our concern with P1 (A), the proposed standard is not suitable for the BCTC system and we do not support the standard. 2. Contingency P1 needs to permit curtailment of firm service for flow through firm transmission service to prepare for the next contingency. If it does not, some flow through open access transmission customers may have less ATC available if RAS is not available to meet the new restrictions on the P6 contingency, while this ATC will be available for services sourcing or sinking within the transmission provider's system. P6 allows the use of RAS in response to the second contingency (Event). For firm service originating or sinking in our system, we can use RAS and have many RAS systems already in place. However, for flow throughs it may not be possible to implement RAS or there may be a time delay until RAS can be installed. If RAS cannot be implemented, it would be preferable to provide the firm service and curtail in preparation for the second contingency rather than deny the firm service (or require that the system be built for N-2 capability, which also may not be possible), which is what we will have to do to adhere to the new standard. The result is that flow through transactions will have to use non-firm service while non-flow-through may use exactly the same transmission for firm. Also keep in mind that while P4 and P5 are only those multiple contingencies initiated by a common mode failure, P6 is any two elements not necessarily common mode. Therefore, P6 can be more limiting than P4 or P5. For P4 and P5 contingencies the BCTC system has less dependence on RAS than does the second event of a P6. Consequently P6 will be more limiting on flow throughs than P4 and P5. Order 693 contains direction to NERC to address Footnote (b). Some commenters have taken issue with the SDT interpretation of Order 693 (e.g. FRCC item 2, page 365). Given the different interpretations and the potential for impacts on ATC, we suggest that the SDT review this issue with FERC and find out if what the SDT is proposing is what they really want. Without this change or clarification we do not support the standard. 3. Regarding Q30 in the Comments on First Draft, BCTC believes that DC and AC lines should have the same performance requirements with respect to interruption of firm transmission service. This relates to our concern above

Organization	Question 15:	Question 15 Comments:
		regarding flow through transactions. We do not understand why interruption of firm service would be an acceptable response to the loss of a single pole of a DC line (i.e. response to the contingency) but not an acceptable step to prepare for the next contingency of an AC line. We would ask that the SDT provide further explanation of its response that "many of the transfers over DC lines are automatically curtailed when the DC line is outaged" (page 220). We can do the same with AC lines for transfers sinking or sourcing within our system. Is the SDT assuming that RAS/SPS is used? We agree with the comments of FPL, FRCC, Southern Transmission and Manitoba Hydro (pages 219 and 221) and FPL (page 360, item 11). We disagree with the SDT decision to allow different performance for DC than AC lines. We do not support this element of this standard. 4. Contingency P3 should have the same performance requirement as P6. In two recent CPCN approvals for reinforcements of the BCTC backbone system, approval was granted based on generator contingencies being treated the same as transmission contingencies. We believe it highly unlikely that we would have received funding to approval to meet contingency P3. In our local service areas relying on generation for firm supply and for our bulk system, we consider dependable generator capacity on a case by case basis. We do not arbitrary assume a generator N-1 as a preexisting planning condition. We consider firm generator capability as a sensitivity case, not a planning criteria. We disagree with requiring a generator initial system condition having a more stringent performance requirement than other initial conditions. Without this change we do not support this standard. 5. BCTC is concerned that including the generator runback/tripping requirement in this standard will encourage more use of generator runback and tripping and will make it more difficult to get regulatory approval for transmission reinforcements. If retained, there needs to be a tie into reserves requirements. While we agree with permitting generator runback/tripping, at this time we are unsure about supporting this standard with this permissive requirement included. Study Issues:6. R2.5 and R5.5 on Generating Unit Stability studies are adequately addressed by FAC-001 and 002. Triggering events such as increased output or new existers need to go through our generator interconnection process and be paid for by the customer. In fact, we would not be aware of any of these triggering events unless a request comes from a customer. Without clarification of which generator studies are addressed through FAC-001 first, we do not support this standard. 7. We request that the SDT provide an explanation of why it believes it is important to maintain a distinction between system and generating unit stability studies. 8. Table 1 Steady State Performance lists 6 items above the Planning Events title. Should these be listed below the Planning Events title?

Response: 1. The SDT has added footnote 10 and clarified that for a P1 event, Transmission service could be interrupted as long as all of the Non-Consequential Load continued to be served. This draft does not allow "local network" Load to be shed for a P1 event, however, the conditions that you describe could warrant a regional difference.

Organization	Question 15:	Question 15 Comments:
Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. 2. Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for Event P1. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted interruptible Loads, in preparation for the next Contingency. 3. The SDT has removed this differentiation in the Table such that AC and DC lines will be treated equally. See footnote #10. 4. The SDT believes that the loss of a generator unit is a much more likely to occur than the loss of other major BES elements and thus the P3 event warrants more stringent performance requirements than the P6 event. The performance requirements for P3 have been clarified by addition of footnote 10 in Revision 3 of the Standard. 5. By a nearly unanimous response the Industry favors manual and automatic generation run-back and tripping as a response to a single or multiple Contingency. The SDT has eliminated the conditions in Sub-requirements R3.5.1, R3.5.2, and R3.5.3 for Contingency events as well as similar conditions in Sub-requirements R5.4.3.1, R5.4.3.2, and R5.4.3.3 for Stability events in the third draft. Accordingly, the SDT has modified Sub-requirement R3.5 for Contingency events and relocated it under Requirement R2.6.1. Likewise, the SDT has modified Sub-requirement R5.4.3 for Stability events and relocated it to become a bullet under R2.6.1. The resource adequacy issues are not directly included in this standard. In addition, with the creation of P3, the SDT has addressed the issue of the reduction of generation resources by treating the loss of one generator unit, followed by System adjustment, as the initial condition for all other single Contingencies. Therefore, the SDT does not believe that generation tripping as a corrective action needs to be tied to resource adequacy issues. Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate Steady State performance violations. Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations 6. Both Requirement R2.5 and Requirement R5.5 have been deleted since, in response to industry comments, Generating Unit Stability is no longer separately addressed in the standard. 7. Based on comments from others, the SDT has removed the requirements for separate Generating Unit Stability analysis and System Stability analysis. 8. The SDT has reformatted and combined the two Tables into a single Table for this draft to address these types of problems.		
Manitoba Hydro	C — Definitely do	Manitoba Hydro can not accept the standard due to the requirements imposed on Firm Transmission Service and on facilities >300 kV. The standard would have to allow Firm Transmission Service to be curtailed in situations where Non-

Organization	Question 15:	Question 15 Comments:
	not support the revised standard	consequential Load is not lost. The higher performance requirements for facilities >300 kV are tied to very low probability events, so the enhanced reliability is not worth the cost. TPL-001-1 Other Comment Action Plan: Schedule of Anticipated Actions needs to be revised. - Action 3 shows rev 3 out for ballot in 2Q09. TPL-00101 Purpose: Is the purpose to ?Establish Transmission System planning performance requirements? or to ?Establish planned Transmission System performance requirements? The term ?probable contingencies? is not defined or used in the standard ? use of the term may cause confusion. R7: The TP and PC are required to determine the responsibilities for performing the assessment. Are the responsibilities to be documented as part of the assessment? R8: This requirement should avoid reference to a FERC order as the order does not apply to all entities. The requirement should just require the planner to demonstrate that the assessment was distributed to potentially impacted stakeholders. The last sentence is incomplete.

Response: In response to your comment and those of others in the industry on allowing curtailment of Firm Transmission Service as a System adjustment after an N-1 Contingency, the SDT has added footnotes 5 and 10 to Table 1 - Steady State & Stability Performance.

Footnote 5 - When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

The schedule has been updated.

The SDT believes the Purpose is accurate as written because it defines planning practices and conditions to be studied. As per A.3, the purpose of Standard TPL-001-1 is to "Establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies." In this definition, the word probable is left up to the Transmission Planner/Planning Coordinator to determine so that they can set System performance requirements locally based on experience.

R7 (now R6). There is no requirement to document the responsibilities as part of the Assessment but Measure M6 in the new draft clearly states that a document must be produced as evidence that Requirement R6 has been successfully completed. This could be a standalone document or part of the Assessment at the discretion of the responsible entity.

Organization	Question 15:	Question 15 Comments:
R8 (now R7): The SDT believes the addition of the reference to the FERC Order 890 adds clarity to the expectations of the requirement without making the requirements of the Order applicable to all NERC entities. The incomplete sentence has been deleted.		
Los Angeles Department of Water and Power	C — Definitely do not support the revised standard	I do not support the standard as currently written. There are too many requirements that are discriminatory, duplicative, and arbitrary/punitive. The unintended consequence of this standard would be forcing companies and planners to plan the system to take advantage of some requirements that will result in a future system that is less robust (a single line serving multiple radial loads instead of network, for example) if not to entiely discourage any further expansion of the transmission system above 300kV (the discriminatory treatment of two classes without any rational justification).
Response: The SDT believes that the appropriate justifications have been made. The SDT changes made after the first draft were due to industry consensus. The SDT believes that these changes are justified by the various comments received from industry.		
Transmission Agency of Northern California	B — Unsure about supporting the revised standard	- We agree that the Standard as presented is clearer, but there are numerous issues that still need resolution, Measures, VSLs, Implementation Plan, etc., before we can give a full approval of this Standard. - There is no mention in the purpose of the Sta
Response: Measures, VSL's and the Implementation Plan have been addressed in the third draft of the standard.		
National Grid	B — Unsure about supporting the revised standard	Aside from the comments to the prior questions, there are several issues of concern that prevent us from supporting the present draft of the revised standard. We offer the following constructive comments in an effort to support the worthwhile effort that is being pursued so that we can reach a point of satisfaction that we could vote to support the revised standard. Our concerns are listed in a rough order of priority. a. This standard as drafted does not allow exceptions for small parts of the system as long as interconnected system reliability is maintained, which is allowed in the existing TPL standards in footnotes b) and c) in Table 1. Unless such exceptions are allowed significant transfer restrictions or large reinforcements must be made. The applicable TPL footnotes are: Existing TPL footnote b) Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers. Existing TPL footnote c) Depending on system design and expected system impacts, the controlled interruption of electric supply to customers (load shedding), the planned removal from service of certain generators, and/or the curtailment of contracted Firm (nonrecallable reserved) electric power Transfers may be necessary to maintain the overall reliability of the interconnected transmission systems.

Organization	Question 15:	Question 15 Comments:
		b. This standard does not address base conditions. Without defining base conditions the initial status of generation dispatch and transfers across the system is ill defined. Therefore the contingency analysis doesn't have a predictable basis for a consistent and repeatable study. c. The reference to Special Protection Systems is completely permissive. Although there are good applications for Special Protection Systems, their use must be constrained to have a reliable system and to promote construction of needed infrastructure. d. This standard does not provide flexibility to shed load, which restricts the ability to control post contingency response for low impact events. This may result in advancing need for upgrades in response to low impact events. This is in conflict with FERC's directive to have the Transmission Provider waiting for market response to transmission needs and having the Transmission Provider provide a role to back stop the market. e. Definition of the Long-Term Planning Horizion. The planning horizon, for assessment purposes should be limited to 10 years. Such an assessment should be sufficient to identify requirements that may take an extended time to implement. f. Definition of Planning Coordinator is part of the NERC Functional Model, Remove from Standard. g. Put headings on each section to identify requirements of section. h. With respect to R2.2 - Delete "current" from the phrase"current System Peak Load study" and replace "study" with "assessment." i. Remove R2.2.1, the requirement to extend the assessment beyond 10 years. What does the length of the project have to do with the assessment? If it takes 15 years to build something, why does this require a review of year 15? What is the purpose of this assessment? j. R3.3.2 requires clarification - This standard needs to permit discretion regarding the single contingencies that need to be tested, similar to R 3.3.3 and R3.4. It is completely unnecessary to test all events. For example, contingencies may be limited to relevant disturbances that are contained within or directly impact the studied system. k. With respect to R3.2.1 - Clarify whether the intent of the standard is to address station service minimum voltage limitation, maximum leading VAR absorption capability or both at steady state. l. Remove R3.2.2 - Relay loadability is addressed in PRC-023 standard. m. With respect to R3.3.2.1 - Recommend the removal of the requirement to assess the expected duration of Consequential Load loss. It's not considered anywhere else in the standard. n. With respect to R3.3.3 - The paragraph refers to Table 1 Contingencies P3 through P7; this should be explicitly stated. Rationale for inclusion of testing should not be required; should only need to explain why certain Contingencies were not tested. This discretion should be applicable to all contingencies.

Organization	Question 15:	Question 15 Comments:
		o. With respect to section R5 - The concept of planned and long-term outages should apply to the general Planning Assessment, or not at all. It should not be specific to the Stability Assessment. p. The provisions of Section R.5.3 should have a corresponding MOD standard apply a requirement to provide information regarding all direct and indirect protective and control actions that could result in the inadvertent trip of the generator. Such a provision should include "other equipment (e.g. HVDC, SVC's, Statcoms)", and identify how these devices are treated in the simulation. q. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon. r. What is a "current" study?

Response: A. Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement. As an alternative, an entity could seek an Entity Variance for the situation described through their Regional Entity organization. In paragraph 1794, FERC clarified that "…an entity may seek a regional difference to the Reliability Standard from the ERO for case-specific circumstances". The process described by FERC as a regional difference is described in detail in the "NERC Standards Development Procedure" document under the subsection titled "Variances to NERC Reliability Standards".

B. The SDT has modified Requirement R1 to include additional details on what should be modeled in the cases. However, the SDT intentionally provides flexibility for the Transmission Planner/Planning Coordinator to decide which "base case" to use since initial conditions for a System will vary from region to region and will need to be established on a local level, not via a national standard. The required studies and sensitivity analysis ensures that sufficient study is performed to cover an appropriate range of System conditions.

C. The SDT does not believe that it would be appropriate to attempt to specify limitations to the use of Special Protection Systems in this standard. The proposed TPL-001-1 and existing standards provide adequate guidance to the industry on application of Special Protection Systems.

D. The SDT has made clarifications regarding Firm Transmission Service and Non-Consequential Load Loss. Footnote # 10 has been added to the end of Table 1. The standard does not preclude the possibility of obtaining contractually interruptible load. It is the general opinion of the SDT that dropping of Non-Consequential Load should not be allowed for the Planning Events involving only one element as described in Table 1 of the proposed Standard, and to meet the intent of FERC Order 693. Further, this Standard is proposed to "raise the bar" to improve System reliability, which would require responses (Corrective Action Plans) to address those so-called low-impact events that may have been overlooked or ignored with the existing Standard TPL-002-0.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon,

Organization	Question 15:	Question 15 Comments:

Facility Ratings in those regions must be considered.

E. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted. FERC Order 693 requires that the planning horizon take into account the lead times for siting and permitting of new long-distance Transmission lines and other long lead time solutions. The SDT has received industry comments regarding the need to exceed a 10-year horizon to account for longer lead time projects. Establishing planning horizons that are shorter than Transmission lead times may create gaps where the identification of a reliability need to which Transmission may be the best solution occurs too late to avert the identified reliability violation. Further, Operating Procedures or alternative short-term capital projects may be needed to limit the impact of the Planning Event until the planned facilities can be completed. This information needs to be included in the Assessment.

F. The definition for Planning Coordinator was deleted because the term has already been defined and added to the NERC Glossary by another SDT.

G. The SDT also feels that the Tables need to be as clear and concise as possible. To that end, the next version will combine Tables 1 and 2 into one table with a revised format.

H. The SDT believes that the existing language is appropriate.

I. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted under some circumstances. For example, if it takes 15 years to build a Transmission line, then the need for that line would have to be determined 15 years ahead of the in-service date. Therefore, Requirement R2.2.1 requires you to perform an Assessment on year 15 if it takes you 15 years to build a line.

J. The SDT has removed Requirement R3.3.2 and replaced it with additional language in Requirement R3.1. The SDT does agree with your interpretation that it does not require evaluation of all single Contingencies. The SDT specifically states in Requirement R3.4 that those Contingencies that are expected to produce the more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe results.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.4.

K. The SDT has not limited the purpose of this requirement to either minimum acceptable station service voltages or maximum Mvar absorption. The SDT believes that the purpose of Requirement R3.2.1 (now R3.3.2) is to determine if generators could continue to operate or if they would trip off following the Contingency.

L. The SDT believes that relay load limits or loadability need to be considered in the Contingency analyses. The studies should determine if Transmission line loadings could reach the relay loadability level, which may add to the existing Contingency and perhaps, result in an unbounded cascading event.

M. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

Organization	Question 15:	Question 15 Comments:

N. The SDT has re-written Requirement R3.3 (now Requirement R3.4) to address your initial concern. Although the language and format of the proposed Standard have been revised from earlier versions, the SDT continues to believe that the Transmission Planners should evaluate the System performance for the events that are expected to produce the more severe System impacts, including both single and multi-Contingency events. The wording of new Requirement R3.4 (the old Requirement R3.3.3) now requires a listing of the Contingencies to be evaluated, the rationale for their selection and why the remaining Contingencies would be expected to produce less severe results. This will provide a complete evaluation of the potential Contingencies to be studied – those selected and those excluded.

R3.4 Those Planning Event Contingencies in Table 1 ~~– Steady State Performance not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.

O. The SDT agrees and has moved this concept within Requirement R1 (see Requirement R1.1.1) so that it is applicable to all planning Assessments. Further, both Requirement R3 and Requirement R5 (now R4) have been revised to make reference to Requirement R1.

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. ~~The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to cContingencies in Table 1 – Steady State Performance.~~ The studies shall be based on computer simulations using models utilizing data provided in Requirement R1.

R4 For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~

P. Requirement R5.3 (now R 4.3.2) has been modified to address simulation of how generators perform under conditions being studied. The current MOD standards that address steady-state and dynamic simulation data requirements do not explicitly require the Generator Operators to provide voltage ride-through capability. These standards are set to be addressed by Project 2010-04 within NERC's Standards Development Work Plan. It is expected that the Transmission Planner would contact Generator Operators applicable to their System to obtain such data. If the data is not provided, it would be expected that a Transmission Planner state its assumption on the Vmin used for a generator terminal voltage for assessing ride-through capability. It's likely such information could be obtained through generator manufacturers. The "Other equipment" is addressed in the revised Requirement R4.3.3.

Q. The SDT agrees and therefore has changed R1.1.1 to state "if specifically known."

R. The SDT believes that a current study is a study that has been completed for the latest Assessment, as opposed to a past study that may have been completed up to five years ago.

Organization	Question 15:	Question 15 Comments:
Tenaska, Inc.	A — Generally support the revised standard	A few issues that may need some thought include: Are reactive power devices a responsibility of Resource Planners in R13? On the Extreme Events description for local area, what is a load center? Does the loss of a large body of water as a cooling source result in the immediate loss of generation such that it is a contingency which affects steady state, stability, or short circuit studies?
Response: In response to industry comments, the SDT has removed Requirements R9-R14 and thus eliminated the responsibility of a Resource Planner. The SDT believes that a Load center is a location where energy is delivered by Transmission or sub-Transmission Systems to end-use customers. The loss of a large body of water as a cooling source could cause an immediate loss of generation or could only cause some generation reduction. The Transmission Planner or Planning Coordinator would need to analyze their System in order to determine the proper simulation(s).		
Pacific Gas and Electric Co.	B — Unsure about supporting the revised standard	We agree that the Standard as presented is clearer, but there are numerous issues that still need resolution, Measures, VSLs, Implementation Plan, etc., before WECC can give a full approval of this Standard. ? There is no mention in the purpose of the Standard about minimizing loss of load for more probable unplanned contingencies. Maybe there needs to be some definition around what is meant by reliability. ? We believe that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers should be allowed as part of system adjustment in preparation for the next N-1. This should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1. This will unnecessarily impede commerce. Or, to maintain the same firm power transfer under normal conditions, construction of transmission facilities will be required. Either way, this would impose a much stricter standard than exists today resulting in very costly unnecessary system improvements and invalidate terms of many transmission service contracts that allow for implementation of pro-rate curtailments of firm transmission rights during forced and planned outage conditions.? We disagree with the application of the proposed definitions of Consequential Load Loss and Non-Consequential Load Loss in conjunction with “raising the bar”. Local Network load should be included in Consequential Load and the loss should be allowed for single contingencies. The TPL standard is to maintain reliability of the BES. Under certain conditions orderly dropping of local network load could limit the spread of the disturbance beyond the local area and allow BES reliability to be maintained. This would minimize the total amount of load loss and allow for quicker load restoration. The proposed definitions for Consequential Load Loss and Non-consequential Load Loss will provide no reliability benefits for high voltage (>300 kV) transmission backbone system providing wholesale open access service and interconnecting to the rest of the western interconnection. Any potential reliability benefits of any additional facilities built to comply with these definitions would be at the local service level. As mention in comments to Q3 above, some local network customer

Organization	Question 15:	Question 15 Comments:
		curtailments or local area load loss has been allowed by local regulatory authorities as long as the overall reliability of the interconnected system was not impacted. This is a result of tradeoffs between providing a higher level of reliability in a local area and the cost and environmental impacts of providing that service. Such tradeoffs are subject to local regulatory authority or contract negotiated between the transmission provider and its transmission customers. Regarding the terms interruption of firm transmission service?, there needs be clarification on what Interruption means. Since it is referring to firm transmission service, we would interpret this to mean curtailment needed after a particular contingency and adjustments. There also needs to be clarification on what Firm Transmission Service? means. Two points, 1) the NERC definition states ?highest quality service offered to customers under a filed rate schedule that anticipates no planned interruption.? The Standard implies anticipation of ?unplanned? interruption for certain contingencies. 2) Is this referring to a transmission product as defined in FERC Order 890, or firm transfers modeled for the conditions being studied? One way to interpret the intent is the firm transfers being modeled for the conditions in the powerflow to meet demand that would result in load not being served if that firm transfer were curtailed. If there is other generation in the system that could increase to meet the load if the transfer being modeled is interrupted, then interruption of firm transmission service should also be allowed for P1 through P5 contingencies in the table. In addition, we believe that DC and AC lines should have the same performance requirements with respect to interruption of firm transmission service. We do not understand why interruption of firm service would be an acceptable response to the loss of a single pole of a DC line (i.e. response to the contingency) but not an acceptable response to prepare for the next contingency of an AC line. The transfers over both AC and DC lines can automatically be curtailed when the line is outaged.
Public Service Company of New Mexico	C — Definitely do not support the revised standard	We agree that the Standard as presented is clearer, but there are numerous issues that still need resolution, Measures, VSLs, Implementation Plan, etc., before WECC can give a full approval of this Standard. ? There is no mention in the purpose of the Standard about minimizing loss of load for more probable unplanned contingencies. Maybe there needs to be some definition around what is meant by reliability. ? We believe that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers should be allowed as part of system adjustment in preparation for the next N-1. This should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1. This will unnecessarily impede commerce. Or, to maintain the same firm power transfer under normal conditions, construction of transmission facilities will be required. Either way, this would impose a much stricter standard than exists today resulting in very costly unnecessary system improvements and invalidate terms of many transmission service contracts that allow for implementation of pro-rate curtailments of firm transmission rights during forced and planned outage conditions.? We disagree with the application of the proposed definitions of Consequential Load Loss and Non-Consequential Load Loss in conjunction with ?raising the bar?. Local Network load should be included in Consequential Load and the loss

Organization	Question 15:	Question 15 Comments:
		should be allowed for single contingencies. The TPL standard is to maintain reliability of the BES. Under certain conditions orderly dropping of local network load could limit the spread of the disturbance beyond the local area and allow BES reliability to be maintained. This would minimize the total amount of load loss and allow for quicker load restoration. The proposed definitions for Consequential Load Loss and Non-consequential Load Loss will provide no reliability benefits for high voltage (>300 kV) transmission backbone system providing wholesale open access service and interconnecting to the rest of the western interconnection. Any potential reliability benefits of any additional facilities built to comply with these definitions would be at the local service level. ? As mention in comments to Q3 above, some local network customer curtailments or local area load loss has been allowed by local regulatory authorities as long as the overall reliability of the interconnected system was not impacted. This is a result of tradeoffs between providing a higher level of reliability in a local area and the cost and environmental impacts of providing that service. Such tradeoffs are subject to local regulatory authority or contract negotiated between the transmission provider and its transmission customers. Regarding the terms ?interruption of firm transmission service?, there needs be clarification on what Interruption means. Since it is referring to firm transmission service, we would interpret this to mean curtailment needed after a particular contingency and adjustments. There also needs to be clarification on what “Firm Transmission Service” means. Two points, 1) the NERC definition states ?highest quality service offered to customers under a filed rate schedule that anticipates no planned interruption.? The Standard implies anticipation of “unplanned” interruption for certain contingencies. 2) Is this referring to a transmission product as defined in FERC Order 890, or firm transfers modeled for the conditions being studied? One way to interpret the intent is the firm transfers being modeled for the conditions in the powerflow to meet demand that would result in load not being served if that firm transfer were curtailed. If there is other generation in the system that could increase to meet the load if the transfer being modeled is interrupted, then interruption of firm transmission service should also be allowed for P1 through P5 contingencies in the table. In addition, we believe that DC and AC lines should have the same performance requirements with respect to interruption of firm transmission service. We do not understand why interruption of firm service would be an acceptable response to the loss of a single pole of a DC line (i.e. response to the contingency) but not an acceptable response to prepare for the next contingency of an AC line. The transfers over both AC and DC lines can automatically be curtailed when the line is outaged.
Puget Sound Energy, Inc.	C — Definitely do not support the revised standard	We agree that the Standard as presented is clearer, but there are numerous issues that still need resolution, Measures, VSLs, Implementation Plan, etc., before PSE can give a full approval of this Standard. There is no mention in the purpose of the Standard about minimizing loss of load for more probable unplanned contingencies. Maybe there needs to be some definition around what is meant by reliability. We believe that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers should be allowed as part of system adjustment in preparation for the next N-1. This should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting

Organization	Question 15:	Question 15 Comments:
		performance requirements after N-1-1. This will unnecessarily impede commerce. Or, to maintain the same firm power transfer under normal conditions, construction of transmission facilities will be required. Either way, this would impose a much stricter standard than exists today resulting in very costly unnecessary system improvements and invalidate terms of many transmission service contracts that allow for implementation of pro-rate curtailments of firm transmission rights during forced and planned outage conditions. We disagree with the application of the proposed definitions of Consequential Load Loss and Non-Consequential Load Loss in conjunction with "raising the bar". Local Network load should be included in Consequential Load and the loss should be allowed for single contingencies. The TPL standard is to maintain reliability of the BES. Under certain conditions orderly dropping of local network load could limit the spread of the disturbance beyond the local area and allow BES reliability to be maintained. This would minimize the total amount of load loss and allow for quicker load restoration. The proposed definitions for Consequential Load Loss and Non-consequential Load Loss will provide no reliability benefits for high voltage (>300 kV) transmission backbone system providing wholesale open access service and interconnecting to the rest of the western interconnection. We disagree with the application of the proposed definitions of Consequential Load Loss and Non-Consequential Load Loss in conjunction with "raising the bar". Local Network load should be included in Consequential Load and the loss should be allowed for single contingencies. The TPL standard is to maintain reliability of the BES. Under certain conditions orderly dropping of local network load could limit the spread of the disturbance beyond the local area and allow BES reliability to be maintained. This would minimize the total amount of load loss and allow for quicker load restoration. The proposed definitions for Consequential Load Loss and Non-consequential Load Loss will provide no reliability benefits for high voltage (>300 kV) transmission backbone system providing wholesale open access service and interconnecting to the rest of the western interconnection. Any potential reliability benefits of any additional facilities built to comply with these definitions would be at the local service level. As mention in comments to Q3 above, some local network customer curtailments or local area load loss has been allowed by local regulatory authorities as long as the overall reliability of the interconnected system was not impacted. This is a

Organization	Question 15:	Question 15 Comments:
		result of tradeoffs between providing a higher level of reliability in a local area and the cost and environmental impacts of providing that service. Such tradeoffs are subject to local regulatory authority or contract negotiated between the transmission provider and its transmission customers. Regarding the terms “interruption of firm transmission service”, there needs be clarification on what Interruption means. Since it is referring to firm transmission service, we would interpret this to mean curtailment needed after a particular contingency and adjustments. There also needs to be clarification on what “Firm Transmission Service” means. Two points, 1) the NERC definition states ?highest quality service offered to customers under a filed rate schedule that anticipates no planned interruption.? The Standard implies anticipation of “unplanned” interruption for certain contingencies. 2) Is this referring to a transmission product as defined in FERC Order 890, or firm transfers modeled for the conditions being studied? One way to interpret the intent is the firm transfers being modeled for the conditions in the powerflow to meet demand that would result in load not being served if that firm transfer were curtailed. If there is other generation in the system that could increase to meet the load if the transfer being modeled is interrupted, then interruption of firm transmission service should also be allowed for P1 through P5 contingencies in the table. In addition, we believe that DC and AC lines should have the same performance requirements with respect to interruption of firm transmission service. We do not understand why interruption of firm service would be an acceptable response to the loss of a single pole of a DC line (i.e. response to the contingency) but not an acceptable response to prepare for the next contingency of an AC line. The transfers over both AC and DC lines can automatically be curtailed when the line is outaged.
Alberta Electric System Operator	C — Definitely do not support the revised standard	We agree that the Standard as presented is clearer, but there are numerous identified issues that still need resolution, in addition to the Measures, VSLs, Implementation Plan, etc., before AESO could give a full approval of this Standard. – There is no mention in the purpose of the Standard about minimizing loss of load for more probable unplanned contingencies. Maybe there needs to be some definition around what is meant by reliability. – We believe that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers should be allowed as part of system adjustment in preparation for the next N-1. This should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1. This will unnecessarily impede commerce. Or, to maintain the same firm power transfer under normal conditions, construction of transmission facilities will be required. Either way, this would impose a much stricter standard than exists today resulting in very costly unnecessary system improvements and invalidate terms of many transmission service contracts that allow for implementation of pro-rate curtailments of firm transmission rights during forced and planned outage conditions.- We disagree with the application of the proposed definitions of Consequential Load Loss and Non-Consequential Load Loss in conjunction with ?raising the bar? for loss of Facilities with operating voltages 300 kV or higher (P2, P4, and P5 in the Performance Tables). We believe there should be no distinction between the voltage classes.-

Organization	Question 15:	Question 15 Comments:
		Regarding the terms ?interruption of firm transmission service?, there needs be clarification on what Interruption means. Since it is referring to firm transmission service, we would interpret this to mean curtailment needed after a particular contingency and adjustments. There also needs to be clarification on what ?Firm Transmission Service? means. Two points, 1) the NERC definition states ?highest quality service offered to customers under a filed rate schedule that anticipates no planned interruption.? The Standard implies anticipation of ?unplanned? interruption for certain contingencies. 2) Is this referring to a transmission product, or firm transfers modeled for the conditions being studied? One way to interpret the intent is the firm transfers being modeled for the conditions in the powerflow to meet demand that would result in load not being served if that firm transfer were curtailed. We disagree with the application of the proposed definitions of Consequential Load Loss and Non-Consequential Load Loss in conjunction with ?raising the bar?. Local Network load should be included in Consequential Load and the loss should be allowed for single contingencies. The TPL standard is to maintain reliability of the BES. Under certain conditions orderly dropping of local network load could limit the spread of the disturbance beyond the local area and allow BES reliability to be maintained. This would minimize the total amount of load loss and allow for quicker load restoration. The proposed definitions for Consequential Load Loss and Non-consequential Load Loss will provide no reliability benefits for

Organization	Question 15:	Question 15 Comments:
		high voltage (>300 kV) transmission backbone system providing wholesale open access service and interconnecting to the rest of the western interconnection. Any potential reliability benefits of any additional facilities built to comply with these definitions would be at the local service level.? As mention in comments to Q3 above, some local network customer curtailments or local area load loss has been allowed by local regulatory authorities as long as the overall reliability of the interconnected system was not impacted. This is a result of tradeoffs between providing a higher level of reliability in a local area and the cost and environmental impacts of providing that service. Such tradeoffs are subject to local regulatory authority or contract negotiated between the transmission provider and its transmission customers. Regarding the terms ?interruption of firm transmission service?, there needs be clarification on what Interruption means. Since it is referring to firm transmission service, we would interpret this to mean curtailment needed after a particular contingency and adjustments. There also needs to be clarification on what “Firm Transmission Service” means. Two points, 1) the NERC definition states ?highest quality service offered to customers under a filed rate schedule that anticipates no planned interruption.? The Standard implies anticipation of ?unplanned? interruption for certain contingencies. 2) Is this referring to a transmission product as defined in FERC Order 890, or firm transfers modeled for the conditions being studied? One way Comment Form for 2nd Draft of Standard TPL-001-1Assess Transmission Future Needs (Project 2006-02) Page 12 of 12to interpret the intent is the firm transfers being modeled for the conditions in the powerflow to meet demand that would result in load not being served if that firm transfer were curtailed. If there is other generation in the system that could increase to meet the load if the transfer being modeled is interrupted, then interruption of firm transmission service should also be allowed for P1 through P5 contingencies in the table. In addition, we believe that DC and AC lines should have the same performance requirements with respect to interruption of firm transmission service. We do not understand why interruption of firm service would be an acceptable response to the loss of a single pole of a DC line (i.e. response to the contingency) but not an acceptable response to prepare for the next contingency of an AC line. The transfers over both AC and DC lines can automatically be curtailed when the line is outaged.

Response: Measures, VSL's, and the Implementation Plan will be addressed in the next draft of the standard.

The NERC standards are based on deterministic principles. Probability is considered in a high level perspective as a means of rationalizing the inclusion of various deterministic events; however it is difficult to discuss probability in this context without creating misunderstandings. The SDT recommends that you review the NERC definition of Adequate Level of Reliability (ALR), which is the reliability goal for all NERC standards. In response to your comment and those of others in the industry, the SDT has proposed differentiating between loss of firm Load and loss of Firm Transmission Service. This differentiation is provided in footnotes 5 and 10 to Table 1 - Steady State & Stability Performance. In the event that loss of Firm Transmission Service is inadequate, the SDT believes that there are alternatives to loss of Load or construction. For example, companies may contract with interruptible Load and shed customers voluntarily.

Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not

Organization	Question 15:	Question 15 Comments:
permitted for single Contingency events. This position was vetted in draft 1 of TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement. Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for Event P1. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted interruptible Loads, in preparation for the next Contingency. "Firm Transmission Service" is a NERC defined term and is also addressed by FERC in OATT. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. The SDT has removed this differentiation in the Table such that AC and DC lines will be treated equally.		
Gainesville Regional Utilities	C — Definitely do not support the revised standard	First, a starting point for the study process (base case) needs to be better defined even if the intent was to allow the TP's & PC's to make the decision. The standard should describe the rules to properly conduct a base case study within each region. This should support any following analysis studies and their finding since you will be starting from the same set of system elements operating at a base condition. Secondly, this standard should focus on what is best for the customer considering 1) the probability of the contingency events, 2) the potential expense to the customer for practically NO improvement in BES reliability, and 3)the extraordinary added burden on the smaller utilities to run additional, no added value studies with documentation to meet an exhausted detailed audit with the potential for penalties probably not proportioned to the utilities revenue stream.
Response: The SDT has modified Requirement R1 to include additional details on what should be modeled in the cases. However, the SDT intentionally provides flexibility for the Transmission Planner/Planning Coordinator to decide which "base case" to use since initial conditions for a system will vary from region to region and will need to be established on a local level, not via a national standard. The required studies and sensitivity analysis ensures that sufficient study is performed to cover an appropriate range of System conditions. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations. The SDT has retained the basis of the previous standard and raised the bar in some respects. While the performance requirements must be met, they do not necessarily mandate a solution. Considerable flexibility in Corrective Action Plans allows for economic considerations. The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors (including ROW) involved here and is		

Organization	Question 15:	Question 15 Comments:
taking them into consideration in its deliberations.		
Lakeland electric	B — Unsure about supporting the revised standard	Suggested changes listed below to more directly address what I think is the intent of the item: Planning Events: Events that require Transmission system performance requirements to be met. Comment: I think that this suggested revision better defines a Planning Event and how they may be used in a study or assessment. Revision to: Planning Events Planning Events: Simulated events that are modeled to test the Transmission system's ability to meet performance requirements. R2.6.2. For steady state, short circuit, Generating Plant Stability, or System Stability analysis: the study shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Comment: the requirement as stated leaves one guessing about the usability of a study that may have included the changes that occurred in the intervening period. Changes that were studied but not implemented could also invalidate a study they were included in. Revision to R2.6.2R2.6.2. For steady state, short circuit, Generating Plant Stability, or System Stability analysis: the study shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that were not included in the original study but have occurred in the intervening period and would impact the study area results.
Response: The SDT did not incorporate the commenter's suggested change and the Planning Event definition remains the same as in Draft 2. The SDT believes the stated definition more correctly indicates the intent that for Planning Events the performance requirements must be met, not simply that simulations need to be completed to indicate if the performance requirements are met or not. The SDT does not agree with your comment and believes that the cancellation of a planned Facility that was included in prior models would be a material change to the network model and therefore would not allow the past study to support the Planning Assessment. The key phrase within the requirement is "the study", therefore, the intent is model simulation changes and not limited only to real physical System changes. Therefore, the SDT believes the instance raised by the commenter is adequately covered.		
JEA	C — Definitely do not support the revised standard	The inability to curtail Firm Transmission Service under P6 assessments in preparation for the next N-1 event. Also, under P1 and lower probability contingency events, JEA recommends a standard requirement that allows for the loss of Non-Consequential load during short term periods (suggest allowing up to 3 year minimum) where the system load growth has caused post-contingency remedial action plans to not be completely affective in bringing the Facility(ies) within normal operating limits. As a specific theoretical example, lets say a 10 year assessment shows load growth causing this situation in year 5, but in year 7 generators are added to the area of concern and the issue is resolved, but in year 6, Non-consequential load is required to be shed, do we still need to propose a capital improvement project?
Response: The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is		

Organization	Question 15:	Question 15 Comments:
necessary. Footnote 10 in the Revision 3 of the Standard provides clarification. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. The proposed standard does not require capital improvements, but it does require the performance metrics to be achieved. Certainly there will be circumstances where the addition of Transmission or generation facilities may be the only practical solution. For the specific example that you described, if there were no acceptable Operating Procedures to bridge the time period before the generator comes on line, entering into interruptible Load contracts would be another option. The standard does not preclude such actions.		
PacifiCorp	A — Generally support the revised standard	We generally agree with the Standard as presented so far, but there are numerous issues that still need resolution, Measures, VSLs, Implementation Plan, etc., before WECC can give a full approval of this Standard. We believe that with the loss of the first N-1 in P6, curtailment of firm transmission service or firm transfers should be allowed as part of system adjustment in preparation for the next N-1. This should be added to R3.3.2.2. Otherwise, the power transfer under normal condition (before the first N-1) will have to be significantly curtailed in anticipation for meeting performance requirements after N-1-1. This will unnecessarily impede commerce.
Response: Measures, VSL's, and the Implementation Plan will be addressed in the next draft of the standard. The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in the Revision 3 of the Standard provides clarification. Requirement R3.3.2.2 has been deleted in favor of Header note 'e' in the Table. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
ITC Holdings: ITC, METC, ITC Midwest	B — Unsure about supporting the revised standard	ITC and ITC Midwest biggest concerns are some missed opportunities to "raise the bar". We believe the draft standard is a significant improvement over existing standards which are largely fill-in-the-blank. However, we have some concerns regarding some of the language wherein CAPs are not required, even though a performance requirement has been violated. For example, providing for a bare minimum sensitivity study and not requiring a CAP based on a performance violation may increase operational awareness but does not ?raise the bar? or improve transmission performance. Allowing for non-consequential load loss following a shutdown and contingency might be an acceptable real time operating

Organization	Question 15:	Question 15 Comments:
		procedure but is not a significant advancement on a transmission planning basis. Frequently, operating procedures like this should lead to a planning solution, particularly above 300kV
Response: The SDT translated the existing TPL standards, added clarity, and "raised the bar" in areas where the SDT believes are merited. Even though the existing TPL standards do not address sensitivities, the SDT has added a requirement to complete at least one additional sensitivity. The SDT believes that it is important and valuable for the Transmission Planner and Planning Coordinator to run significant sensitivities and share the results with their neighbors. The SDT did not limit when Operating Procedures, other than Non-Consequential Load loss, could be utilized. The SDT believes that it is important for the Transmission Planner and Planning Coordinator to determine when an Operating Procedure can be utilized and when new Facilities need to be constructed. A Corrective Action Plan is required for all performance violations of all Planning Events in Table 1, except, as you have noted for sensitivity study performance violations. The SDT concurred with the FERC orders that sensitivity study results do not necessarily result in a Corrective Action Plan. From paragraph 1704 of Order 693: "The Commission notes that it is not the purpose of sensitivity studies to identify remedial actions, but, as stated in the NOPR, if different scenarios that lead to criteria violations are probable they require mitigation plans………. In any case, we are not requiring the construction of additional facilities." While the standard does not "require" a Corrective Action Plan, it does not preclude a Corrective Action Plan, particularly if it meets FERC requirements for a "mitigation" plan if the Planning Events are "probable". The majority of the SDT, based on industry comments, did not feel that Non-Consequential Load loss should be precluded from N-1-1 events. A Corrective Action Plan is not required if Non-Consequential Load loss is allowed under local criteria but the standard does not prevent local criteria from prohibiting Non-Consequential Load loss for N-1-1 events.		
Hydro-Quebec Transenergie (HQT)	C — Definitely do not support the revised standard	This standard as drafted does not allow exceptions for small parts of the system as long as interconnected system reliability is maintained, which is allowed in the existing TPL standards in footnotes b) and c) in Table 1. Unless such exceptions are allowed significant transfer restrictions or large reinforcements must be made. The applicable TPL footnotes are:? Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.? Depending on system design and expected system impacts, the controlled interruption of electric supply to customers (load shedding), the planned removal from service of certain generators, and/or the curtailment of contracted Firm (nonrecallable reserved) electric power Transfers may be necessary to maintain the overall reliability of the interconnected transmission systems.? This comment form did not allow for the following items to be addressed:? a. Definition of the Long-Term Planning Horizon. The planning horizon, for assessment purposes should be limited to 10 years. Such an assessment should be sufficient to identify requirements that may take an extended time to implement.? b. Definition of Planning Coordinator is part of the NERC Functional Model, For consistency it should be removed from the Standard.? c. We propose that the Standard be subdivided by subjects into 4 different Standards : ? TPL-001-1: Modeling and System Assessment (R1, R2, R9 to R14)? TPL-002-1: Short circuit and Steady State Performance (R3, R4)? TPL-003-1: Stability Performance (R5)? TPL-004-1: Coordination (R6, R7, R8)? If the previous proposition is not retained, at least the Standard

Organization	Question 15:	Question 15 Comments:
		Requirements should be organized by topics (Modeling, Assessment, Coordination, etc.) and headings put on each section to identify requirements of section. Add headings to the tops of the subsequent pages in the performance tables. Headings only appear on the first page at the beginning of the Table.? d. With respect to R2.2 - Delete "current" from the phrase" current System Peak Load study" and replace "study" with "assessment."? e. Remove R2.2.1, the requirement to extend the assessment beyond 10 years. What does the length of the project have to do with the assessment? If it takes 15 years to build something, why does this require a review of year 15? What is the purpose of this assessment?? f. R3.3.2 requires clarification - This standard needs to permit discretion regarding the single contingencies that need to be tested, similar to R 3.3.3 and R3.4. It is unnecessary to test all events. For example, contingencies may be limited to relevant disturbances that are contained within or directly impact the studied system.? g. With respect to R3.2.1 - Clarify whether the intent of the standard is to address station service minimum voltage limitation, maximum leading VAR absorption capability or both at steady state.? h. Remove R3.2.2 - Relay loadability is addressed in PRC-023 standard.? i. With respect to R3.3.2.1 - Recommend the removal of the requirement to assess the expected duration of Consequential Load loss. It's not considered anywhere else in the standard.? j. With respect to R3.3.3 - The paragraph refers to Table 1 Contingencies P3 through P7; this should be explicitly stated. Rationale for inclusion of testing should not be required; should only need to explain why certain Contingencies were not tested. This discretion should be applicable to all contingencies.? k. With respect to section R5 - The concept of planned and long-term outages should apply to the general Planning Assessment, or not at all. It should not be specific to the Stability Assessment. ? l. The provisions of Section R.5.3 should have a corresponding MOD standard apply a requirement to provide information regarding all direct and indirect protective and control actions that could result in the inadvertent trip of the generator. Such a provision should include "other equipment (e.g. HVDC, SVC's, Statcoms)", and identify how these devices are treated in the simulation.? m. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon. ? n. In both Table 1 and Table 2, note 3, "variable frequency transformers" should be removed from the last sentence. A new sentence should be added for reference voltage as it applies to "variable frequency transformers" and "back-to-back" facilities.

Organization	Question 15:	Question 15 Comments:

Response: Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of the TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement.

A. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted. FERC Order 693 requires that the planning horizon take into account the lead times for siting and permitting of new long-distance Transmission lines and other long lead time solutions. The SDT has received industry comments regarding the need to exceed a 10-year horizon to account for longer lead time projects. Establishing planning horizons that are shorter than Transmission lead times may create gaps where the identification of a reliability need to which Transmission may be the best solution occurs too late to avert the identified reliability violation. Further, Operating Procedures or alternative short-term capital projects may be needed to limit the impact of the planning event until the planned Facilities can be completed. This information needs to be included in the Assessment.

B. The definition for Planning Coordinator was deleted because the term has already been defined and added to the NERC Glossary by another SDT.

C. The SDT agrees with FERC Order 693 in aggregating all of the planning requirements into a single standard. The SDT also feels that the Tables need to be as clear and concise as possible. To that end, this version combined Tables 1 and 2 into one table with a revised format. The Planning Events are shown on one page so repeating the headings will not be needed.

D. The SDT believes that the existing language is appropriate. No change made.

E The SDT believes that a review of System conditions beyond the 10-year horizon is warranted under some circumstances. For example, if it takes 15 years to build a Transmission line, then the need for that line would have to be determined 15 years ahead of the in-service date. Therefore, Requirement R2.2.1 requires you to perform an Assessment on year 15 if it takes you 15 years to build a line.

F. The SDT has removed Requirement R3.3.2 and replaced it with additional language in Requirement R3.1. The SDT agrees with your interpretation that it does not require evaluation of all single Contingencies. Rather, the SDT specifically states in Requirement R3.4 that those Contingencies that are expected to produce the more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe results.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.5.

G. The SDT has not limited the purpose of this requirement to either minimum acceptable station service voltages or maximum Mvar absorption. The SDT believes that the purpose of Requirement R3.2.1 (now R3.3.2) is to determine if generators will be able to operate or trip off following the Contingency.

H. The SDT believes that relay load limits or loadability needs to be considered in the Contingency analyses. The studies should determine if Transmission line loadings could reach the relay loadability level which may add to the existing Contingency and perhaps, result in an unbounded cascading event. No change made.

Organization	Question 15:	Question 15 Comments:
I. By definition, Consequential Load Loss is allowed. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R2.~~-~~8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8. **R2.8** The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1. J. The SDT agrees that the rationale should be for all Planning Events but not for Extreme Events. K. The SDT agrees and has moved this concept within Requirement R1 (see Requirement R1.1.1) so that it is applicable to all planning assessments. Further, both Requirements R3 and R5 (now R4) have been revised to make reference to Requirement R1**.** **R1.1.1** Planned outages of generation and Transmission Facilities, if specifically known. **R3**. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. ~~The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to c~~Contingencies ~~in Table 1 – Steady State Performance.~~ The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. **R4** For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~ L. Requirement R5.3 (now R4.3.2) has been modified to address simulation of how generators perform under conditions being studied. "Other equipment" is addressed in Requirement R5.4. **R4.3.2** ~~Studies shall consider~~ Simulate generator performance under anticipated conditions including how the voltage ride through capability ~~of all generators and identify how the generators are treated~~ is analyzed~~in the simulation~~ M. While planned outages are addressed in the operating horizon, it is important that a Transmission Planner review the ability of its System to accommodate planned (maintenance) outages. Additionally, any specific known Facility outages need to be appropriately modeled for the planning horizon studied. N. Tables 1 and 2 have been combined into one table for the next posting. The SDT believes that it has adequately addressed "variable frequency transformers" as well as "back-to-back" facilities by including it in the same note as other transformers (Note #3).		
Progress Energy Florida, Inc.	C — Definitely do not support the revised	PEF considers the draft TPL Standard in its present state to be infeasible, unnecessary, burdensome and inferior to the existing Standards. The basic approach to equate reliability of the BES to whether or not Firm Transmission Service and/or Non-Consequential Load Loss can be sustained is an erroneous approach, is not justifiable, infringes upon

Organization	Question 15:	Question 15 Comments:
	standard	regulation already in place as part of dealings with the Florida Public Service Commission (PSC), and infringes upon requirements in the OATT. Given the numerous concerns PEF has with the revised draft Standard, expounding on those concerns requires extensive documentation. We therefore cannot reduce our concerns down to a single issue, nor can we single out a single requirement or set of requirements as the top concern, other than to say that the entire Standard development process either needs to be discontinued or the SDT should provide detail as to how much consideration would be given to transmission systems with historically excellent reliability via a variance process. The following is a list of PEF's primary concerns with the revised draft Standard and explanation as to why the Standard development process should be discontinued: 1. PEF has planned to, and demonstrated compliance with, the existing TPL Standards for several years now. PEF is intimately familiar with the existing Standards, and has done an excellent job in planning the PEF system, in conjunction with the other Transmission Owner members of FRCC, non-FRCC adjacent Transmission Owners, and all requestors of Transmission or Generator Interconnection Service using the existing TPL Standards. PEF thus believes that history has shown, particularly within the realm of PEF's Transmission Planning boundaries, that the existing four TPL Standards are not inadequate or inferior in any way. Statements in recent months alluding to the existing Standards? inferiority, confusing language or language subject to opposing interpretations, do not hold up when applied to the PEF and FRCC systems. PEF thus does not believe the Standards require modification. 2. PEF, through its aforementioned participation with FRCC and through its interaction and compliance with regulation by the Florida PSC, has historically demonstrated excellent Transmission Reliability, and can provide documentation to that effect through FRCC and Florida PSC channels. PEF therefore again asserts that modification or increased stringency in the TPL Standards is not merited. 3. The development of TPL-001-1 stems from a fundamental misinterpretation of the intent of FERC Order 693. NERC for the most part, rather than "clarify" or "consider" various matters raised by FERC, chose to accept all suggestions. Specifically, PEF notes the following misinterpretations regarding Order 693:a) In Paragraph 1692, the Commission agreed with one particular utility's assertion that integrating the four existing TPL Standards into a single standard would be an improvement, and directed NERC to "consider" this. NERC, rather than considering this, formed the SDT, which appears to have spent little considering the issue but rather have deemed it a foregone conclusion that the four existing TPL standards must be abolished and a new standard must be written. b) In Paragraphs 1694 and 1706, the Commission recognizes the significant differences in the various transmission systems, and the impossibility of developing a standardized list of "sensitivities" of critical operating conditions that every Transmission Planner and Planning Coordinator must analyze, regardless of their applicability. The Commission therefore stated that it is reasonable for planning entities to have a means to identify an appropriate range of critical operating conditions, without having to anticipate ?every conceivable critical operating condition.? They furthermore state that their conclusion on the whole matter is that ?only those deemed to be significant need to be assessed?. PEF agrees, and thus is perplexed by the erroneous developments in Requirements R2.4, R2.5, R5.4, R5.5, R2.1.3 and R2.1.4. PEF has

Organization	Question 15:	Question 15 Comments:
		addressed the inadequacies of these Requirements in the answers to Questions 2 and 10. c) In Paragraph 1704, the Commission, amongst other statements, states that they ?are not requiring the construction of additional facilities?. This general statement made by the Commission is demonstrated to be untrue upon examining the realities of the Standard development process. FERC, by directing NERC to consider various clarifications and/or improvements to the TPL Standards, has set in motion a process which will prohibit either Interruption of Firm Transmission Service or the loss of Non-Consequential Load for various outage scenarios, effectively necessitating the construction of redundant facilities. FERC's statement conflicts with the ongoing process in a major way, and PEF respectfully requests that the SDT confer with appropriate FERC personnel to get clarification on this matter. d) In Paragraph 1725, the Commission directs the ERO to modify the planning Reliability Standards to require the assessment of planned outages consistent with the entity's spare equipment strategy. PEF does not disagree with the specifics of analyzing events with respect to spare equipment, except to the extent that the Commission appears to think that such analysis is not adequately covered in the existing TPL Standards. PEF believes that the existing TPL Standards adequately address this issue and all other issues pertaining to the planning of a transmission system. Furthermore, the process is to be followed ?consistent with the entity's spare equipment strategy?, thus deferring to the processes and judgment of the individual Transmission Owners, which calls into question the need to include it in the draft Standard. For additional discussion on this issue, see the answer to Question 5 with regard to Requirement R11. e) In Paragraph 1782, PG&E points out the contradiction that FERC creates in Paragraph 1796 by directing NERC to remove the 2nd sentence of footnote (b). The contradiction also involves key statements made by the Commission in Paragraph 1788. For a more detailed explanation of this contradiction, see the answer to Question 11. f) Paragraph 1794 is part of the Commission Determination section. The Commission states its belief that no TPL Standard should allow an entity to plan for the loss of non-consequential load in the event of a single contingency. The Commission then directs NERC to "clarify the Reliability Standard.", and furthermore state that any Transmission Planners or Planning Coordinators seeking to plan for the loss of non-consequential load in the event of a single contingency can make their comments known through a) filing comments in the standards development process, or b) filing for a regional difference for case-specific circumstances. PEF points out that the Commission merely stated their belief and directed NERC to clarify the Standard. They did not order NERC to change the Standard to reflect its beliefs. NERC, while having the leeway to question FERC's approach in this Paragraph, did not question the approach, but rather deferred to the suggestion in Paragraph 1794 (as well as nearly every other suggestion or request for clarification) that FERC made. PEF is concerned that NERC and the SDT appear to be limiting the extent to which they question or make suggestions to FERC. PEF at present will take the approach of stating the prudency and need to plan for the curtailment of Firm Transmission Service and loss of non-consequential load in the event of a single contingency through the comments process. PEF, however, reserves the right to consider the variance approach or legal approaches, depending on further iterations in the development of the Standard. g) In Paragraph 1795, "The Commission" suggests that the ERO consider developing a ceiling on the amount and duration

Organization	Question 15:	Question 15 Comments:
		of consequential load loss that will be acceptable. If the ERO determines that such a ceiling is appropriate, it should be developed through the ERO's Reliability Standards development process.? To this effect, the SDT drafted Requirement R.3.3.2.1, which at present states ?Consequential Load loss (expected maximum demand and expected duration) following a single Contingency shall be identified in the Planning Assessment.? PEF asserts that this issue is under the jurisdiction of the State Public Service Commissions, who are already doing an excellent job in regulating Consequential Load Loss as part of SAIDI/CMI requirements. FERC and NERC are overstepping their bounds of jurisdiction by attempting to essentially ?double-regulate? an issue that is already adequately regulated via the States. PEF furthermore objects to Requirement R.3.3.2.1 on the grounds that duration of events cannot be estimated with any reasonable degree of accuracy. To handle the challenges of this issue by stating a long-duration worst-case scenario for each outage would be inaccurate, and would tend to foster needless scrutiny and concern on any and all outages associated with Consequential Load Loss. h) In Paragraph 1796, "The Commission" directs the ERO to modify the second sentence of footnote (b) to clarify that manual system adjustments other than shedding of firm load or curtailment of firm transfers are permitted to return the system to a normal operating state after the first contingency, provided these adjustment can be accomplished within the time period allowed by the short term or emergency ratings.? The Commission directed the ERO only to make modifications on the 2nd sentence of footnote (b). The SDT in the draft TPL Standard has eliminated footnote (b) altogether. PEF is surprised and disappointed at the response by FERC to PG&E's very correct assertion that eliminating the allowance of shedding of firm load or curtailment of firm transfers from footnote (b) contradicts the allowance made in footnote (c) regarding C.3 events. FERC's only response was to state that ?manual adjustments referred to in both cases [i.e. Category B and Category C.3 events] apply after the first N-1 contingency?. The fallacy of this statement is that shedding of firm load or curtailment of firm transfers is allowed by footnote (c) for C.3 events, and that every Category B event is by default the first part of a Category C.3 event. PEF asserts that FERC, and consequently the NERC SDT, has created a draft Standard that contradicts direction and suggestion in Order 693 regarding this issue. PEF furthermore asserts that curtailment of Firm Transmission Service or Non-Consequential Load are not valid benchmarks for assessing the reliability of the BES. For additional comments on this issue, see the answer to Question 11. i) Regarding Paragraph 1833, the paragraph in its entirety states: ?MidAmerican states that it supports the proposal to modify TPL-004-0 to require identification of options for reducing the probability or impacts of extreme events that cause cascading. Accordingly, for the reasons cited in the NOPR, the Commission directs the ERO to modify the Reliability Standard to make this modification to the Reliability Standard.? PEF does not understand what FERC has directed on this matter. Furthermore, PEF does not understand the meaning or requirements behind the entire ?Extreme Events? section in the draft Standard, which appears to have resulted from the direction in this particular Paragraph. FERC wants NERC to modify the Standard to ?require identification of options for reducing the probability or impacts of extreme events that cause cascading.? This statement is vague, confusing and does not appear to mandate anything. PEF therefore requests that language in TPL-001-1 to this effect be removed. Furthermore, in Paragraph 1834, the Commission, regarding its preference to expand TPL-004-0 to include analysis of more events such as hurricanes, ice storms, successful cyber

Organization	Question 15:	Question 15 Comments:
		attacks, etc., directs NERC to ?expand the list of events with examples of such events identified above.? This request, similar to Paragraph 1833, does not appear to direct NERC to make specific directions in a Standard. If it was FERC's intent that TPL-004 or its successor be modified to include some or all of FERC's suggested events, and to expand the list further, PEF has many concerns concerning this. The direction in Paragraph 1834 has resulted in the aforementioned Extreme Events section, which contains a note 1 referring to Requirement R3.4. PEF has multiple questions and concerns with the language in this Requirement. The Requirement as worded appears to mandate that Transmission Planners and Planning Coordinators must find the most severe Extreme Event scenarios that can be conceived. Such wording would define any reasonable limit as to which Extreme Events are likely and worthy of analysis, and which are not. Furthermore, many of the events suggested by FERC, such as loss of a large gas pipeline, wildfires, hurricanes, tornadoes, cyber attacks, etc., cannot reasonably be studied. To make any assessment of these events that even approached a level of thoroughness is infeasible, and furthermore has no significant benefit. PEF requests that the SDT point out to FERC that these events cannot be studied, and therefore need to be excluded from any TPL Standard. 4. The main approach of the draft TPL Standard consists of whether to allow or disallow load loss for certain outage scenarios (the most problematic Event categories being P1, P2.2, P2.3, P3, P4, P5 and P6), an approach to which PEF is opposed, and furthermore believes that level of service to retail load is not an issue that NERC/FERC should be regulating. The local utility commissions (the Florida PSC, etc.) have already set in place processes for reviewing/approving the level of transmission built to support the level of service to load, and thus FERC and NERC inappropriately attempt to regulate an issue which the States already adequately regulate. PEF can, and has demonstrated in its internal planning assessments and in assessments performed with FRCC that load curtailment and/or Firm Transmission Service curtailment do not adversely impact the reliability of the BES. In fact, certain post-contingency scenarios can be shown to demonstrate that such curtailments actually promote reliability and a speedier, safer, more efficient recovery of the BES after an event. 5. Several Event categories as presently defined in the draft TPL Standard present outage scenarios on the PEF system for which implementation of redundant transmission facilities would be required, at an exorbitant cost to ratepayers. The redundancy requirements at PEF's 500 kV, 230 kV and 115 kV Substations are numerous, and have not yet been comprehensively quantified, although this analysis is underway. One scenario for which PEF is already certain that redundancy of the 500 kV system would be required is the apparent disallowance of curtailment of Firm Transmission Service or Non-Consequential Load as part of ?System Adjustments? in between the two events of P6. PEF again would point out that no definition of ?System Adjustments? exists at present, and the SDT therefore must define it if compliance is expected. Be that as it may, PEF's 500 kV redundancy projects would clearly cost many billions of dollars, with extremely little benefit. PEF would furthermore point out that this is but one example requiring unnecessary Transmission upgrades, and that further analysis will potentially reveal several more Event categories in Tables 1 and 2 for which additional cost-prohibitive and unneeded projects would be mandated. 6. PEF is surprised and disappointed that neither FERC nor NERC have accepted any responsibility to alert the public or the State and local governments to this process. The public have not been involved in the development of the draft

Organization	Question 15:	Question 15 Comments:
		standard, nor have they been informed that they would bear the financial impact of the increased stringency. In fact, The SDT on p. 369 of the 1st draft Comments Document has stated that ?This is a performance based reliability standard and does not and should not consider economics.? PEF considers this statement to be reckless and irresponsible, and does not accept FERC's and NERC's apparent position that they have no responsibility in this matter. The fact that the draft Standard and FERC Order 693 can be downloaded by anyone from FERC's and NERC's websites does not constitute a sufficient good-faith notice of this process to the public. PEF requests that FERC and NERC specifically address this issue by explaining their failure to involve and inform the public. Assigning this responsibility to each Transmission Planner and Planning Coordinator is not acceptable. FERC and NERC have set this process in motion, and as creators of the process owe an explanation to those who would "foot the bill" for the process. 7. The low voltage threshold of jurisdiction of the draft Standard, previously defined in NERC's definition of the BES as 100 kV, is not specified in the draft Standard. This is a significant misstep by NERC in that a change to NERC's Glossary Definition of the BES, which would ostensibly be done outside the boundaries of this Standard, could profoundly change the requirement for complying with TPL-001-1 without changing a single word of the Standard. PEF is particularly concerned that this Standard must never have jurisdiction over local load-serving transmission systems, regardless of voltage. Any TPL Standard, existing or future, must focus on the reliability of the BES, i.e. the bulk grid, NOT the local load-serving portions of the transmission system. The draft Standard at present does not address this issue at all and leaves Transmission Planners and Planning Coordinators vulnerable to non-compliance with a mere change in the wording of a Definition outside of the Standard. 8. PEF strenuously objects to the allowance of interruption of Firm Transmission Service in Events P1 and P3 for DC lines, while disallowing the same for AC lines. PEF asserts that the determination should be "Yes" for both, and that disallowance for AC lines a) puts DC systems into an elite class of transmission for no explicable reason and b) encourages owners of AC Transmission Systems to replace them with DC, cost concerns notwithstanding. Furthermore, this differentiation fails to recognize or give consideration to the fact that AC systems support Firm Transmission Service; some areas of the AC transmission system carry significant amounts of Firm Transmission Service, and thus a "No" determination for P1 and P3 essentially mandates either implementing redundancy for those parts of the AC system carrying significant amounts of Firm Transmission Service, or severely curtailing Firm Transmission Service on the existing AC systems.

Response: The SAR for this standard recognized FERC orders which indicated a need to "raise the bar" for the industry. The SDT is attempting to do this in a reasonable fashion. There is significant flexibility in the Corrective Action Plans allowed for any additional performance requirements which must be met. Industry consensus, through approval of the SAR, is that revision of the existing TPL standards is appropriate.

1 & 2. Industry consensus, through approval of the SAR, is that revision of the existing TPL standards is appropriate.

3A. The SDT and industry consensus, at this point in the development process, is that consolidation in a single standard is the best course of action. The SDT did not start out with a preconceived idea that there should only be one TPL standard. The SDT started the drafting process by reviewing all of the available

Organization	Question 15:	Question 15 Comments:

documents. This included the existing TPL standards, the SAR, FERC Order 693, and other NERC documents. After reviewing this material, the SDT determined that the majority of the language in the individual standards was in all four of the standards. After much discussion, the SDT determined that the industry would be better served with a single standard instead of staying with four individual standards.

B. Please see the responses provided in questions 2 and 10.

C. The revised TPL-001-1 standard itself does not require construction of additional Facilities although that may be a consequence of application of the standard. Additional operating guides or changes in dispatch are other possible consequences. Footnotes 5 and 10 have been added that provide further clarification regarding interruption of Firm Transmission Service. FERC staff has been available to the SDT for consultation throughout the process.

Footnote 5 - When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

D The SDT has removed Requirement R11 from the proposed standard and Requirement R2.1.4 has been included to help clarify the spare equipment strategy issue.

R2.1.4 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment.

E. Please see response to your comments on question 11.

F. FERC direction provided in Order 693, SDT expertise, and industry input are all being considered in development of the standard.

G. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been removed from the draft.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

H. The SDT is being responsive to FERC direction in paragraph 1796 and agrees that clarification regarding Non-Consequential Load Loss and Firm Transmission Service requirements is necessary. Table 1 specifies the specific events when Loss of Non-Consequential Load is allowed. Footnotes #5 & 10 have been added to the end of Table 1 to explain Firm Transmission Service requirements. Also, please see response to your comments on question 11.

I The SDT believes that the requirement to study Extreme Events in the existing TPL-004-0 must remain in this standard. The SDT has not expanded the number of Extreme Events that must be studied but rather gave examples of how the events may occur. The only significant change in the analysis of Extreme

Organization	Question 15:	Question 15 Comments:
Events is the new requirement for the Transmission Planner or Planning Coordinator to evaluate whether there are cost effective ways to reduce the likelihood or the impact of a particular event and document those findings. The SDT believes that this is a very reasonable approach to ensuring that these major events, even with a small probability, are reviewed and prudent decisions are made. 4. The issues raised on NERC/FERC regulations are beyond the scope of the SDT. However, changes have been made to the 3rd draft of the standard to further clarify the SDT's position on curtailments and service to Loads. Also, Load curtailments are allowed if those customers have signed an Interruptible Load contract arrangement. **Footnote 5 -** the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. 5. The SDT has made the following changes to address the concerns raised by you and others: 1) Added Header note 'e' to the table to show that System adjustments can be made following a single Contingency event, in preparation for the next event; 2) Added footnote 5 to address conditional firm issues, and 3) Added footnote 10 to address re-dispatching resources while continuing to serve firm Load. **Header note 'e' -** For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Footnote 5 -** When the conditions and/or event(s) being studied form the basis for conditional Firm Transmission Service, curtailment of that conditional Firm Transmission Service is allowed. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered. 6. NERC is following the officially sanctioned standards development process with regard to this project just as it follows the process for all standards development work. This is an open, transparent process which has been approved by FERC. Any member of the public is free to participate and/or comment. State regulators are included in the process (Segment 9) and comments are welcome from them just as they are from any other segment of the public or industry. Comments are frequently received from state agencies during the lifetime of a project and two regulatory agencies did provide comments on the second posting. As for the comments on economics, it was not reckless but a statement of fact. However, costs are being considered as should be evident by the questions raised (Q12 thru Q14) in the second posting. The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations.		

Organization	Question 15:	Question 15 Comments:
7. Revisions to definitions in the NERC Glossary of Terms must be approved in accordance with the standards process and issues with application to existing standards would be considered. In addition, each Regional Entity has the ability to establish its own unique definition of the BES. 8 The SDT has removed this differentiation in the Table such that AC and DC lines will be treated equally.		
Lafayette Utilities System	C — Definitely do not support the revised standard	Lafayette's single biggest concern is that the second draft version of TPL-001 imposes performance requirements that are less stringent than those imposed in the previous draft. As the SDT stated in its response to comments on Draft 1: ?The SDT modified the performance requirements relative to Non-Consequential Loss of Load and revised Tables 1 & 2 to add greater detail and provide for more situations where it is acceptable to lose Non-Consequential Load.? This ?watering down? of the standard appears to result from complaints about the costs that certain commenting parties claimed would be necessary to achieve compliance with the performance requirements set forth in Draft 1. This is evident from the SDT's statement in the foreword to the comments form for Draft 2 that the SDT has ?attempted to adjust and clarify the proposed requirements and performance in light of these initial comments,? and that the SDT needs additional information about cost and other compliance issues so that it can ?make more adjustments as appropriate.? Lafayette questions whether it is appropriate for the SDT to shape the performance standards to alleviate certain commenters? cost concerns. The SDT should be focused on developing performance requirements that are judged to be optimal from the standpoint of protecting reliability consistent with sound engineering and planning. Striking a balance between reliability and cost is a policy determination for which responsibility lies elsewhere than in the SDT. Claims that the standards would impose excessive costs are more properly addressed to FERC when the revised TPL-001 is filed for approval because Congress assigned to FERC the responsibility to make judgments of this sort. The SDT should not be ?adjusting? (that is, watering down) the performance requirements in response to transmission owner arguments about the costs of compliance. The dilution of the performance requirements is manifest in a number of elements contained in the proposed draft, including (but not limited to) the following: a) Table 1 (Steady State Performance) would permit the interruption of Firm Transmission Service and the loss of Non-Consequential Load in three P1 (Single Contingency) scenarios involving AC lines. In Order 693 (at paragraph 1794), however, FERC emphasized that loss of Non-Consequential Load in single contingency situations is not permissible. b) Adopting less stringent performance requirements for loss of elements below 300kV may be discriminatory. Most wholesale customer loads are served from delivery facilities that operate at voltages lower than 300kV. The outage of facilities operating at less than 300kV therefore may encompass 100% of a wholesale customer's load, while it is likely to impact a much smaller portion of the total load served by the owner of the affected transmission facilities. Therefore, adopting less stringent performance requirements for facilities operating at less than 300kV would impose a disproportionate burden on affected wholesale customers, as compared to the transmission owner. c) In addition to its potentially discriminatory effect, the notion of imposing difference performance standards based on operating voltage would incent transmission owners to scrimp on needed improvements to lower voltage facilities. Presumably, the distinction originates from a belief that outages on 300kV and lower facilities will have less impact on the

Organization	Question 15:	Question 15 Comments:
		Bulk Electric System. As the August 2003 blackout demonstrated, however, disruptions on lower voltage circuits can cause real and reactive power flow fluctuations across, and eventual separation of, higher-voltage networks. d) Regarding the SDT's elimination of the requirement to re-test cases to ascertain the efficacy of additions included in a Corrective Action Plan (sub-requirement 2.7.2 in Draft 1), it is unclear why this requirement was deleted since very few commenters complained that it would be burdensome. It is hard to see how such a re-testing obligation would impose a significant burden, at least insofar as the steady state analysis is concerned. Eliminating the re-testing requirement seems likely to provide minimal savings, but could be important to verifying that appropriate Corrective Action Plan decisions are made.
Response: There are no intentions by the SDT to "water down" reliability. In fact the SDT has raised the bar in many places; e.g., above 300 kV requirements. Resources and expenditures versus adequate level of reliability are being given due consideration throughout the process and will ultimately be determined by the industry through the ballot process. a Table 1 does *not* permit the interruption of Firm Transmission Service or the loss of Non-Consequential Load in three P1 (Single Contingency) scenarios involving AC lines. b & c. The majority of the SDT believed the 300 kV and higher Systems (EHV) generally represent the backbone of many Systems in the various Interconnections and that the more stringent requirements were appropriate when considering N-1-1 Contingencies of two EHV Facilities. Systems operated above 300 kV generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers where the energy is then delivered by other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. d. The retesting of the cases was deleted due to the SDT believing that this requirement was too burdensome; however, any utility may exceed the requirements listed and perform this retesting if they so desire.		
Arizona Public Service Co.	A —Generally support the revised standard	We generally agree with the Standard as presented so far, but there are numerous issues that still need resolution, Measures, VSLs, Implementation Plan, etc., before WECC can give a full approval of this Standard.
Compliance Elements Development Resource Pool (CEDRP)		With regard to Violation Severity Levels for this standard, the CEDRP doesn't believe the version that has be posted for comment can be commented on from a VSL perspective for two reasons 1) it does not have any measures listed and 2) there are so many "sub-requirements" the VSLs would be quite unmanageable, unless each sub-requirement is of equal importance to fulfilling the objective of the standard. Because there are no measures we can't achieve any insight into importance. The SDT may want to consider trimming the standard down to its most basic elements and providing the details (sub-requirements) in a reference document.

Organization	Question 15:	Question 15 Comments:
Response: Measures, VSL's, and the Implementation plan will be addressed in the next draft of the standard.		
Ameren	C — Definitely do not support the revised standard	From an engineering perspective, the biggest concerns are the additional requirements, including prescribed sensitivity studies, associated with R2 for both steady-state and stability scenarios. We believe that we already cover the needs of our system with the existing NERC standards and Ameren Transmission Planning Criteria & Guidelines. The additional analyses proposed by the revised standard are not warranted and any upgrades indentified by the additional analyses will not provide any significant increase in system reliability. For 2008 compliance, Ameren performed the following steady-state contingency analyses on each of four near-term models and one long-term model:617 Category B single contingencies involving lines and transformers.30 Category B single contingencies involving generators 50 MW and above.1699 Category B single branch outages.135 Category C-1 bus faults. 260 Category C-2 breaker failures.112,575 Category C-3 double contingencies involving lines and transformers.18,510 Category C3 contingencies involving 617 lines and transformers and 30 generating units.73 Category C-5 double-circuit tower outages. For 2008 compliance, Ameren performed 496 stability scenarios of four near-term models and one long-term model: Assuming that we can acquire the qualified manpower, which is presently not available, we estimate that proposed new requirements will increase our compliance activity time by approximately 24 man-months or 2 man-years in a six-month window (January-June) to produce the same quality studies that we produce now. Consequently, we view these proposed additional study efforts as excessively burdensome. Further, we do not see how the additional study work and documentation required by the proposed standard will lead to any significant improvements in reliability. Additional comments: The question of expected Consequential Load Loss magnitude and duration, as specified in R3.3.2.1, is not germane to the reliability of the Bulk Electric System, and is a matter for Distribution Planners and local regulatory authority and is not needed in this reliability standard.
Response: The SDT has received many comments regarding the increased planning requirements to meet the proposed standard. The SDT has reviewed the study work required to comply with the proposed standard as compared to the existing TPL standards. The SDT believes that we have added some additional study work and asked a question about the additional man-hours required to complete any new analysis. However, after this review, the SDT still believes that the requirements for sensitivity studies must remain to document the selection of critical System conditions and study years used in assessing System conditions (see paragraph 1704 of Order 693) and that System conditions are as important as Contingencies in evaluating the performance of present and future Systems (paragraph 1705). The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8. **R2.8** The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.		

Organization	Question 15:	Question 15 Comments:
City of Tallahassee, FL	C — Definitely do not support the revised standard	The requirement regarding non-interruption of firm transmission service in the steady state performance table for Category P1 events does not properly take into consideration the flexibility necessary for utilities with limited interconnections or interconnections with limited transfer capability. This flexibility, which currently exists in the TPL-001 standard (footnote b in the table), allows a utility to curtail firm transactions to prepare for the next contingency. As drafted, in the circumstance where the single element outage in Category P1 was a tie line, even if this line were critical to supporting the transaction (or were required to be in service by the terms of the power contract), interruption of firm service would be a violation of the proposed standard even though such interruption would be either required or appropriate to ensure the reliability of the bulk electric system. For utilities where tie line capacity is constrained or limited, this requirement for Category P1 will require substantial investment in duplicate facilities to ensure that firm transfers would not be interrupted, and the cost of that investment would likely not offer ratepayers a commensurate benefit (presuming such a duplicate facility could even be sited and permitted).For utilities with just a few large generating units (such as a small municipal utility), the requirements for Category P3 in Table 1 set a threshold for compliance that may not be achievable without substantial investment in additional/duplicate transmission facilities and possibly generating units. The concern relates to the restriction about limiting interruption of firm transmission service or non-consequential load following a G-1/N-1 event; the particular scenario is outlined in the bullets below:? Presume a utility with only two large units and some small gas turbines? Under P3, one of these large units is forced out of service? Reserves are called for and delivered along with replacement power using available import capability? Then presume that the N-1 outage in P3 is a major tie line that is critical to the support of the firm power imports? Under the proposed standard, the utility would be unable to curtail the firm purchase or shed any non-consequential load and remain compliant, even though there would be a significant generation/load imbalance & the appropriate response for the reliability of the grid in the region would be to interrupt the transaction and possibly shed load.The flexibility afforded in the existing TPL-001 standard would in fact allow the utility to respond to this event in a more appropriate way while avoiding a very expensive expansion/duplication of facilities (notwithstanding the considerable challenges that the utility would face for siting and permitting of the necessary facilities).
Response: The SDT has made clarifications regarding Firm Transmission Service and Non-Consequential Load Loss. Footnote # 10 has been added to the end of Table 1. The standard does not preclude the possibility of obtaining contractually interruptible load in lieu of system upgrades in the scenario described. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
Florida Power and Light	C — Definitely do not support the revised	The standard, as currently drafted, is unacceptable. Without the ability to curtail firm transfers to prepare for a next contingency, a "super-firm" priority of transmission service is created for non-native load customers. This goes contrary to the intent of the Open Access Transmission Tariff (OATT) that curtailments be comparable and non-discriminatory. – From

<table>
<tr><th>Organization</th><th>Question 15:</th><th>Question 15 Comments:</th></tr>
<tr><td></td><td>standard</td><td>the OATT: – Curtailment of Firm Transmission Service: In the event that a Curtailment on the Transmission Provider's Transmission System, or a portion thereof, is required to maintain reliable operation of such system, Curtailments will be made on a non-discriminatory basis to the transaction(s) that effectively relieve the constraint. If multiple transactions require Curtailment, to the extent practicable and consistent with Good Utility Practice, the Transmission Provider will curtail service to Network Customers and Transmission Customers taking Firm Point-To-Point Transmission Service on a basis comparable to the curtailment of service to the Transmission Provider's Native Load Customers. All Curtailments will be made on a non-discriminatory basis, however, Non-Firm Point-To-Point Transmission Service shall be subordinate to Firm Transmission Service. When the Transmission Provider determines that an electrical emergency exists on its Transmission System and implements emergency procedures to Curtail Firm Transmission Service, the Transmission Customer shall make the required reductions upon request of the Transmission Provider. However, the Transmission Provider reserves the right to Curtail, in whole or in part, any Firm Transmission Service provided under the Tariff when, in the Transmission Provider's sole discretion, an emergency or other unforeseen condition impairs or degrades the reliability of its Transmission System. The Transmission Provider will notify all affected Transmission Customers in a timely manner of any scheduled Curtailments. The SDT has drafted language contrary to FERC specific requirements on comparability. The FERC has consistently directed Transmission Providers to treat all firm transaction on a comparable basis, yet the SDT, in its latest draft is creating a "super-firm" category for only firm transmission service. By creating a higher priority ("super-firm", non-comparable service) for non-native load customers than for native load, native load customers bear a higher cost burden. This and the costs to the ratepayers for negligible increase in already high reliability due to the performance requirements of the standard makes this draft completely unacceptable for FPL to support. FPL will vote against acceptance of this draft standard unless significant changes are made to comport what FPL believes was the intent of FERC Order 693 with regard to the TPL standards.</td></tr>
<tr><td colspan="3">Response: The SDT agrees that clarification regarding Firm Transmission Service and Non-Consequential Load Loss is necessary. Footnote # 10 has been added to the end of Table 1:

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.</td></tr>
<tr><td>Exelon Transmission Planning</td><td>C — Definitely do not support the revised standard</td><td>We appreciate the effort involved in improving this planning standard, and believe in this goal. We are not yet able to support this revised at this time due to the concerns expressed above.</td></tr>
</table>

Organization	Question 15:	Question 15 Comments:
Response: Thank you for your comments.		
CenterPoint Energy and CPS Energy	C — Definitely do not support the revised standard	Without re-iterating previous comments, we will summarize that we find this proposed standard to be an overly prescriptive and unrealistic paper chase that does not add value to the planning process. We also are concerned that this standard demonstrates an unhealthy, one sided approach to planning that does not balance reliability goals against other public policy goals, such as cost and landowner impact.
Austin Energy	C — Definitely do not support the revised standard	The proposed standard is overly burdensome and too prescriptive. It will only result in a marginal improvement in reliability and its primary effect will be to devolve into a paper-chase for auditors.
Response: The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus.		
SRP	B — Unsure about supporting the revised standard	SRP is concerned about what actions will be allowed to meet the higher performance requirements in the transition period and how long will these transition periods last for the different Requirements?
Response: The SDT has developed the Implementation Plan which is included in the 3rd draft of the standard.		
MidAmerican Energy Company	C — Definitely do not support the revised standard	MEC commends the SDT for significantly improving the standard, MEC believes that the standard still must be improved significantly. Probably the most important improvement would be to completely reformat the standard to provide for more organization and clearer VSLs. MEC recognizes that this may result in some initial confusion during the standard writing process, but if such organization results in less confusion over the next decade of applying the standard, the reorganization is well worth it. If the SDT does nothing else, it should reorganize the standard. Here are some suggestions for improvement: R1.1 is not clear. What does this mean? Surely the SDT does not expect that any time the data is modified a rationale is required. Shouldn't this data be updated as necessary? Wouldn't a requirement for providing a rationale each time such changes are made potentially discourage improvements to the models? This requirement should be clarified and limited to a few specific cases that were there are real reliability concerns R2.5.2 - the SDT should revise the material transmission system changes. Addition of a new substation in one of the transmission lines connected to the plant should be revised to specifically refer to a switching station or to a non-

Organization	Question 15:	Question 15 Comments:
		distribution substation. A substation directly serving load is not a good example of a material transmission system change in the context of Generation Unit Stability studies. R2.6.2 - The SDT should revise the material transmission system changes because as presently defined, studies will need to be conducted every year for every year in the assessment period. This is because apparently the SDT has defined any system change as a material change. Since it is rare for there to be a system that does not exhibit some system change from year to year, this will mean ten-year and more studies every year. MEC recommends that the SDT revise this requirement to make clear that only significant system changes are material changes. R2.7.1 - The SDT has written this requirement to include a requirement that the responsible entity must indicate how long Operating Procedures apply. This implies that Operating Procedures should be interim measures. MEC believes that reliability can be maintained with permanent Operating Procedures and recommends that the need to indicate "how long the Operating Procedures will be needed" be deleted from this requirement. R3.3.2.1 - The SDT should delete the need to provide the expected duration of the Consequential Load Loss in this requirement because this requirements a probabilistic calculation and probabilistic planning is not the state-of-the art of the industry. This is reflected in the standard which has been written to continue deterministic planning criteria. As a result, it is a contradiction to require this probabilistic quantity in the middle of this deterministic planning standard. R3.3.2.2 - clarify that the single contingency events are the events in the tab le. R3.4 and R5.4.4 - MEC urges that the SDT delete or revise the words "why the remaining Contingencies would produce less severe System results." Given the expansive nature of the Extreme events it is virtually impossible to comply with this requirement. It is more likely that the responsible entity could show that the more likely and more severe Extreme events were studied. It would be better yet if the SDT would merely require that the responsible entity provide the rationale for the selection of Extreme Events that were studied. R5.5.1 provides an exclusion for changes in individual generating units that require study. Yet R2.6.2 has a broader definition of when Generating Plant Stability is required. These definitions need to be consistent. The definition in R5.5.1 seems to narrow to be a good definition for "material changes." MEC believes that the R5.5.1 should be expanded. Year One definition - MEC suggests that the Standards Drafting Team's (SDT's) Year One definition unnecessarily constrains the time between the completion of assessments as compared to the study period to begin no more or no less than 12 to 18 months. There is no reliability benefits derived by constraining the period between the completion of an assessment and the study period for the next study period. In fact, this may encourage a Transmission Planner to unnecessarily delay "completing" a study just to ensure that the 12 to 18 month requirement is met. For example, lets assume that a Transmission Planner's 2008 Assessment is complete as of May 2008. By the definition of Year One, then the study period for the 2009 Assessment will need to begin from May 2009 through November 2009. This means that the 2009 Assessment must include the 2009-2010 Winter Peak and cannot start with the 2010 Calendar Year. Why??? If a Transmission Planner wants to have a study period that begins with the calendar year, then the Transmission Planner

Organization	Question 15:	Question 15 Comments:
		would need to delay completing the study until July 2009. Why??? What is the reliability benefits for delay??? MidAmerican suggests that the definition of Year One be changed to allow the study period to begin no later than 24 months after the completion of the previous year's study.? Accountability: We suggest that Transmission Service Provider be added because we also suggest that the Transmission Service Provider be responsible for R10.? R2.1 - We suggest that this requirement involves too much study work and we ask that the SDT reduce the number of current studies needed for all subrequirements. ? R2.7.1 - We agree with the requirement, but suggest a slight text change replace "? or Special Protection Schemes,?" with " . . . or Special Protection Systems, . . ."? R2.7.1.1 - We disagree with the "include project initiation date" portion of this requirement. The initiation date is often uncertain and subject to change, which may add considerable work to investigate, monitor and update the date. In addition, we do not know why this information is required to assure BES reliability.? R3.3.2.1 - We agree with the requirement, but suggest a slight text change of: ". . . shall be allowed in the Planning Assessment".? R3.3.2.2 - We agree with the requirement, but suggest a slight text change of: ". . . within their Facility Ratings and within the time period allowed by the applicable time limited ratings.".? R5.4.3.1 - We agree with the requirement, but suggest a slight text change of: ". . . within their Facility Ratings and within the time period allowed by the applicable time limited ratings.".? Table 1? Planning Events ? Header: We suggest that the header be repeated on every applicable page to be more reader-friendly.? Superscripts: The superscripts do not refer clearly to the respective notes (e.g. there are number notes in the beginning of the table, in the extreme events evaluation requirements section, in extreme event description section, and at the end of the table). Perhaps the notes at the end of the table should have unique numbering to make the superscript references clearer.? Shunt device: To avoid the need for future interpretation or clarification, we suggest that the meaning of shunt device be explained or defined somewhere in the standard (e.g. cap bank, inductor bank, SVC, STATCOM, etc.). We need to find out how shunt device outages can (or could in the future) be automatically included in the ACCC routine. We interpret that if each stage of a capacitor bank has a circuit switcher, then the outage would be of the largest cap bank stage.? Extreme Event Evaluation Requirements? 3 Extreme Event Descriptions? 2b & 3b - We agree with the descriptions, but suggest referring to the defined term: "Right-of-Way."?

Organization	Question 15:	Question 15 Comments:
		Note 4 - We agree with the description, but the acronym FACTS should be explained in the standard or a definition be added for "FACTS". Table 2 Header: We suggest that the header be repeated on every applicable page to be more reader-friendly. Other numbering and format changes suggested for Table 1 should also be considered for Table 2.

Response: A. The SDT agrees and has removed the need for documentation of the technical rationale for modification of any data.

B Requirement R2.5 and its sub-requirements have been removed from the proposed standard. Guidelines for the use of past studies to support the Planning Assessment have been added to what is now Requirement R2.5.2. The SDT did not want to be overly prescriptive when describing the type of changes that could be considered material and has left the text general. It is up to the Transmission Planner and Planning Coordinator to provide specificity as to what type of topology changes constitutes a change sufficient to warrant re-evaluation.

R2.5.2 For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

C The SDT does not agree that studies are required for every year of the Assessment period. However, please note that Requirement R2.5 and its sub-requirements have been removed from the proposed standard. Guidelines for the use of past studies to support the Planning Assessment have been added to what is now Requirement R2.5.2. The SDT did not want to be overly prescriptive when describing the type of changes that could be considered material and has left the text general. It is up to the Transmission Planner and Planning Coordinator to provide specificity as to what type of topology changes constitutes a change sufficient to warrant re-evaluation.

D The SDT has retained this requirement and believes that this information should be included in the Planning Assessment.

E To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been removed from the draft.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

F The SDT has deleted Requirement R3.3.2 and has replaced it with additional language in Requirement R3.1 which will hopefully clarify things.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.4.

G. The SDT disagrees with your comment. The SDT believes that this language is needed to ensure that the worst possible situation is studied based on engineering judgment and knowledge of the System.

H. To address industry comments such as yours, Generating Unit Stability is no longer explicitly addressed in the standard and the definitions of Consequential and Non-Consequential Load Loss have been modified.

Consequential Load Loss: ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's~~

Organization	Question 15:	Question 15 Comments:
~~response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed. Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions. **Non-Consequential Load Loss:** Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~. I. The SDT has changed the definition for Year One to accommodate industry concerns. **Year One:** The first year that a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the ~~completion of the previous annual Planning Assessment~~ current calendar year. In response to industry comments, the SDT has removed Requirements R9-R14. R2.1 – The SDT has received many comments regarding the increased planning requirements to meet the proposed standard. However, the SDT believes that the requirements for sensitivity studies must remain to satisfy FERC Order 693. FERC has stated that the sensitivity studies would be used to document the selection of critical System conditions and study years used in assessing System conditions (see paragraph 1704) and that System conditions are as important as Contingencies in evaluating the performance of present and future Systems (paragraph 1705). R2.7.1 (now R2.6.1) – The SDT agrees and had replaced "schemes" with "systems". Installation or modification of Protection Systems or Special Protection Systems R2.7.1.1 (now R2.6.2) - The SDT believes that a project initiation date is an effective measure to track a functional entity's planning and engineering activities and its efforts to provide and maintain a reliable BES. R3.3.2.1 - To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8. R3.3.2.2 - Based on your comment, the SDT has addressed the applicable time-limited rating in what was Header note 'a' for Steady State Only in Table 1 - Steady State & Stability Performance. Requirement R3.3.2.2 has been deleted in favor of Header note 'e' in the revised Table. Please note that the two tables in the second draft have been reduced to one table in the third draft. **Header note 'e' -** For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. R5.4.3.1 - The SDT has deleted Requirement R5.4.3.1. Headers - The SDT also feels that the Tables need to be as clear and concise as possible. To that end, Tables 1 and 2 have been combined into one table with		

Organization	Question 15:	Question 15 Comments:
a revised format. The Planning Events are shown on one page so repeating the headings will not be needed. Superscripts – As part of the change to a single table, the SDT has attempted to clean up various items such as superscripts. Shunt device - The SDT believes that shunt devices are commonly used in the electric utility industry and does not require any further explanation. The SDT recommends contacting the software manufacturer for additional information about the ACCC routine. The SDT believes that the cap bank outage would be based on what elements would need to trip in order to clear the simulated fault condition. Extreme Events - The SDT agrees with your comments and has made the change. The SDT has removed item 3.b. from Extreme Events since this was already covered in Extreme Event 1. **Extreme Event 2b -** Loss of all Transmission lines on a common ~~r~~Right-of-~~w~~Way. Note 4 - The SDT believes that "FACTS" is commonly used in the electric utility industry and does not require any further explanation.		
SERC Dynamics Review Subcommittee	B — Unsure about supporting the revised standard	SERC is in category BA ? Generally support the revised standard ? B ? Unsure about supporting the revised standard ? See three specific concerns below C ? Definitely do not support the revised standard ? 1) Load Modeling is a significant open issue. The models for dynamic studies have yet to be developed and the data is not in hand. This is conflicting with implementation of the TPL standards because modeling details are a gating item to completing some system studies. 2) The proposed sensitivities create significant amount of additional work making the compliance aspect more burdensome and less clear. 3) Category P6 is the loss of a system element, following system adjustments, followed by the loss of another element. The table columns for this category say that interruption of firm transmission service is allowed. The table, however, is not clear whether the interruption of firm service is allowed as part of the system adjustment (between the outages) or whether it is only allowed after the second outage. It was stated in the NERC TPL SDT WebEx that the interruption is not allowed as part of the system adjustment. If this is the interpretation, this will cause many SERC members to not support the revised standard. This would be a dramatic change from the existing standard and would result in the unintended consequence of significantly reducing transfer capability of interfaces to a fraction of their currently reported capability. This would in effect be imposing an n-2 criteria for offering firm transmission service. This would not be an acceptable situation for the users, owners and operators of the bulk power system.
Response: 1. The SDT agrees and believes that industry guidance is needed to capture the appropriate dynamic behavior of Loads. In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. Any comments received from the industry on MOD standards will be forwarded to NERC for inclusion into NERC Reliability Standards Development Projects 2010-04, Modeling Data and 2010-05, Demand Data. Requirement R2.4.1 has been modified		

Organization	Question 15:	Question 15 Comments:
		to clarify expectations regarding load modeling for dynamics studies. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations. **R2.4.1** System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable. 2. The intent of the SDT in requiring performance of sensitivity studies is to identify critical System conditions and to expand planners' portfolio of knowledge about vulnerabilities on their System. This is also an expectation from FERC Order 693 paragraphs 1704 - 1706. Requirement R2.1.3 has been reworded to account for sensitivity studies already performed by the planner. **R2.1.3** For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: 3. The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in the Revision 3 of the Standard provides clarification. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.
MRO NERC Standards Review Subcommittee	C — Definitely do not support the revised standard	While the MRO commends the SDT for significantly improving the standard, the MRO believes that the standard still must be improved significantly. Here are some suggestions for improvement: a. R1.1 is not clear. What does this mean? Surely the SDT does not expect that any time the data is modified a rationale is required. Shouldn't this data be updated as necessary? Wouldn't a requirement for providing a rationale each time such changes are made potentially discourage improvements to the models? This requirement should be clarified and limited to a few specific cases that were there are real reliability concerns. b. R2.5.2 - the SDT should revise the material transmission system changes. Addition of a new substation in one of the transmission lines connected to the plant should be revised to specifically refer to a switching station or to a non-distribution substation. A substation directly serving load is not a good example of a material transmission system change in the context of Generation Unit Stability studies. c. R2.6.2 - The SDT should revise the material transmission system changes because as presently defined, studies will

Organization	Question 15:	Question 15 Comments:
		need to be conducted every year for every year in the assessment period. This is because apparently the SDT has defined any system change as a material change. Since it is rare for there to be a system that does not exhibit some system change from year to year, this will mean ten-year and more studies every year. The MRO recommends that the SDT revise this requirement to make clear that only significant system changes are material changes. d. R2.7.1 - The SDT has written this requirement to include a requirement that the responsible entity must indicate how long Operating Procedures apply. This implies that Operating Procedures should be interim measures. The MRO believes that reliability can be maintained with permanent Operating Procedures and recommends that the need to indicate "how long the Operating Procedures will be needed" be deleted from this requirement. e. R3.3.2.1 - The SDT should delete the need to provide the expected duration of the Consequential Load Loss in this requirement because this requirements a probabilistic calculation and probabilistic planning is not the state-of-the art of the industry. This is reflected in the standard which has been written to continue deterministic planning criteria. As a result, it is a contradiction to require this probabilistic quantity in the middle of this deterministic planning standard. f. R3.3.2.2 - clarify that the single contingency events are the events in the table. g. R3.4 and R5.4.4 - the MRO urges that the SDT delete or revise the words "why the remaining Contingencies would produce less severe System results." Given the expansive nature of the Extreme events it is virtually impossible to comply with this requirement. It is more likely that the responsible entity could show that the more likely and more severe Extreme events were studied. It would be better yet if the SDT would merely require that the responsible entity provide the rationale for the selection of Extreme Events that were studied. h. R5.5.1 provides an exclusion for changes in individual generating units that require study. Yet R2.6.2 has a broader definition of when Generating Plant Stability is required. These definitions need to be consistent. The definition in R5.5.1 seems to narrow to be a good definition for "material changes." The MRO believes that the R5.5.1 should be expanded. i. Year One definition - The MRO suggests that the Standards Drafting Team's (SDT's) Year One definition unnecessarily constrains the time between the completion of assessments as compared to the study period to begin no more or no less than 12 to 18 months. There are no reliability benefits derived by constraining the period between the completion of an assessment and the study period for the next study period. In fact, this may encourage a Transmission Planner to unnecessarily delay "completing" a study just to ensure that the 12 to 18 month requirement is met. For example, let's assume that a Transmission Planner's 2008 Assessment is complete as of May 2008. By the definition of Year One, then the study period for the 2009 Assessment will need to begin from May 2009 through November 2009. This means that the 2009 Assessment must include the 2009-2010 Winter Peak and cannot start with the 2010 Calendar Year. Why? If a Transmission Planner wants to have a study period that begins with the calendar year, then the Transmission Planner would need to delay completing the study until July 2009. Why? What are the reliability benefits for delay? The MRO suggests that the definition of Year One be changed to allow the study period to begin no later than 24 months after the completion of the previous year's study.? Definitions: The MRO agrees with the removal of the "Base Case" definition and

Organization	Question 15:	Question 15 Comments:
		the revisions to the other definitions, except as noted below or elsewhere.? Long Term Planning Horizon definition: The MRO suggests a slight text change of: "Transmission planning period that covers years six through ten. Studies beyond ten years are required to accommodate . . .".? Accountability: The MRO suggests that Transmission Service Provider be added because we also suggest that the Transmission Service Provider be responsible for R10.? Requirements: The MRO agrees with the revisions to the Requirements, except as noted below or elsewhere.? R1.1 - The MRO agrees with the requirement, but would like more description of what to provide in the technical rationale.? R2.1 - The MRO suggests that this requirement involves too much study work and we ask that the SDT reduce the number of current studies needed for all subrequirements. ? R2.6.2 - The MRO agrees with the requirement, but suggest a slight text change of: " . . . short circuit, Generating Unit Stability or System Stability analysis . . .".? R2.7 - The MRO agrees with the requirement, as long as it is really required by FERC Order 693 paragraph 1704.? R2.7.1 - The MRO agrees with the requirement, but suggest a slight text change replace "? or Special Protection Schemes,?" with " . . . or Special Protection Systems, . . ."? R2.7.1.1 - The MRO disagrees with the "include project initiation date" portion of this requirement. The initiation date is often uncertain and subject to change, which may add considerable work to investigate, monitor and update the date. In addition, we do not know why this information is required to assure BES reliability.? R2.7.2 - The MRO agrees with the requirement, as long as it is really required by FERC Order 693 paragraph 1704.? R3.2.2 - The MRO agrees with the requirement, but suggest a slight text change of: "For all BES Transmission lines . . .". ? R3.3.2.1 - The MRO agrees with the requirement, but suggest a slight text change of: ". . . shall be allowed in the Planning Assessment".? R3.3.2.2 - The MRO agrees with the requirement, but suggest a slight text change of: ". . . within their Facility Ratings and within the time period allowed by the applicable time limited ratings.".? R5.1 - The MRO agrees with the requirement, but suggest a slight text change of: ". . . the response of the applicable portion of the BES".? R5.2 - This clarifying requirement should also be included in the steady state and short circuit analysis sections.? R5.3 - The MRO agrees with the requirement, but suggest a slight text change of: ". . . capability of all generators that may have a significant adverse effect on the BES."?

Organization	Question 15:	Question 15 Comments:
		R5.4.3.1 - The MRO agrees with the requirement, but suggest a slight text change of: ". . . within their Facility Ratings and within the time period allowed by the applicable time limited ratings.".? R6 - The MRO agrees with the requirement, but suggest a slight text change of: ". . . shall provide the rationale for and document . . .".? R8 - The MRO disagrees with the requirement, but suggest a text change of: "Each Planning Coordinator shall establish a list of neighboring system and coordinate the distribution of Planning Assessment results among affected entities the listed neighboring systems, coordinating analysis of these results through an open and transparent peer review process."? Table 1? Planning Events ? Header: The MRO suggests that the header be repeated on every applicable page to be more reader-friendly.? Superscripts: The superscripts do not refer clearly to the respective notes (e.g. there are number notes in the beginning of the table, in the extreme events evaluation requirements section, in extreme event description section, and at the end of the table). Perhaps the notes at the end of the table should have unique numbering to make the superscript references clearer.? Shunt device: To avoid the need for future interpretation or clarification, we suggest that the meaning of shunt device be explained or defined somewhere in the standard (e.g. cap bank, inductor bank, SVC, STATCOM, etc.). We need to find out how shunt device outages can (or could in the future) be automatically included in the ACCC routine. We interpret that if each stage of a capacitor bank has a circuit switcher, then the outage would be of the largest cap bank stage.? P2.2 (>300 kV), P2.3(>300 kV), P3 (>300 kV), P4 (>300 kV), P5 (>300 kV), P6 (>300 kV) - This requirement is raising the bar above the existing standards. In the existing standards, this is a Category C event in which load shedding was allowed. A higher criteria for >300 kV may not be appropriate at this time. The new requirement may require the installation of facilities that are costly and have a very long implementation timeframe. We should consider what the cost of this higher requirement might be for ATC and other utilities. If the new >300 kV requirement is not reduced, then we would want the implementation timeframe to be long enough to allow reasonable time to transition from a system built to the old requirement to a system built for the new requirement. The time needed for planning, design engineering, regulatory approvals, and construction of >300 kV facilities can be very long (e.g. up to 10 or more years).? P6 - Why isn't the generator listed as a one of the possible subsequent element outages?? P7 - The MRO disagrees with this requirement. Wisconsin statues require giving preference to using existing ROW for new transmission circuits, but this requirement discourages building multiple circuits on common ROW. Should there be an exclusion in this standard similar to the TLP-503-MRO-1 standard (e.g. could be slightly more than 1 mile due to review?.? Extreme Event Evaluation Requirements? 2 - The MRO agrees with the requirement, but perhaps a definition be added for "System Controls", since one exists for "System Protection".?

Organization	Question 15:	Question 15 Comments:
		3 - The MRO agrees with the requirement, but suggest a slight text change of: "Simulate Normal Clearing unless otherwise specified in the Extreme Event Descriptions."? Extreme Event Descriptions? 2a - The MRO agrees with the description, but suggest a slight text change of: "Loss of a structure or tower line with three or more circuits.."? 2b & 3b - The MRO agrees with the descriptions, but suggest referring to the defined term: "Right-of-Way."? 2e, 3.a.i, & 3.a.ii - The MRO agrees with the descriptions, but how large is "large" and how major is "major"?? 3.a.v - What is meant by successful cyber attack? Is it a type of cyber attack that is documented to have been successful? ? 3c - The MRO agrees with the description, but suggest a slight text change of: "Other events based upon actual operating experience such as:" ? Note 4 - The MRO agrees with the description, but the acronym FACTS should be explained in the standard or a definition be added for "FACTS".? Table 2? 1 - The MRO disagrees with this note. We suggest that it be expanded to include the applicable part as Table 1. "The System shall remain stable. In addition, Facility Equipment Ratings shall not be exceeded. Planned System adjustments are allowed, unless precluded in the Requirements, to keep Facilities within the Facility Ratings, if such adjustments are executable within the time duration applicable to the Facility Ratings."? 3 - The MRO disagrees with this note. We suggest that it be expanded to include the applicable part as Table 1. "Dynamic voltage instability, Cascading outages, and uncontrolled islanding shall not occur."? Between 3 & 4 - The MRO disagrees with omitting Note 4 of Table 1 from Table 2. We suggest including: "Consequential Load and consequential generation loss is allowed for all events shown."? Planning Events? Same comments on Header, Superscripts, and Shunt Device as in Table 1.? Same comments about stricter requirements for P2.2 (>300 kV), P2.3(>300 kV), P3 (>300 kV), P4 (>300 kV), P5 (>300 kV), P6 (>300 kV) as in Table 1.? Same comment about P7 as in Table 1.? Extreme Event Evaluation Requirements? Same comment about Requirement 2 and 3 as in Table 1.? 3 - The MRO agrees with the requirement, but suggest a slight text change of: "Simulate Normal Clearing unless otherwise specified in the Extreme Event Descriptions."?

Organization	Question 15:	Question 15 Comments:
		Notes5 - The MRO disagrees with limiting this requirement to just Category P1 category. We suggest that the synchronism requirement be applied to more categories.

Response: A. The SDT agrees and has removed the need for documentation of the technical rationale for modification of any data.

B Requirement R2.5 and its sub-requirements have been removed from the proposed standard. Guidelines for the use of past studies to support the Planning Assessment have been added to Requirement R2.6.2 (now R2.5.2). The SDT did not want to be overly prescriptive when describing the type of changes that could be considered material and has left the text general. It is up to the Transmission Planner and Planning Coordinator to provide specificity as to what type of topology changes constitutes a change sufficient to warrant re-evaluation.

R2.5.2 For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

C The SDT does not agree that studies are required for every year of the Assessment period. However, please note that Requirement R2.5 and its sub-requirements have been removed from the proposed standard. Guidelines for the use of past studies to support the Planning Assessment have been added to what is now Requirement R2.5.2. The SDT did not want to be overly prescriptive when describing the type of changes that could be considered material and has left the text general. It is up to the Transmission Planner and Planning Coordinator to provide specificity as to what type of topology changes constitutes a change sufficient to warrant re-evaluation.

D The SDT has retained this requirement and believes that this information should be included in the Planning Assessment.

E To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been removed from the draft.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

F The SDT has deleted Requirement R3.3.2 and has replaced it with additional language in Requirement R3.1 while adding Header note 'e' and deleting the reference to single Contingencies which will hopefully clarify things.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.4.

Header note 'e' - For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

G. The SDT disagrees with your comment. The SDT believes that this language is needed to ensure that the worst possible situation is studied based on engineering judgment and knowledge of the System.

H. To address industry comments such as yours, Generating Unit Stability is no longer explicitly addressed in the standard and the definitions of Consequential

Organization	Question 15:	Question 15 Comments:

and Non-Consequential Load Loss have been modified.

Consequential Load Loss: ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed, Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions.

Non-Consequential Load Loss: Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~.

I. The SDT has changed the definition for Year One to accommodate industry concerns.

Year One: The first year that a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the ~~completion of the previous annual Planning Assessment~~ current calendar year.

Accountability - In response to industry comments, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R1.1 – The SDT agrees and has removed the need for documentation of the technical rationale for modification of any data.

R2.1 – The SDT has received many comments regarding the increased planning requirements to meet the proposed standard. However, the SDT believes that the requirements for sensitivity studies must remain to satisfy FERC Order 693. FERC has stated that the sensitivity studies would be used to document the selection of critical System conditions and study years used in assessing System conditions (see paragraph 1704) and that System conditions are as important as Contingencies in evaluating the performance of present and future Systems (paragraph 1705).

R2.6.2 – Based on comments from others, the SDT has removed the requirements for separate Generating Unit Stability analysis and System Stability analysis.

R2.7.1 (now R2.6.1) – The SDT agrees and had replaced "schemes" with "systems".

Installation or modification of Protection Systems or Special Protection Systems

R2.7.1.1 (now 2.6.2) - The SDT believes that a project initiation date is an effective measure to track a functional entities' planning and engineering activities and their efforts to provide and maintain a reliable BES.

R2.7.2 – The old Requirement R2.7.2 has been deleted.

Organization	Question 15:	Question 15 Comments:

R3.2.2 – The Purpose section of the Standard states that this Standard is to develop requirements for the Bulk Electric System, BES.

R3.3.2.1 - To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8.

R3.3.2.2 - Based on your comment, the SDT has addressed the applicable time-limited rating in what was Header note 'a' for Steady State Only in Table 1 - Steady State & Stability Performance. Requirement R3.3.2.2 has been deleted in favor of Header note 'e' in the revised Table. Please note that the two tables in the second draft have been reduced to one table in the third draft.

Header note 'e' - For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

R5.1 & R5.2 (now R4.1 and R4.2) – Most of the industry did not have difficulty understanding that the analysis is limited to the Transmission Planner's or Planning Coordinator's portion of the BES. Therefore, the SDT is not persuaded by your comment to add extra wording.

R5.3 (now R4.3) – The SDT disagrees with the suggested change due to the additional studies that would be required to determine which generators would have an adverse impact.

R5.4.3.1 - The SDT has deleted Requirement R5.4.3.1.

R6 – The SDT believes "define and document" as written are more appropriate than "rationale for and document". The SDT did not revise Requirement R6 (now R5) as proposed – but did make other modifications to this requirement based on other stakeholder comments..

R8 – The SDT has clarified this in a revised Requirement R7.

R7 Each Planning Coordinator shall coordinate the distribution of Planning Assessment results among ~~neighboring systems~~ adjacent Planning Coordinators and any functional entity who has indicated a reliability need, coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890.

Headers - The SDT also feels that the Tables need to be as clear and concise as possible. To that end, Tables 1 and 2 have been combined into one table with a revised format. The headings are repeated on subsequent pages.

Superscripts – As part of the change to a single table, the SDT has attempted to clean up various items such as superscripts.

Shunt device - The SDT believes that shunt devices are commonly used in the electric utility industry and does not require any further explanation. The SDT recommends contacting the software manufacturer for additional information about the ACCC routine. The SDT believes that the cap bank outage would be based on what elements would need to trip in order to clear the simulated fault condition.

P2.2 – The majority of the SDT believed the 300 kV and higher Systems (EHV) generally represent the backbone of many Systems in the various Interconnections and that the more stringent requirements were appropriate when considering N-1-1 Contingencies of two EHV Facilities. Systems operated above 300 kV generally do not directly serve end-use Load customers but rather act as the medium for moving large amounts of power from production to various Load centers where the energy is then delivered by other Transmission or sub-Transmission Systems to end use customers. It is the desire of NERC

Organization	Question 15:	Question 15 Comments:

and various stakeholders that the backbone of the electric power grid be robust and held to a higher degree of reliability. The Implementation Plan will address any need for transition and will be included in the next revision.

P6 – This is already covered in P3.

P7 – The SDT is cognizant of the concerns surrounding the construction of new Transmission lines, including the desire by many to fully utilize existing Right-of-Ways. In its consideration of Footnote 12 (exclusion for common structures less than 1 mile), the SDT considered the impact that this requirement could have on construction of new Facilities. However, after deliberations the SDT believes that the 1 mile exclusion should be maintained for the reliability of the BES and that individual exceptions can be addressed within the NERC process.

Extreme Events 2 - The SDT agrees that "Protection System" is defined in the Glossary of Terms Used In Reliability Standards. However, the SDT believes that these "System Control" issues should be addressed by the NERC SPCTF drafting team.

Extreme Events 3 – The SDT has already included "For all Extreme Events Evaluated" at the beginning of the Evaluation Requirements under Extreme Events.

Extreme Events 2a – The SDT believes that the Extreme Events #2.a. is already sufficient.

Extreme Events 2b & 3b - The SDT agrees with your comments and has made the change. The SDT has removed item 3.b. from Extreme Events since this was already covered in Extreme Event 1.

Extreme Event 2b - Loss of all Transmission lines on a common ~~r~~Right-of-~~w~~Way.

Extreme Event 2e – The SDT suggests that the terms "large", "major", and "successful" be defined between the TP and PC.

Extreme Event 3a – A successful cyber attack would be any attack where an unauthorized person gained access to the systems described in the event.

Extreme Event 3c – The SDT believes that the wording of 3b (was 3c) is already sufficient.

Note 4 - The SDT believes that "FACTS" is commonly used in the electric utility industry and does not require any further explanation.

Tables 2 – As part of the 3rd draft of the revised standard, the 2 tables have been merged into a single table and a general clean-up of the text has been made.

Table 2, note 1 – The SDT has reviewed your comment and feels that your request to add "Facility Equipment Ratings shall not be exceeded. Planned System adjustments are allowed, unless precluded in the Requirements, to keep Facilities within the Facility Ratings, if such adjustments are executable within the time duration applicable to the Facility Ratings." apply to Stability is not appropriate. For the purposes of this standard, Facility Equipment ratings refer to steady state calculated values and planned System adjustments refer to the time frame associated with returning the thermal flow within the applicable steady state Facility Rating.

Table 2, note 3 – The SDT agrees with your comment on making general note 3, located at the beginning of Table 1, "Voltage instability, cascading outages, and uncontrolled islanding shall not occur" applicable to both Steady State and Stability and has made that change in the next version.

Note 4 – The SDT also agrees that the general note 4, at the beginning of Table 1, applicable to both Steady State and Stability and has made that change in the next version.

<table>
<tr><th>Organization</th><th>Question 15:</th><th>Question 15 Comments:</th></tr>
<tr><td colspan="3">Note 3 – The SDT has already included "For all Extreme Events Evaluated" at the beginning of the Evaluation Requirements under Extreme Events.

Note 5 – The SDT also feels that the synchronism requirement should apply to more than just the P1 Category but under certain conditions. As stated in Note 1.a.ii, for planning events other than P1, no generating unit or units totaling more than the Contingency reserve of the Balancing Authority shall be allowed to pull out of synchronism. If less than the Contingency reserve, then the resulting apparent impedance swings must not pass through relay characteristics that would result in the tripping of any Transmission System elements other than the generating unit and its direct connection Facilities</td></tr>
<tr><td>Modesto Irrigation District</td><td>B — Unsure about supporting the revised standard</td><td>Concerns about the following: attempt to introduce interconnection stability studies into TPL studies, and redefinition of Consequential and Non-Consequential Load Loss.</td></tr>
<tr><td colspan="3">Response: The SDT believes that there is no significant distinction between generator and System Stability and has modified the definitions and Requirements R2, R2.6.1 (now R2.5.1), R2.6.2 (now R2.5.2), R5 (now R4), and R5.5 (now R4.4) in the third draft.

R2 Each Transmission Planner and Planning Coordinator shall ~~conduct and document the results of~~ prepare ~~its~~an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, document results, and shall cover steady state analyses, short circuit analyses, and Stability analyses ~~including both System and Generating Unit Stability~~.

R2.5.1 For steady state, short circuit, or ~~System~~ Stability analysis: the study shall be five calendar years old or less.

R2.5.2 For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~

R4.4 ~~At a minimum, t~~Those Planning Event Contingencies in Table ~~2~~1 – ~~Stability Performance~~ that ~~would~~are expected to produce more severe System impacts shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information with an explanation of why the remaining Contingencies would produce less severe System results.

In response to numerous concerns, the following changes were made to the draft standard regarding Consequential and Non-Consequential Load Loss</td></tr>
</table>

Organization	Question 15:	Question 15 Comments:
definitions. **Consequential Load Loss:** ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed, Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions. **Non-Consequential Load Loss:** Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction. ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~.		
Arkansas Electric Coop. Corp.	B — Unsure about supporting the revised standard	I have a growing concern that the NERC Reliability Standards are not going far enough to ensure adequate and reliable service to customers and users of the BES. Each revision of the standards seem to be driven by the need to preserve the integrity of the grid and preventing cascading blackouts but stop short of ensuring that load continues to be served under contingency conditions and adequate grid capacity is available. For the customers and end users of the system if their load is allowed to be dropped or can not be served because of the lack of capacity then the BES is not reliable. The definitions of Consequential Load Loss and Non-Consequential Load Loss concern me the most. How these definitions are then applied in the tables is also a great concern. Hopefully my previous comments to the other questions in the comment form provide explanation. Another concern I have is the fact that I tried to provide comments last fall to draft 1 of the standards and they were not allowed. After following the instructions provided I provided my comments before the deadline. I later discovered they were not posted. After repeated attempts asking NERC to determine why my comments were not received and posted and showing evidence that they had been provided by the deadline, the only response I received was pretty much "sorry Charlie". Mistakes happen. NERC should be big enough to admit when they make a mistake instead of just blowing them off. I have no way of knowing if or how many times this may have happened before. I am not trying to say that anything malicious was intended, however it does leaves me with concern that fair treatment is being given to all comments and cast a shadow over confidence in the standards approval process.
Response: The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT believes that your concerns are mostly addressed by the revised Table 1 - Steady State and Stability Performance, along with the revised definitions of Non-Consequential Load Loss and Consequential Load Loss in the updated draft of TPL-001 standard. **Consequential Load Loss:** ~~Load that is no longer connected to a source as a result of the event being studied or which is lost as a result of the load's response to the transient conditions of the event (other than through the action of UVLS or UFLS schemes). Although Load which is lost as a result of the Load's response to the transient conditions of the event is considered Consequential Load Loss and is permitted when Consequential Load Loss is allowed,~~		

Organization	Question 15:	Question 15 Comments:
~~Transmission planning entities are not allowed to rely upon the expectation of such Load loss to meet steady state performance requirements.~~ All Load that is no longer served by any Transmission Facilities as a result of the Facilities being removed from service by a planned Protection System operation to isolate fault conditions. **Non-Consequential Load Loss:** Non-Interruptible Load loss other than Consequential Load Loss, Supplemental Load Loss, and Load Reduction.~~.~~ ~~For example, non-Interruptible Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems would be considered Non-Consequential Load Loss~~. Comments from AECI were included in the responses to the comments from the first posting. Please go back and review the posted comment form.		
Midwest ISO	C — Definitely do not support the revised standard	We appreciate the hard work of the SDT and understand the difficulty of this task. We applaud the efforts to improve the standard. However, in its present state, in general the revised standard fails in one if its primary stated goals: create a "clear and concise standard". While some of the ideas are an improvement, overall the standard is very meandering and it makes it difficult to figure out what the requirements are for a particular analysis type without flipping back and forth between the scattered requirements. For example R2 addresses various aspects of both Near and long term studies, steady state, short circuit, stability, on peak, off peak and other topics. Then there are separate sections (R3, 4, 5) that speak to the various analysis types again. It probably makes sense to the SDT that has evolved with the drafts and discussions, but when you pick it up it is very confusing. One thing that would help greatly would be to label the major Requirements sections to convey the organization of the document. If the SDT made a topical outline of the standard by major Requirement this could help the team organize the standard better. Resulting topical headers may look something like the following for example, R1: ModelingR2: Study Types and Assessment RequirementsR3: Steady State Analysis MethodsR4: Short Circuit Analysis Methods?R5: Stability Analysis Methods Etc. If it has not been done (and it looks like it has not), the SDT should consider having the language reviewed by the NERC or other legal team. Language that seems clear to experienced engineers may not be precise as is critical for standards that carry monetary penalties. An independent review by a non-engineer lawyer would help greatly. Of course, the SDT would then have to undo some damage that would undoubtedly be done to context by the lawyers - but the pass through legal would be a good step.? ? Other concerns:? P5 requires testing for a single component failure within a Protection System. What is this referencing? How can a PC/TP be expected to be intricately aware of protection systems and effects of single component failures? Under 2.7.2, there is a generic requirement to expand a list of possible corrective actions under 2.7.1 for any sensitivities under R2.1.3, 2.1.4, 2.4.3 and 2.4.4. This is very open ended and subject to interpretation. How can an auditor review such requirements with consistency?
Response: The SDT has attempted to make the latest draft more clear and concise - such as condensing Table 1 and 2 into a single table. The SDT has considered having headers/labels in the document and these are strongly discouraged by NERC's legal staff. The overall format of the tables has been modified to make it more reader friendly. NERC is following the officially sanctioned standards development process with regard to this project just as it follows the process for all standards development		

Organization	Question 15:	Question 15 Comments:
work. This is an open, transparent process which has been approved by FERC. Review and comment by any entity's legal staff is welcome, but not a required part of the process. The description of the P5 event has been clarified in draft 3 to address your concern. Requirement R2.7.2 has been removed. The SDT has modified Requirement R2.7 (now R2.6) to clarify that Correction Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. **R2.6** For Planning Events shown in Table 1~~ – Steady State Performance and Table 2 – Stability Performance~~, when the analysis indicates an inability of the System to meet the performance requirements in ~~the t~~Tables~~s~~ 1, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall:		
Tri-State Generation and Transmission Association, Inc.	A — Generally support the revised standard	We appreciate the efforts of the SDT, considering the difficulty of the task that was and is before them. Our biggest concern is potential confusion regarding sensitivity studies. Secondly, we absolutely must make the Performance Table completely clear and concise. Additional work now will pay big dividends later. Thirdly, there is some ambiguity of several terms used in the Standard that prevents exact interpretation of significant portions of the Standard. Here are a few additional comments we hope the SDT will find helpful: It may simplify considerations of assessments and modeling work to define ?assessment? as including written documentation. Then the Standard would not need to separately include "and shall include written documentation" in the body of the standard titles. Also, the SDT should make it clear that "assessment" is what is required; that annual re-study analysis may not necessarily be required. Thanks to the SDT for keeping this feature. It will greatly simplify our work, and should speed the audit process as well. There seems to be some ambiguity between either 1) requiring specific years to be studied and 2) leaving timeframe selection to the TP. Assessment for year One or Two (R2.1.1) may be performed by either the TOP or the TP. Studies of year One or year Two are generally considered to be operating studies and should probably not be required in TPL-001-1. Also in R2.1.1, year Five is specified as a required study year. No matter what the requirement says, the TP will need to assess performance for critical timeframes. This would lead to additional study if year four were the critical year for example. And for sensitivity studies of delayed facilities (R2.1.3.3) additional study years might be required. Perhaps a reasonable compromise would be to require something in the 2 to 5-year timeframe, and something in the 6 to 10-year timeframe. For coordination with regional study groups in our area, one would logically choose year 5 and year 10, but the specific choice should be up to the TP (and PC if any). Sole-Customers on radial service who are responsible for facility upgrades should be allowed to elect a lower reliability

Organization	Question 15:	Question 15 Comments:
		than the rest of the system. It seems that operating scenarios required to be studied by TOP should not need study in the planning horizon by the TP, and should be excluded from this standard. Specific comments concerning other sections of the draft standard: 1. In the definition of Generating Stability Study, we suggest "the lack of damping" be changed to "damping" 2. In R2.1 title, please move listed requirements in the second sentence to sub-requirements (they are already there). 3. In R2.1 title sentence, the term "annual current" presents two additional requirements. We suggest those words be deleted. 4. In R2.1, delete the end of the title sentence, ending the sentence with "the following studies" 5. In R2.1.3.2, the meaning of "transfer" is not clear. 6. In R2.1.3.4, the term "variability" is not clear. do you mean "Operating Capability"? 7. In R2.1, R2.2 and 2.4, the phrase "Near Term (or Long Term) Transmission Planning Horizon portion of the" could be omitted. "Near Term" and "Long Term" study horizons should just be specified as sub-requirements of Steady State, Stability, and Short Circuit 8. In R2.7.3, the term "identified System Facilities" is not clear. System Additions? 9. Heading R3.3 is not needed. Renumber section sub headings to 3.2.3, etc.

Response: In response to industry comments regarding sensitivity studies, the SDT has made changes to Requirements R2.1.3 and R2.4.3 and each of their sub-requirements to clarify expectations related to sensitivity studies.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

The SDT also feels that the Tables need to be as clear and concise as possible. To that end, the next version will combine Tables 1 and 2 into one table with a revised format.

The SDT crafted the definition of Planning Assessment using the term "documented" instead of "written" such that an assessment can be either in written or

Organization	Question 15:	Question 15 Comments:
electronic format. Requirement R2 states that the assessment is to be performed annually. The SDT chose the Year One definition such that this would be out of the operational planning horizon and into the planning horizon. The SDT chose the years to be studied such that both the Near-Term and Long-Term Planning Horizons would be adequately studied and has not seen a sufficient number of comments to warrant changing the requirements. . Sole-customers who are responsible for facility upgrades are allowed to elect lower reliability than the rest of the system if those customers have signed an Interruptible Load contract arrangement. The SDT believes that all significant probable Contingencies over a wide range of operating conditions should be studied. 1. The definitions for both Generating Unit Stability Study and System Stability Study have both been removed and these Stability areas have been combined into just one Stability area. 2, 3, and 4. The SDT disagrees with the proposed changes and believes that compliance with Requirement R2.1 can be shown through the use of both current and past studies. 5. The SDT believes that "transfers" is generally understood to mean electric power that is transferred or moved from one area to another, and as such, has not added a definition of transfers. 6. The SDT has revised the language to replace "variability" with reactive resources "capability". ~~Variability and outages of r~~Reactive resource~~s~~ capability. 7. The SDT believes that the format and the language of these requirements are appropriate and no additional changes are needed. 8.,The SDT received only a single comment regarding use of the terms "identified System Facilities" and therefore believes the proposed language is clear and appropriate. "Identified System Facilities" are those new or modified facilities which were identified in previous Corrective Action Plans. 9. Requirement R3.3 has been removed and replaced with additional language in Requirement R3.1. **R3.1** Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~— Steady State Performance.~~ based on the lists created in Requirement R3.5.		
Lakeland Electric	B — Unsure about supporting the revised standard	Curtailing firm transmission should explicitly be a viable option when preparing for the next contingency if the previous contingency and a credible next contingency call for curtailing firm transactions for reliabilities sake. Not allowing for firm transmission curtailment in this case seems to be a market requirement driving a reliability requirement. Determining the duration of consequential load loss (R3.3.2.1) is impractical as the root cause of the event vice the defined event type (e.g. - loss of line) determines the duration of the outage. A line can be outaged by a temporary lock out of protection device or 15 spans of a line might be destroyed by fire. The difference between the two make determination of duration impractical.

Organization	Question 15:	Question 15 Comments:
		System peak Load (R2.1.1) needs to specify if it is the specific year, season or historical peak demand. Forecasting methodologies affect the system peak load that is projected. Differences between a 50/50 and 80/20 case will result in different forecast peak data.

Response: Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for Event P1. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted Interruptible Loads, in preparation for the next Contingency.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

To meet industry concern as well as FERC Order 693, the SDT has added Requirement R2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been removed from the draft.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

The SDT intentionally provides flexibility for the Transmission Planner/Planning Coordinator to decide which Load forecasting methodology to use. The required studies and sensitivity analysis ensures that sufficient study is performed to cover an appropriate range of System conditions.

Organization	Question 15:	Question 15 Comments:
Southern Company Transmission	C — Definitely do not support the revised standard	Category P6 is the loss of a system element, followed by system adjustments, followed by the loss of another element. The table columns for this category say that interruption of firm transmission service is allowed. The table, however, is not clear whether the interruption of firm service is allowed as part of the system adjustment (between the outages) or whether it is only allowed after the second outage. It was stated in the NERC TPL SDT WebEx (August 26, 2008) that the interruption is not allowed as part of the system adjustment. If this is the interpretation, this will cause Southern Company to not support the revised standard. This would be a dramatic change from the existing standard and would result in the unintended consequence of significantly reducing transmission system capability to accommodate firm transmission service including reduction of transfer capability of interfaces to a fraction of their currently reported capability. This would in effect be imposing an n-2 criteria for offering firm transmission service. This would not be an acceptable situation for the users, owners and operators of the bulk power system. In addition, the standard should clarify the accommodation of Conditional Firm Service as defined by FERC Order 890.

Response: The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is

<table>
<tr><th>Organization</th><th>Question 15:</th><th>Question 15 Comments:</th></tr>
<tr><td colspan="3">necessary. Footnote 10 in draft 3 of the Standard provides clarification.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled ‘Initial System Conditions’) and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner’s planning region are relied upon, Facility Ratings in those regions must be considered.</td></tr>
<tr><td>Brazos Electric Power Cooperative, Inc.</td><td>C — Definitely do not support the revised standard</td><td>Our biggest concern is the apparent lack of experience or understanding in the repercussions of including so many required studies and detailed documentation. And to what end? The amount of data that would be required to be saved will be so voluminous no one could go through it all to make any meaningful determination in a timely fashion. It's one thing to study every possible combination of outage but you then have to do something with the results, not just record them somewhere because a standard requires it.

On the other hand some progress is being made in removing some of the more ambiguous or useless items so we are getting there to some degree. Deleting 1.1.2, 1.1.3, 2.7.3, 2.7.4, and 5.4 are good starts. However it appears some things were added that are just confusing or are unnecessary.

5.5.2 seems to simply restate the obvious intent of the section, to meet the performance requirements so its not really needed.

Phrases such as "document why categories were NOT selected" are intuitively obvious. Categories were not selected because, in the judgment of the TP or PC, they were not deemed useful to study so why document this each time.

R6 is also a confusing addition to this Standard and we aren't sure what it's intended to require. Use of the word "proxies" is probably not the best substitute for what was intended. We suggest R6 be deleted as well.</td></tr>
<tr><td colspan="3">Response: The SDT has received many comments regarding the increased planning requirements to meet the proposed standard. However, the SDT believes that the requirements for sensitivity studies must remain to satisfy FERC Order 693. FERC has stated that the sensitivity studies would be used to document the selection of critical System conditions and study years used in assessing System conditions (see paragraph 1704) and that System conditions are as important as Contingencies in evaluating the performance of present and future Systems (paragraph 1705). Neither FERC, nor the SDT, believes that every possible combination outage needs to be analyzed for every System condition, but FERC expects those that produce the most severe reliability impacts should be documented (paragraph 1706).

In response to industry comments, Requirement R5.5 has been deleted since Generating Unit Stability is no longer explicitly addressed in the standard.

The SDT agrees and has deleted the phrase from Requirements R2.1.3 and R2.4.3.

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical~~</td></tr>
</table>

Organization	Question 15:	Question 15 Comments:
~~rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: The industry did not seem to find usage of "proxies" in Requirement R6 (now R5) unclear or confusing. Therefore, the SDT has determined that no change to Requirement R6 is needed with regard to the use of proxies.		
LCRA TSC	A — Generally support the revised standard	LCRA had a comment on the first posting stating that the loss of any two Transmission circuits on a common structure should be viewed as a single contingency as a single component failure (tower, shield wire, conductor, hardware) could in-fact lead to the loss of two circuits. In the second draft, this outage is still being viewed as a Multiple Contingency (P7). At the same time, the loss of a tower line with three or more circuits is being viewed as an Extreme Event, when the same single failure could lead to the loss of multiple circuits. So, even if a double circuit outage is viewed as a Multiple Contingency, shouldn't a multiple circuit outage be viewed the same. In the Definitions of Terms Used in Standard, Extreme Event is defined as Events which are more severe and have a lower probability of occurrence than Planning Events. What is a "lower probability of occurrence"? Is this to be determined by each TP or TO? How is this probability determined? Are we to assume from this definition that we can use probabilistic planning to determine which Events should be studies even at the N-1 level?
Response: The SDT does not believe that the loss of a tower line with three or more circuits is similar in probability to two circuits on a common structure. Therefore, it is appropriate to classify the events differently. The SDT views "lower probability of occurrence" events as those events that occur much less often than Planning Events. The SDT does not intend for this probability to be determined by each utility. The SDT desires that Extreme Events be studied - but do not necessarily have to have Corrective Action Plans.		
NERC and Regional Coordination	C — Definitely do not support the revised standard	Changes should be made to the sensitivity analysis. See question 10 above. R2.6 - The need to restudy previously studied years should be left to the transmission planner when in their judgment there is a material change. Based on the material change the TP should be responsible for determining what aspects of the performance requirements need to be proven
Response: Please see the response to question 10. The SDT believes that past studies must be five calendar years old or less to be relevant and the associated models should not have had material changes. Requirement R2.5 and its sub-requirements have been removed from the proposed standard. Guidelines for the use of past studies to support the Planning Assessment have been added to what is now Requirement R2.5.2. The SDT did not want to be overly prescriptive when describing the type of changes that could be considered material and has left the text general. It is up to the Transmission Planner and Planning Coordinator to provide specificity as to what type of		

Organization	Question 15:	Question 15 Comments:
topology changes constitutes changes sufficient to warrant re-evaluation. **R2.5.2** For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:		
IESO	A — Generally support the revised standard	(i) We generally support the direction and principle of the revised standard. It is a step in the right direction to more clearly stipulate the types of events and expected performance requirements with inclusion of multiple element contingencies and multiple single contingencies, and allowance for interruptions to firm transmission services and non-consequential load loss. (ii) More details and refinements are expected to be provided that address the issue of sensitivity testing, reduce the number of layers in the subrequirements (to facilitate ease of developing Measures and Violation Severity Levels), more clearly specify the responsible entities, etc. We look forward to seeing these improvements in the next revision, along with the first draft of Violation Risk Factors, Time Horizons, Measures, Data Retention Periods, and Violation Risk Factors when the requirements approach their near final draft form. (iii) We suggest the SDT review the development plan with the Standard Process Manager, especially the timing for posting the standard for balloting, responding to comments and conducting recalculating ballot. The timing between the initial ballot and recirculation ballot is usually short, and the balloted standard is not supposed to change. The proposed development plan appears to allow a long lead time between the two ballots, and for making changes to the standard between them.
Response: i. Thank you for your comments. ii. The SDT has streamlined the document and the tables to add clarity and has added the elements that were missing from the previous drafts. VRF, tec., have been added to the 3rd draft. iii. All development plans are reviewed with the Process Manager prior to finalization as per established procedure.		
North Carolina Electric Membership Corp	B — Unsure about supporting the revised standard	While we are satisfied that the changes are moving in the right direction, we share concerns that are being expressed by other SERC TPs and PCs that the standard may be overly prescriptive in some areas such as the sensitivities being required.
Response: The SDT agrees and has clarified the language to allow the Transmission Planner and Planning Coordinator to choose the sensitivities (Requirements R2.1.3 & R2.4.3).		

Organization	Question 15:	Question 15 Comments:
R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment: **R2.4.3** For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, ~~s~~sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:		
E.ON U.S. Transmission Planning	C — Definitely do not support the revised standard	It is confusing that single Contingency and multiple Contingency are used throughout the document when the Categories in Tables 1 and 2 are Single Contingency and Multiple Contingency. Also System normal, normal conditions and Normal System are spread throughout the document. If they all mean the same, use the same wording. If not, explain the difference. R2.4.1. - Does this apply only to motors directly connected to the BES? Is there a size (hp/MW) limit? Who is responsible to provide this data to the Planning Coordinator? I would think it would both the Distribution Providers or the Generator Owners but R9 & R12 do not mention this. R2.4.1 refers to ?the dynamic behavior of Loads? and induction motor loads. How would this model data be developed, and by who? R2.5.2. - Define “Material”. Is an addition of a load tap point material? R2.6.2. ? Define ?study area?. Does a topology change over 300 miles away trigger a stability study for a generating plant? R2.7.1.1. ? Define ?project initiation date?. Would this include going to the PSC to get approval or just when construction begins? R3.2.1 states ?? and identify how the generators are treated in the steady state simulation.? What is meant by ?treated?? I request the use of more descriptive wording. R3.2.2 states ?? and identify how loadability is treated in the steady state simulation.? What is meant by ?treated?? I request the use of more descriptive wording. R3.3.1 “System normal” is a Planning Event included in Table 1. R3.3.2 capitalize ?Single? if you referring to P1 and P2 events. If not, this is confusing. R3.3.2.1 states ?Consequential Load loss (expected maximum demand and expected duration) following a single Contingency shall be identified in the Planning Assessment.? Quantification of expected duration requires a probability analysis of load cycles, repair time, and potentially of other factors that will be difficult, if not impossible, to develop with any confidence. The Planning Assessment is based on a deterministic evaluation. Requiring the expected duration is

Organization	Question 15:	Question 15 Comments:
		inconsistent and useless. R3.3.2.2 Is this the intent? ? Following Single Contingency events, Transmission configuration changes and redispatch of generation can be simulated to return the system to Normal Rating provided that all Facilities shall be operating within their Emergency Rating. R5.3 states ?? and identify how the generators are treated in the simulation.? What is meant by "treated"? I request the use of more descriptive wording. R5.5.1 and R5.5.2 should be moved to 2.5. These requirements outline the generators and the sensitivities to be analyzed. R5 appears to focus on Tables 1 and 2. R5.5.2 states ?Shall be performed for changes in the real power output?? What types of ?changes?, or ?changes? due to what? Is intention of the requirement, that Generating Unit Stability be assessed at two levels of real power output that differ by more than 10% of the existing capability or more than 20 MW, whichever is greater? R6 states ?? and document the proxies used in the simulation?.? What is meant by ?proxies?? I request the use of more descriptive wording. R8 ends with ?This distribution shall include:? Include what? Table 1 There used to be limits on multiple circuit towers and common ROW greater than 1 mile. Is this left to the Transmission Planner and Planning Coordinator ? Extreme Events ? Item 3b is the same as Item 1, this should be removed. Table 2 Note 5.a.ii How can this be applied when the largest unit in the Balancing Authority Area is larger than the contingency reserve of the Balancing Authority. This requirement is excessive. At some level, subsequent trips of generators and/or lines should be allowed as long as Cascading does not occur.

Response: The row headers are capitalized in the Table. Please note that the two Tables have been changed to just one Table in this draft.

R2.4.1 – The SDT does not believe the requirement applies only to motors directly connected to the BES, nor is there a specific hp/MW limit. In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R2.4.1 – Requirement R2.4.1 has been modified to clarify expectations regarding load modeling for dynamics studies.

R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic

Organization	Question 15:	Question 15 Comments:

behavior of the Load is acceptable.

R2.5.2 – Requirement R2.5 and its sub-requirements have been removed from the proposed standard.

R2.6.2 (now R2.5.2) –The SDT believes that it is up to the Planning Coordinator and Transmission Planner to define the study area and to determine which System changes could impact the study area

R2.7.1.1 (now R2.6.2)– The SDT has not defined a project initiation date and will leave that definition to be determined by the Transmission Planner and Planning Coordinator.

R3.2.1 – "Identify how generators are treated" means that you identify at what voltage you would believe that the generator would trip. Any time you run a dynamic simulation or a steady state simulation and you don't trip the generator, you are implicitly assuming that it will ride through the voltage excursion obtained in the simulation. The requirement is to identify what you are assuming for voltage ride-through criteria for the generators you have modeled.

R3.2.2 – The SDT has changed ‘treated’ to analyzed’. .

R3.3.2 For all generators, studies shall consider the minimum steady state voltage limitations ~~of all generators~~ and identify how the generators are ~~treated~~ analyzed in the steady state simulation.

Requirement R3.3.1 has been removed and replaced with additional language in Requirement R3.1.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.5.

R3.3.2 – This requirement was deleted.

R3.3.2.1 **-** To meet industry concern as well as FERC Order 693, the SDT has added Requirement R2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

R3.3.2.2 - Based on your comment, the SDT has addressed the applicable time-limited rating in what was Header note 'a' for Steady State Only in Table 1 - Steady State & Stability Performance. Requirement R3.3.2.2 has been deleted in favor of Header note ‘e’ in the revised Table. Please note that the two tables in the second draft have been reduced to one table in the third draft.

Header note ‘e’ - For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

R5.3 - The SDT agrees that the word "treated" is vague and has revised Requirement R5.3 (now Requirement R4.3.2) and Requirement R3.2.2 (now R3.3.3) to clarify the requirement.

Organization	Question 15:	Question 15 Comments:
R3.3.3 For all Transmission lines, studies shall consider relay loadability and identify how loadability is ~~treated~~ analyzed in the steady state simulation. **R4.3.2** ~~Studies shall consider~~ Simulate generator performance under anticipated conditions including how the voltage ride through capability ~~of all generators and identify how the generators are treated~~ is analyzed~~in the simulation~~. R5.5.1 & R5.5.2 - In response to industry comments, both Requirement R2.5 and Requirement R5.5 have been deleted since Generating Unit Stability is no longer explicitly addressed in the standard. R6 (now R5) - Most of the industry did not find usage of "proxies" in Requirement R6 unclear or confusing. Therefore, the SDT has determined that no change to Requirement R6 is needed with regard to proxies. R8 - The incomplete sentence was a typo and has been deleted from Requirement R8. Footnote 12 has been added to Table 1 to address your comment on the exclusion criterion for multiple circuit towers. **Footnote 12** - Excludes circuits that share a common structure for 1 mile or less. The SDT agrees with removing the redundancy found with Extreme Event 3.b. Please see footnote 1.a.ii for clarification. **Footnote 1.a.ii -** For all other Planning Events: No generating unit or units totaling more than the Contingency ~~r~~Reserve of the Balancing Authority (or Reserve Sharing Group if applicable) shall be allowed to pull out of synchronism. Generators that pull out of synchronism must have out-of-step protection or some other means to trip the generator for this condition and the resulting apparent impedance swings must not pass through relay characteristics that would result in the tripping of any Transmission System elements other than the generating unit and its direct connection Facilities.		
ERCOT System Planning	C — Definitely do not support the revised standard	The NERC reliability standard requirements should represent the minimum studies necessary to achieve reliability given the broad range of entities of various sizes and capabilities. Instead, the standards seem to represent the gold standard of the kind of studies that could be accomplished (steady-state, short circuit, and stability) given infinite time and resources with the number and variety of contingencies and sensitivities necessary. This level of steady state and stability studies can only be undertaken by the larger entities with a deep and experienced engineering staff. Why are most of the requirements applicable to a Transmission Planner and Planning Coordinator? Unless they are the same entity, this is an unnecessary duplication of effort. If a Planning Coordinator has a number of Transmission Planners in its region, then these requirements have to be fulfilled by each Transmission Planner for its individual area and the Planning Coordinator for the region made up of the individual areas? What is the Planning Coordinator coordinating if it is duplicating the work of the Transmission Planner?
Response: The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations. This standard does not represent the gold standard, but rather the SDT is developing a standard based on consensus industry support.		

Organization	Question 15:	Question 15 Comments:
The SDT recognizes that the Transmission Planner and Planning Coordinator must work closely together as defined in the NERC functional model. The Transmission Planner and Planning Coordinator should closely coordinate all work to avoid any unnecessary duplication. Requirement R6 has been included in the standard to ensure that Planning Assessments are complete and coordinated in situations where the Transmission Planner and Planning Coordinator are not the same entity.		
American Transmission Company	B — Unsure about supporting the revised standard	We agree with most of the requirements of revised standard. However, the following list of suggestions and comments are given for consideration. Definitions: We agree with the removal of the "Base Case" definition and the revisions to the other definitions, except as noted above or below. Long Term Planning Horizon definition: We suggest a slight text change of: "Transmission planning period that covers years six through ten. Studies beyond ten years are required to accommodate . . .". Accountability: We suggest that Transmission Service Provider be added because we also suggest that the Transmission Service Provider be the responsible entity for R10. Requirements: We agree with the revisions to the Requirements, except as noted above or below. R1.1 - We agree with the requirement, but would like more description of what to provide in the technical rationale. R2.1 - We agree with the requirement, but suggest this text change, ". . . by the following annual studies . . .". R2.6.1 - We agree with the requirement, but suggest a slight text change of: " . . . short circuit, Generating Unit Stability or System Stability analysis . . .". R2.6.2 - We agree with the requirement, but suggest a slight text change of: " . . . short circuit, Generating Unit Stability or System Stability analysis . . .". R2.7 - We agree with the requirement, as long as it is really required by FERC Order 693 paragraph 1704. R2.7.1 - We agree with the requirement, but suggest a slight text change of: " . . . or Special Protection Systems, . . ." R2.7.1.1 - We disagree with the "include project initiation date" portion of this requirement. The initiation date is often uncertain and subject to change, which may add considerable work to investigate, monitor and update the date. In addition, we do not know why this information is required to assure BES reliability. R2.7.2 - We agree with the requirement, as long as it is really required by FERC Order 693 paragraph 1704. R3.2.2 - We agree with the requirement, but suggest a slight text change of: "For all BES Transmission lines . . .". R3.3.2.1 - We agree with the requirement, but suggest a slight text change of: ". . . shall be allowed in the Planning

Organization	Question 15:	Question 15 Comments:
		Assessment". R3.3.2.2 - We agree with the requirement, but suggest a slight text change of: ". . . within their Facility Ratings and within the time period allowed by the applicable time limited ratings.". R5 - Is the text referring to "known planned outages" and "known long term outages"? What is the distinction that is meant to be made between the two specified types of outages? R5.1 - We agree with the requirement, but suggest a slight text change of: ". . . the response of the applicable portion of the BES". R5.2 - This clarifying requirement should also be included in the short circuit analysis section. R5.3 - We agree with the requirement, but suggest a slight text change of: ". . . capability of all generators that may have a significant adverse effect on the BES." R5.4.3.1 - We agree with the requirement, but suggest a slight text change of: ". . . within their Facility Ratings and within the time period allowed by the applicable time limited ratings.". R8 - We disagree with the requirement, but suggest a text change of: "Each Planning Coordinator shall establish a list of neighboring system and coordinate the distribution of Planning Assessment results among affected entities the listed neighboring systems, coordinating analysis of these results through an open and transparent peer review process." Table 1Planning Events Header: We suggest that the header be repeated on every applicable page to be more reader-friendly. Superscripts: The superscripts do not refer clearly to the respective notes (e.g. there are number notes in the beginning of the table, in the extreme events evaluation requirements section, in extreme event description section, and at the end of the table). Perhaps the notes at the end of the table should have unique numbering to make the superscript references clearer. Shunt device: To avoid the need for future interpretation or clarification, we suggest that the meaning of shunt device be explained or defined somewhere in the standard (e.g. cap bank, inductor bank, SVC, STATCOM, etc.). We need to find out how shunt device outages can (or could in the future) be automatically included in the ACCC routine. We interpret that if each stage of a capacitor bank has a circuit switcher, then the outage would be of the largest cap bank stage. P2.2 (>300 kV), P2.3(>300 kV), P3 (>300 kV), P4 (>300 kV), P5 (>300 kV) - We recognize that the addition of this requirement is an attempt top raise the bar above the existing standards. However, the more stringent performance criteria should only be adopted if there is sufficient evidence to demonstrate the expected reliability risk (i.e. system impact x probability of occurrence) is high enough to warrant the cost of the system modifications that would be needed to meet the criteria. System modifications that involve the installation of line and substation facilities >300 kV will likely take years and cost tens to hundreds of millions to build. It would be helpful to have a reliability risk analysis that justifies the application of

Organization	Question 15:	Question 15 Comments:
		this performance criteria before it is adopted. If the proposed >300 kV performance requirement is retained, then we would want the implementation timeframe to be long enough to allow reasonable time to transition from a system built to the old requirement to a system built for the new requirement. The time needed for planning, design engineering, regulatory approvals, and construction of >300 kV facilities can be very long (e.g. up to 10 or more years). P7 - We disagree with this requirement. Wisconsin statues require giving preference to using existing ROW for new transmission circuits, but this requirement discourages building multiple circuits on common ROW. Should there be a waiver in this standard similar to the TLP-503-MRO-1 standard for lines slightly more than 1 mile based on a review? Extreme Event Evaluation Requirements2 - We agree with the requirement, but perhaps a definition be added for "System Controls", since one exists for "System Protection". 3 - We agree with the requirement, but suggest a slight text change of: "Simulate Normal Clearing unless otherwise specified in the Extreme Event Descriptions." Extreme Event Descriptions2a - We agree with the description, but suggest a slight text change of: "Loss of a structure or tower line with three or more circuits.." 2b & 3b - We agree with the descriptions, but suggest referring to the defined term: "Right-of-Way." 2e, 3.a.i, & 3.a.ii - We agree with the description a, but how large is "large" and how major is "major"? 3.a.v - What is meant by successful cyber attack? Is it a type of cyber attack that is documented to have been successful? 3c - We agree with the description, but suggest a slight text change of: "Other events based upon actual operating experience such as:" Note 4 - We agree with the description, but the acronym FACTS should be explained in the standard or a definition be added for "FACTS". Table 21 - We disagree with this note. We suggest that it be expanded to include the applicable part as Table 1. "The System shall remain stable. In addition, Facility Equipment Ratings shall not be exceeded. Planned System adjustments are allowed, unless precluded in the Requirements, to keep Facilities within the Facility Ratings, if such adjustments are executable within the time duration applicable to the Facility Ratings." 3 - We disagree with this note. We suggest that it be expanded to include the applicable part as Table 1. "Dynamic voltage instability, Cascading outages, and uncontrolled islanding shall not occur." Between 3 & 4 - We disagree with omitting Note 4 of Table 1 from Table 2. We suggest including: "Consequential Load and consequential generation loss is allowed for all events shown." Planning Events Same comments on Header, Superscripts, and Shunt Device as in Table 1.Same comments about stricter requirements for P2.2 (>300 kV), P2.3 (>300 kV), P3 (>300 kV), P4 (>300 kV), P5 (>300 kV) as in Table 1.Same comment

Organization	Question 15:	Question 15 Comments:
		about P7 as in Table 1.Extreme Event Evaluation Requirements Same comment about Requirement 2 and 3 as in Table 1. 3 - We agree with the requirement, but suggest a slight text change of: "Simulate Normal Clearing unless otherwise specified in the Extreme Event Descriptions." Notes5 - We disagree with limiting this requirement to just Category P1 category. We suggest that the synchronism requirement be applied to more categories.

Response: The SDT believes that a review of system conditions beyond the 10-year horizon is warranted. FERC Order 693 requires that the planning horizon take into account the lead times for siting and permitting of new long-distance Transmission lines and other long lead time solutions. The SDT has received industry comments regarding the need to exceed a 10-year horizon to account for longer lead time projects. Establishing planning horizons that are shorter than Transmission lead times may create gaps where the identification of a reliability need to which Transmission may be the best solution occurs too late to avert the identified reliability violation. Further, Operating Procedures or alternative short-term capital projects may be needed to limit the impact of the Planning Event until the planned Facilities can be completed. This information needs to be included in the Assessment.

In response to industry comments, the SDT has removed Requirements R9-R14 thus eliminating any need to add the Transmission Service Provider.

R1.1 - The SDT agrees and has removed the need for documentation of the technical rationale for modification of any data.

R2.1 - The SDT believes that the existing language is appropriate and there needs to be a distinction between current and past studies that would allow both to support compliance with the requirement.

R2.6.1 & R2.6.2 - Based on comments from others, the SDT has removed the requirements for separate Generating Unit Stability analysis and System Stability analysis.

R2.7 (now R2.6) – The SDT believes that it is.

R2.7.1 (now R2.6.1) - The SDT agrees with the proposed change.

Installation or modification of Protection Systems or Special Protection Systems.

R2.7.1.1 (now R2.6.2) - The SDT believes that a project initiation date is an effective measure to track a functional entity's planning and engineering activities and their efforts to provide and maintain a reliable BES.

R2.7.2 – Requirement R2.7.2 has been deleted.

R3.2.2 - The Purpose section of the Standard states that this Standard is to develop requirements for the Bulk Electric System, BES. No change required.

R3.3.2.1 – Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.8 which includes the term 'Planning Assessment'.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

Organization	Question 15:	Question 15 Comments:

R3.3.2.2 - Based on your comment, the SDT has addressed the applicable time-limited rating in what was Header note 'a' for Steady State Only in Table 1 - Steady State & Stability Performance. Requirement R3.3.2.2 has been deleted in favor of Header note 'e' in the revised Table. Please note that the two tables in the second draft have been reduced to one table in the third draft.

Header note 'e' - For all Planning Events, planned System adjustments such as Transmission configuration changes and redispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

R5 - The SDT agrees and has moved this concept within Requirement R1 (see Requirement R1.1.1) so that it is applicable to all Planning Assessments. Further, both Requirements R3 and R5 (now R4) have been revised to make reference to Requirement R1.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources,~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. ~~The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to cContingencies in Table 1 – Steady State Performance.~~ The studies shall be based on computer simulations using models utilizing data provided in Requirement R1.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~

R5.1 - Most of the industry did not have difficulty understanding that the analysis is limited to the Transmission Planner's or Planning Coordinator's portion of the BES. Therefore, the SDT is not persuaded by your comment to add extra wording.

R5.2 - The SDT has moved the short circuit analysis from Requirement R4 to Requirement R2.7 and R2 already references BES.

R5.3 - The SDT disagrees with the suggested change due to the additional studies that would be required to determine which generators would have an adverse impact.

The SDT has deleted R5.4.3.1.

The SDT has clarified this issue in Requirement R8 (now R7).

R7 Each Planning Coordinator shall coordinate the distribution of Planning Assessment results among ~~neighboring systems~~ adjacent Planning Coordinators and any functional entity who has indicated a reliability need, coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890.

Organization	Question 15:	Question 15 Comments:
Header - The SDT also feels that the Tables need to be as clear and concise as possible. To that end, the next version will combine Tables 1 and 2 into one table with a revised format. The Planning Events are shown on one page so repeating the headings will not be needed. Superscripts - All the notes from both tables have been combined and listed numerically. Shunt device - The SDT believes that shunt device is commonly used in the electric utility industry and does not require any further explanation. The SDT recommends contacting the software manufacturer for additional information about the ACCC routine. The SDT believes that the cap bank outage would be based on what elements would need to trip in order to clear the simulated fault condition. P2 - The SDT is attempting to raise the bar by developing a standard that appropriately supports BES reliability and has industry consensus. The majority of the SDT believes that 300 kV is an appropriate cutoff and that Transmission Systems above this level represent backbone Systems and are part of regional "grids". The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations and has provided for flexibility in Corrective Action Plans. The Implementation Plan will be addressed in the next posting of the standard. P7 - The SDT is cognizant of the concerns surrounding the construction of new Transmission lines, including the desire by many to fully utilize existing Right-of-Ways. In its consideration of Footnote 12 (exclusion for common structures less than 1 mile), the SDT considered the impact that this requirement could have on construction of new Facilities. However, after deliberations, the SDT believes that the 1 mile exclusion should be maintained for the reliability of the BES and that individual exceptions can be addressed within the NERC process. Extreme Events 2 - The SDT agrees that "Protection System" is defined in the Glossary of Terms Used In Reliability Standards. However, the SDT believes that this issue should be more properly addressed by the NERC SPCTF drafting team. 3 - The SDT has previously included "For all Extreme Events evaluated" at the beginning of the Evaluation Requirements for Extreme Events. No change required. 2a - The SDT believes that the Extreme Events #2.a. is already sufficient. 2b - The SDT will use the defined term of "Right-of-Way" as suggested (see 2b steady state and 2 g Stability). 2e et al - The SDT suggests that the terms "large", "major", and "successful" be defined between the Transmission Planner and Planning Coordinator. 3a - The SDT believes that the wording (was 3c) is already sufficient. No change required. Note 4 - The SDT believes that "FACTS" is commonly used in the electric utility industry and does not require any further explanation. Table 21 - The SDT has reviewed your comment and feels that your request to add "Facility Equipment Ratings shall not be exceeded. Planned System adjustments are allowed, unless precluded in the Requirements, to keep Facilities within the Facility Ratings, if such adjustments are executable within the time duration applicable to the Facility Ratings." apply to Stability is not appropriate. For the purposes of this standard, Facility Equipment Ratings refer to steady state calculated values and planned System adjustments refer to the time frame associated with returning the thermal flow within the applicable steady state Facility Rating. 3 - The SDT agrees with your comment and has made that change in Header note 'a' in the next version. Also, the next version will combine Tables 1 and 2		

Organization	Question 15:	Question 15 Comments:
into one table with a revised format. 3 & 4 - The SDT has reformatted and combined the two Tables into a single Table for the next draft. 3 – The SDT has already included "For all Extreme Events Evaluated" at the beginning of the Evaluation Requirements for Extreme Events. 5 - The SDT also feels that the synchronism requirement should apply to more than just P1 Category but under certain conditions and has adjusted the notes accordingly. **Footnote 1.a.ii -** For all other Planning Events: No generating unit or units totaling more than the Contingency ~~r~~Reserve of the Balancing Authority (or Reserve Sharing Group if applicable) shall be allowed to pull out of synchronism. Generators that pull out of synchronism must have out-of-step protection or some other means to trip the generator for this condition and the resulting apparent impedance swings must not pass through relay characteristics that would result in the tripping of any Transmission System elements other than the generating unit and its direct connection Facilities.		
Duke Energy	B — Unsure about supporting the revised standard	While we generally support the revised standard, we are unsure of the total cost impact, and whether the additional costs are justified by increased reliability. 1) Load Modeling is a significant open issue. The models for dynamic studies have yet to be developed and the data is not in hand. This standard should allow for the use of the best available information. 2) Category P6 is the loss of a system element, following system adjustments, followed by the loss of another element. The table columns for this category say that interruption of firm transmission service and non-consequential load loss is allowed. The table, however, is not clear whether the interruption of firm service and non-consequential load loss is allowed as part of the system adjustment (between the outages) or whether it is only allowed after the second outage. It was stated in the NERC TPL SDT WebEx that the interruption is not allowed as part of the system adjustment. This would be a dramatic change from the existing standard and would result in the unintended consequence of significantly reducing transfer capability of interfaces to a fraction of their currently reported capability. This would in effect be imposing an n-2 criteria for offering firm transmission service. Duke Energy does not believe this would be an acceptable situation for the users, owners and operators of the bulk power system. 3) The statement in R2.7 "Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities," implies that there are performance requirements for sensitivity studies. Recommend rewording to clarify that there are no performance requirements for sensitivity studies. 4) Recommend rewording R3.3.2.1 as follows: "The single highest consequential load loss and its expected duration following a single contingency shall be documented in the Planning Assessment." 5) In R5.3 the statement, ?and identify how the generators are treated in the simulation,? should be deleted. The word "treated" is vague and typically specific equipment modeling is not identified in studies. The implementation schedule should also take into account the Standard to develop and provide this data is not approved. Since this data is not yet available, please revise the statement as follows: ?Studies shall use the best available information to consider the voltage

Organization	Question 15:	Question 15 Comments:
		ride through capability of all generators." 6) In Table 1, Category P2 Event 1 needs to be revised to recognize the impact of this event on Bulk Electric System reliability for events on the system that are > 300 kV vs. events on the system that are <= 300 kV. P2.1 should not allow for interruption of firm transmission service or loss of non-consequential load for > 300kV; however, it should allow for interruption of firm transmission service or loss of non-consequential load for <= 300 kV. The requirement as currently written would require expenditures for the <= 300 KV system where such an event has minimal impact on Bulk Electric System reliability. In addition, the likelihood of events needs to be considered as requirements are developed. A review of Duke Energy Carolinas data shows that the likelihood of a P2.1 event on Duke's 100 kV system is an order of magnitude less than for a P1 event on the same 100 kV system. This is another indicator that the requirement as written would result in the need for expenditures that provide minimal value to enhancing the reliability of the Bulk Electric System.

Response: The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors involved here and has taken them into consideration in its deliberations in the development of this draft.

1. The SDT agrees and believes that industry guidance is needed to capture the appropriate dynamic behavior of loads. In response to comments from you and others in the industry, the SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. Requirement R2.4.1 has been modified to clarify expectations regarding Load modeling for dynamics studies.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations.

R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable.

2. The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in the Revision 3 of the Standard provides clarification.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

3. The SDT has modified the language dealing with the sensitivities in Requirement R2.7 (now R2.6) and added the phrase "run in accordance with Requirements R2.1.3 and R2.4.3." However, the performance requirements for sensitivity studies are the same as the performance requirements for the base study. The difference is that a Corrective Action Plan is required when performance requirements are not met in the base study. A Corrective Action Plan is not

Organization	Question 15:	Question 15 Comments:
necessarily required when the performance requirements are not met for a sensitivity study. **R2.6** For Planning Events shown in Table 1~~ – Steady State Performance and Table 2 – Stability Performance~~, when the analysis indicates an inability of the System to meet the performance requirements in ~~the t~~Table~~s~~ 1, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall: 4. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been removed from the draft. **R2.8** The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1. 5. The SDT has revised Requirement R5.3 (now R4.3.2) to provide clarification in this area. **R4.3.2** ~~Studies shall consider~~ Simulate generator performance under anticipated conditions including how the voltage ride through capability ~~of all generators and identify how the generators are treated~~ is analyzed~~in the simulation~~ 6. The SDT feels that for this event (explained in detail in footnote 8 of draft 3 of this Standard) interruption of neither firm nor Non-Consequential Load should be allowed for any BES voltage level, i.e., above or below 300 kV. This is consistent with FERC Order 693 that does not allow dropping of Non-Consequential firm Load following any single Contingency.		
Florida Reliability Coordinating Council, inc	C — Definitely do not support the revised standard	The SDT should consider and allow, for all planning events, , loss of Non-Consequential load as an interim measure for a period of up to 5 years in the situation where system load growth has caused post-contingency action plans to not effectively bring Facilities within normal operating limits due to unexpected or unforeseen regulatory requirements, equipment capability* and/or the installation of large industrial/commercial customers. *Equipment Capability is added to address unforeseen industry changes in the methodology used to calculating the rating of equipment.
Response: Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an Interruptible Load contract arrangement.		
Central Maine Power	B —Unsure about supporting the	Aside from the comments to the prior questions, there are several issues of concern that prevent us from supporting the present draft of the revised standard. We offer the following constructive comments in an effort to support the worthwhile effort that is being pursued so that we can reach a point of satisfaction that we could vote to support the revised standard.

Organization	Question 15:	Question 15 Comments:
Company	revised standard	Our concerns are listed in a rough order of priority. a. This standard as drafted does not allow exceptions for small parts of the system as long as interconnected system reliability is maintained, which is allowed in the existing TPL standards in footnotes b) and c) in Table 1. Unless such exceptions are allowed significant transfer restrictions or large reinforcements must be made. The applicable TPL footnotes are: Existing TPL footnote b) Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers. Existing TPL footnote c) Depending on system design and expected system impacts, the controlled interruption of electric supply to customers (load shedding), the planned removal from service of certain generators, and/or the curtailment of contracted Firm (nonrecallable reserved) electric power Transfers may be necessary to maintain the overall reliability of the interconnected transmission systems. b. This standard does no address base conditions. Without defining base conditions the initial status of generation dispatch and transfers across the system is ill defined. Therefore the contingency analysis doesn't have a predictable basis for a consistent and repeatable study. c. The reference to Special Protection Systems is completely permissive. Although there are good applications for Special Protection Systems, their use must be constrained to have a reliable system and to promote construction of needed infrastructure. d. This standard does not provide flexibility to shed load, which restricts the ability to control post contingency response for low impact events. This may result in advancing need for upgrades in response to low impact events. This may result in advancing need for upgrades in response to low impact events. This is in conflict with FERC's directive to have the Transmission Provider waiting for market response to transmission needs and having the Transmission Provider provide a role to back stop the market. e. Definition of the Long-Term Planning Horizion. The planning horizion, for assessment purposes should be limited to 10 years. Such an assessment should be sufficient to identify requirements that may take an extended time to implement. f. Definition of Planning Coordinator is part of the NERC Functional Model, Remove from the standard. g. Put headings on each section to identify the requirements of the section. h. With respect to R2.2 - Delete "current" from the phrase "current System Peak Load Study" and replace "study" with "assessment." i. Remove R2.2.1, the requirement to extend the assessment beyond 10 years. What does the length of the project have to do with the assessment? If it takes 15 years to build something, why does this require a review of year 15? What is the

Organization	Question 15:	Question 15 Comments:
		purpose of this assessment? j. R3.3.2 requires clarification - This standard needs to permit discretion regarding the single contingencies that need to be tested, similar to R3.3.3 and R3.4. It is completely unnecessary to test all events. For example, contingencies may be limited to relevant disturbances that are contained within or directly impact the studied system. k. With respect to R3.2.1 - Clarify whether the intent of the standard is to address station service minimum voltage limitation, maximum leading VAR absorption capability or both at steady state. l. Remove R3.2.2 - Relay loadibility is addressed in the PRC-023 Standard. m. With respect to R3.3.2.1 - Recommend the removal of the requirement to assess the expected duration of Consequential Load loss. It's not considered anywhere else in the standard. n. With respect to R3.3.3 - The paragraph refers to Table 1 Contingencies P3 through P7; this should be explicitly stated. Rationale for inclusion of testing should not be required; should only need to explain why certain Contingencies were not tested. This discretion should be applicable to all contingencies. o. With respect to section R5 - The concept of planned and long-term outages should apply to the general Planning Assessment, or not at all. It should not be specific to the Stability Assessment. p. The provisions of Section R5.3 should have a corresponding MOD standard apply a requirement to provide information regarding all direct and indirect protective and control actions that could result in the inadvertent trip of the generator. Such a provision should include "other equipment (e.g. HVDC, SVC's, Statcoms)", and identify how those devices are treated in the simulation. q. Planned outages should be addressed in the operating horizon unless otherwise defined in the planning horizon. r. Recommend allowing the same non-consequential interruption for >300kV as for <300kV. Distinctions and acceptability should be based on consequence, not voltage class. s. What is a "current" study?
ISO New England Inc.	B — Unsure about supporting the revised standard	Aside from the comments to the prior questions, there are several issues of concern that prevent us from supporting the present draft of the revised standard. Recommend allowing the same non-consequential interruption for >300kV as for <300kV. Distinctions and acceptability should be based on consequence, not voltage class. s. What is a "current" study?

Response: A. Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an interruptible Load contract arrangement.

B. The SDT has modified Requirement R1 to include additional details on what should be modeled in the cases. However, the SDT intentionally provides flexibility for the Transmission Planner/Planning Coordinator to decide which "base case" to use since initial conditions for a System will vary from region to region and will need to be established on a local level, not via a national standard. The required studies and sensitivity analysis ensures that sufficient study is performed to cover an appropriate range of System conditions.

C. The SDT does not believe that it would be appropriate to attempt to specify limitations to the use of Special Protection Systems in this standard. The proposed TPL-001-1 and existing standards provide adequate guidance to the industry on application of Special Protection Systems.

Organization	Question 15:	Question 15 Comments:

D. The SDT has made clarifications regarding Firm Transmission Service and Non-Consequential Load Loss. Footnote # 10 has been added to the end of Table 1. The standard does not preclude the possibility of obtaining contractually interruptible load. It is the general opinion of the SDT that dropping of Non-Consequential Load should not be allowed for the Planning Events involving only one element as described in Table 1 of the proposed Standard, and to meet the intent of FERC Order 693. Further, this Standard is proposed to "raise the bar" to improve System reliability, which would require responses (Corrective Action Plans) to address those so-called low-impact events that may have been overlooked or ignored with the existing Standard TPL-002-0.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

E. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted. FERC Order 693 requires that the planning horizon take into account the lead times for siting and permitting of new long-distance Transmission lines and other long lead time solutions. The SDT has received industry comments regarding the need to exceed a 10-year horizon to account for longer lead time projects. Establishing planning horizons that are shorter than Transmission lead times may create gaps where the identification of a reliability need to which Transmission may be the best solution occurs too late to avert the identified reliability violation. Further, Operating Procedures or alternative short-term capital projects may be needed to limit the impact of the Planning Event until the planned facilities can be completed. This information needs to be included in the Assessment.

F. The definition for Planning Coordinator was deleted because the term has already been defined and added to the NERC Glossary by another SDT.

G. The SDT also feels that the Tables need to be as clear and concise as possible. To that end, the next version will combine Tables 1 and 2 into one table with a revised format.

H. The SDT believes that the existing language is appropriate.

I. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted under some circumstances. For example, if it takes 15 years to build a Transmission line, then the need for that line would have to be determined 15 years ahead of the in-service date. Therefore, Requirement R2.2.1 requires you to perform an Assessment on year 15 if it takes you 15 years to build a line.

J. The SDT has removed Requirement R3.3.2 and replaced it with additional language in Requirement R3.1. The SDT does agree with your interpretation that it does not require evaluation of all single Contingencies. The SDT specifically states in **R**equirement R3.4 that those Contingencies that are expected to produce the more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe results.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1~~ – Steady State Performance.~~ based on the lists created in Requirement R3.5.

K. The SDT has not limited the purpose of this requirement to either minimum acceptable station service voltages or maximum Mvar absorption. The SDT believes that the purpose of Requirement R3.2.1 is to determine if generators could continue to operate or if they would trip off following the Contingency.

Organization	Question 15:	Question 15 Comments:

L. The SDT believes that relay load limits or loadability need to be considered in the Contingency analyses. The studies should determine if Transmission line loadings could reach the relay loadability level, which may add to the existing Contingency and perhaps, result in an unbounded cascading event.

M. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R 2.9 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been deleted in favor of new Requirement R2.9.

R2.9 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

N. The SDT has re-written Requirement R3.3 (now Requirement R3.5) to address your initial concern. Although the language and format of the proposed Standard have been revised from earlier versions, the SDT continues to believe that the Transmission Planners should evaluate the System performance for the events that are expected to produce the more severe System impacts, including both single and multi-Contingency events. The wording of new Requirement R3.5 (the old Requirement R3.3.3) now requires a listing of the Contingencies to be evaluated, the rationale for their selection and why the remaining Contingencies would be expected to produce less severe results. This will provide a complete evaluation of the potential Contingencies to be studied – those selected and those excluded.

R3.5 Those Planning Event Contingencies in Table 1 ~~– Steady State Performance not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.

O. The SDT agrees and has moved this concept within Requirement R1 (see Requirement R1.1.1) so that it is applicable to all planning Assessments. Further, both Requirement R3 and Requirement R5 have been revised to make reference to Requirement R1.

R1.1.1 Planned outages of generation and Transmission Facilities, if specifically known.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. ~~The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to c~~Contingencies in Table 1 ~~– Steady State Performance.~~ The studies shall be based on computer simulations using models utilizing data provided in Requirement R1.

R5 For the Stability portion of the Planning Assessment, as described in Requirement R2.4 ~~and Requirement R2.5~~, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table ~~2~~1 ~~– Stability Performance~~. The studies shall be based on computer simulations using models utilizing data provided in Requirement R1. ~~The studies shall be based on computer simulations using models utilizing data provided in Requirements R9 through R14, the MOD-010 and MOD-012 standards, and other data sources, to include known planned and long term outages of Transmission or generation equipment. The studies shall cover both System Stability and Generating Unit Stability. The following requirements apply to both System Stability and Generating Unit Stability studies unless otherwise noted.~~

P. Requirement R5.3 has been modified to address simulation of how generators perform under conditions being studied. The current MOD standards that address steady-state and dynamic simulation data requirements do not explicitly require the Generator Operators to provide voltage ride-through capability.

Organization	Question 15:	Question 15 Comments:
These standards are set to be addressed by Project 2010-04 within NERC's Standards Development Work Plan. It is expected that the Transmission Planner would contact Generator Operators applicable to their System to obtain such data. If the data is not provided, it would be expected that a Transmission Planner state its assumption on the Vmin used for a generator terminal voltage for assessing ride-through capability. It's likely such information could be obtained through generator manufacturers. The "Other equipment" is addressed in the revised R5.4. Q. The SDT agrees and therefore has changed R1.1.1 to state "if specifically known." R. FERC order 693 (see paragraphs 342, 1792, 1794) suggests that Non-Consequential Load loss for single Contingencies is unacceptable. Note from paragraph 1792 of order 693: "We view these arguments as based largely on the matter of economics, not reliability, with the underlying premise that it is not economically feasible to invest in the bulk electric system to the point that it can continue service to all firm load customers under some specific N-1 scenarios." The fact that the table allows Load loss for some "lower probability" N-1 events (some P2 events) for any Transmission voltage is recognition by the SDT that probability impacts both costs and practicality. S. The SDT believes that a current study is a study that has been completed for the latest Assessment, as opposed to a past study that may have been completed up to five years ago.		
NSTAR Electric	B — Unsure about supporting the revised standard	Aside from the comments to the prior questions, listed below are several others issues: 1. This standard does not address base conditions regarding generation dispatch and transfers across the system. Initial condition guidelines would be very important to establishing consistent application of the performance standards. 2. This standard should allow exceptions for loss of small parts of the system as long as reliability is maintained on the interconnected BES. There is such an allowance in the existing TPL standards in Table 1, footnotes b) and c). 3. The reference to Special Protection Systems is too permissive. The use of Special Protection Systems and their inherent complexity should be restricted to ensure a reliable system and to promote construction of needed infrastructure. 4. The Long-Term Planning Horizon should be limited to 10 years, a sufficient timeframe to identify requirements that may take an extended time to implement. 5. Definition of Planning Coordinator is part of the NERC Functional Model. It should be removed from the TPL standard. 6. Put headings on each section to identify the requirements of the section. 7. With respect to R2.2, delete "current" from the phrase "current System Peak Load Study" and replace "Study" with "Assessment." 8. R3.3.2 should be changed to permit discretion regarding the single contingencies that need to be tested, similar to R3.3.3 and R3.4. It is unnecessary to test all possible events. 9. R3.2.1 should be clarified as to whether the intent of the standard is to address station service minimum voltage

Organization	Question 15:	Question 15 Comments:
		limitation, maximum leading VAR absorption capability or both. 10. Remove R3.2.2. Relay loadibility is addressed in the PRC-023 Standard. 11. In R3.3.2.1, remove the requirement to assess the expected duration of Consequential Load loss. This requirement is unnecessary and not considered anywhere else in the standard. 12. With respect to R3.3.3, the paragraph refers to Table 1 Contingencies P3 through P7; this should be explicitly stated. Also, the rationale for inclusion of testing should not be required. It only makes sense to explain why certain Contingencies were not tested. This discretion should be applicable to all contingencies in all sections of the standard.

Response: 1. The SDT has modified Requirement R1 to include additional details on what should be modeled in the cases. However, the SDT intentionally provides flexibility for the Transmission Planner/Planning Coordinator to decide which "base case" to use since initial conditions for a System will vary from region to region and will need to be established on a local level, not via a national standard. The required studies and sensitivity analysis ensures that sufficient study is performed to cover an appropriate range of System conditions.

2. Some commenters expressed concern with the inability to shed Non-Consequential Load in response to a single Contingency event. It was indicated that some stakeholders rely on an SPS to drop local area network Load in response to some single Contingency events and that these System designs are permissible under the presently approved TPL-002-0 standard. FERC in Order 693 was clear in paragraph 1794 that that interruption of Non-Consequential Load is not permitted for single Contingency events. This position was vetted in draft 1 of TPL-001-1 and most stakeholders and the SDT support this position. The use of an SPS design would be permitted for a single Contingency event if the SPS design interrupts service to customers involved in an Interruptible Load contract arrangement. As an alternative, an entity could seek an Entity Variance for the situation described through their Regional Entity organization. In paragraph 1794 FERC clarified that "…an entity may seek a regional difference to the Reliability Standard from the ERO for case-specific circumstances". The process described by FERC as a regional difference is described in detail in the "NERC Standards Development Procedure" document under the subsection titled "Variances to NERC Reliability Standards".

3. The SDT does not believe that it would be appropriate to attempt to specify limitations to the use of Special Protection Systems in this standard. The proposed TPL-001-1 and existing standards provide adequate guidance to the industry on application of Special Protection Systems.

4. The SDT believes that a review of System conditions beyond the 10-year horizon is warranted. FERC Order 693 requires that the planning horizon take into account the lead times for siting and permitting of new long-distance Transmission lines and other long lead time solutions. The SDT has received industry comments regarding the need to exceed a 10-year horizon to account for longer lead time projects. Establishing planning horizons that are shorter than Transmission lead times may create gaps where the identification of a reliability need to which Transmission may be the best solution occurs too late to avert the identified reliability violation. Further, Operating Procedures or alternative short-term capital projects may be needed to limit the impact of the Planning Event until the planned Facilities can be completed. This information needs to be included in the Assessment.

5. The definition for Planning Coordinator was deleted because the term has already been defined and added to the NERC Glossary by another SDT.

6. The SDT has considered this action but NERC's legal staff advised against using headings in the body of standards.

<table>
<tr><th>Organization</th><th>Question 15:</th><th>Question 15 Comments:</th></tr>
<tr><td colspan="3">7. The SDT believes that the existing language is appropriate.

8. The SDT has removed the Requirement R3.3.2 and replaced it with additional language in Requirement R3.1. The SDT does agree with your interpretation that it does not require evaluation of all single Contingencies. The SDT specifically states in Requirement R3.4 that those Contingencies that are expected to produce the more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe results.

R3.1 Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 ~~– Steady State Performance.~~ based on the lists created in Requirement R3.4.

9. The SDT has not limited the purpose of this requirement to either minimum acceptable station service voltages or maximum Mvar absorption. The SDT believes that the purpose of Requirement R3.2.1 (now R3.3.2) is to determine if generators could continue to operate or if they would trip off following the contingency.

10. The SDT believes that relay load limits or loadability need to be considered in the Contingency analyses. The studies should determine if Transmission line loadings could reach the relay loadability limits, which may add to the existing Contingency and perhaps, result in an unbounded cascading event.

11. To meet industry concern as well as FERC Order 693, the SDT has added Requirement R2.8 to identify the event causing the single largest Consequential Load Loss Demand and its value and eliminate the reporting of the expected duration. Requirement R3.3.2.1 has been removed from the draft.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

12. Although the implied assumption that the more severe impacts would be identified in the P3 through P7 Contingencies, there may be exceptions and the SDT does not believe it necessary to modify the language in this regard. The wording of new Requirement R3.~~5~~ 4 (the old Requirement R3.3.3) now requires a listing of the Contingencies to be evaluated, the rationale for their selection and why the remaining Contingencies would be expected to produce less severe results. This will provide a complete evaluation of the potential Contingencies to be studied – those selected and those excluded.

R3.4 Those Planning Event Contingencies in Table 1 ~~– Steady State Performance not covered in Requirement R3.3.2~~ that are expected to produce more severe System impacts shall be identified~~,~~ and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created~~,~~. ~~and t~~The rationale for the Contingencies selected for evaluation shall be available as supporting information and shall ~~includ~~include~~e~~ an explanation of why the remaining Contingencies would produce less severe System results.</td></tr>
<tr><td>SERC Reliability Review Subcommittee and Planning Standards Subcommittee</td><td></td><td>C. Definitely do not support the revised standard. A majority of SERC technical experts do not support the revised standard. The primary concern is that the need for additional requirements for planning 300kV systems and above has not been demonstrated. We do not believe that a sufficient case for ?raising the bar? has been provided and that this requirement can have a huge impact on utilities and ratepayers.

R2.1.3 and R2.4.3 requirements are very prescriptive. Many examples of sensitivities are already inherent in the existing requirements. Some sensitivity studies are in effect adding an additional level of contingency (N-2 or N-3). Sensitivity studies of load variation are already inherent in the fact that several different study years and conditions are already being</td></tr>
</table>

Organization	Question 15:	Question 15 Comments:
		required. Outages of reactive sources and generation should already be included in studies of multiple contingencies. The process of planning new generation (system impact studies) will include studies of the future with and without the proposed new equipment. The TP and PC can better select the most appropriate sensitivities for their system. We recommend that engineering judgment continue to be recognized as a vital component of planning. Category P6 is the loss of a system element, followed by system adjustments, followed by the loss of another element. The table columns for this category say that interruption of firm transmission service is allowed. The table, however, is not clear whether the interruption of firm service is allowed as part of the system adjustment (between the outages) or whether it is only allowed after the second outage. It was stated in the NERC TPL SDT WebEx (August 26, 2008) that the interruption is not allowed as part of the system adjustment. This would be a dramatic change from the existing standard and would result in the unintended consequence of significantly reducing transmission system capability to accommodate firm transmission service including reduction of transfer capability of interfaces to a fraction of their currently reported capability. This would in effect be imposing an n-2 criteria for offering firm transmission service. This would not be an acceptable situation for the users, owners and operators of the bulk power system. Additional Comments: There is concern with load modeling requirements (use of word ?appropriately? in R2.4.1). Does this requirement mandate the use of specific load models for each bus, or would an aggregate load model which represents the system as a whole be sufficient? Does the use of the PSS/E CONL function satisfy the requirements for a load model? There is a concern that R3.3.2.1 is burdensome regarding the need to keep track of the quantity of consequential load loss and expected duration. Who is collecting this information and why is it needed? It appears that this is a local regulatory issue, not a reliability issue. There is a concern with R5.6.1 with the requirement to perform simulations on 20 MW generators (to be consistent with the Registration Criteria). We recommend a 75 MW generator cutoff for required simulations.

Response: The SDT is attempting to raise the bar by developing a standard that appropriately supports BES reliability and has industry consensus. The majority of the SDT believes that 300 kV is an appropriate cutoff and that Transmission Systems above this level represent backbone Systems and are part of regional "grids". The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations and has provided for flexibility in corrective action plans. FERC has noted in their orders that many of the concerns about raising the bar show more concern about economics than reliability (examples, Order 890, paragraph 423; Order 693, paragraph 1792, etc.).

The SDT agrees and have clarified the language to allow the Transmission Planner and Planning Coordinator to chose the sensitivities (Requirements R2.1.3 & R2.4.3)

R2.1.3 For each of the studies described in Requirements R2.1.1 and ~~Requirement~~ R2.1.2, sensitivity case(s) that are intended to stress the System with ~~sensitivities~~ variations ~~that reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

<table>
<tr><th>Organization</th><th>Question 15:</th><th>Question 15 Comments:</th></tr>
<tr><td colspan="3">

R2.4.3 For each of the studies described in Requirements R2.4.1 and ~~Requirement~~ R2.4.2, sensitivity case(s) that are intended to stress the System with variations ~~to reflect~~ in one or more of the following conditions not already included in the studies shall be ~~run and documentation of the technical rationale for why each of the conditions was or was not selected shall be supplied~~ included in the Assessment:

The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in the Revision 3 of the Standard provides clarification.

Footnote #10 – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.

The SDT does not believe that specific Load models for each bus are necessary. An aggregate Load model which represents the System behavior as a whole may be used. Requirement R2.4.1 has been revised. The SDT does not believe that the use of PSS/E Activity CONL by itself provides the appropriate representation for dynamic Loads. For example, the SDT believes that using PSS/E Activity CONL is not sufficiently robust to appropriately model summer peak Loads with high concentrations of induction motors during for low voltage/motor stall conditions. A dynamic Load model such as CLOD, in conjunction with Activity CONL to model the non-induction motor load would be required to more accurately assess the system for FIDVR - Fault Induced Delayed Voltage Recovery.

R2.4.1 System peak Load for one of the five years. For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads. An aggregate system Load model which represents the overall dynamic behavior of the Load is acceptable.

To meet industry concern as well as FERC Order 693, the SDT has deleted Requirement R3.3.2.1 and replaced it with Requirement R 2.8. The SDT believes that quantifying the single largest Consequential Load Loss and identifying the event causing it provides a useful metric for system performance and reliability.

R2.8 The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1.

The requirement for study has been changed to 20 MW for a single generator or for an aggregate of generators. This language is now in Requirement R2.5.2.

R2.5.2 For steady state, short circuit, ~~Generating Plant Stability,~~ or ~~System~~ Stability analysis: the ~~study~~ present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include:

</td></tr>
<tr><td>Oncor Electric Delivery</td><td>B — Unsure about supporting the revised</td><td>Initially performing outstanding tasks as well as annual maintenance of documentation and regular updates would require extreme significant resources both personal and financial. Transmission Planning to this level requires high level subject matter experts with both specific transmission system knowledge as well as overall industry experience. Considerable expense would also be required to train personal and track activities. The procurement documents necessary to interface</td></tr>
</table>

Organization	Question 15:	Question 15 Comments:
	standard	with consultants in this area where "in house" expertise is not available would also be required. Time would also be spent on evaluating new software and analysis tools such as EPRI dynamic models. A phased in approach would be taken to complete the tasks while still performing essential Oncor and ERCOT related activities associated with System Planning.
Response: The SDT has received many comments regarding the increased planning requirements to meet the proposed standard. However, the SDT believes that the requirements for sensitivity studies must remain to satisfy FERC Order 693. FERC has stated that the sensitivity studies would be used to document the selection of critical System conditions and study years used in assessing System conditions (see paragraph 1704) and that System conditions are as important as Contingencies in evaluating the performance of present and future Systems (paragraph 1705). The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors involved and has considered them in its deliberations. The SDT is developing the Implementation Plan and will include it in the next draft of the standard		
FirstEnergy Corp.	A — Generally support the revised standard	1) For this standard, "Protection System" failure should be limited to only relay event failures. 2) R1 ? As stated in our response to Question 5, FE does not support the modeling requirements within the TPL standard and suggest that the SDT remove these requirements. This standard should be viewed on a premise that a valid and appropriate system model exist so that the fundamental focus of the standard is as stated in its purpose statement "Establish Transmission System planning performance requirements... to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions." If R1 remains, the phrase "and other data sources" should be removed. 3) R1.1 ? this requirement requires the documentation of ANY data modification. Do you really mean ANY? How much detail is needed in the documentation? Is a line by line comparison of all data values before/after needed or is a general overview discussion sufficient? For instance, FE replaces its system model as shown in the MMWG representation with a more detailed system representation model when performing planning studies. This can included many differences from the MMWG system equivalent. How much documentation is needed in this situation? 4) R2.6 ? This is not a requirement and should be removed and shown as explanatory text (footnote). 5) R3 - Requirement R3.1 is redundant to statements in the text of R3 and R3.3 and R3.4. We suggest that R3.1 be removed. It is suggested that R3.4 be indented and become a R3.3 sub-requirement. R3.5 would be better placed ahead of R3.3 along with the existing R3.2.
Response: 1. The SDT believes that these protection issues will be further clarified by the NERC SPCTF drafting team. The spirit of the TPL standard will remain that Load loss must not be planned for any single failure. 2. The SDT has removed Requirements R9-R14 and enhanced Requirement R1 to more clearly specify the modeling information needed to support accurate Planning Assessments. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models for performing the studies needed to complete their Planning		

Organization	Question 15:	Question 15 Comments:
Assessment. The models shall use data consistent with the data provided in accordance with ~~Requirements R9 through R14,~~ the MOD-010 and MOD-012 standards~~,~~ and other data sources, ~~.~~ and shall simulate projected System conditions including requirements of regulatory authorities and other legal obligations. 3. The SDT agrees and has removed the need for documentation of the technical rationale for modification of any data. 4. The SDT disagrees and believes that the format and language of Requirement R2.6 (now R2.5) and its new sub-requirements are appropriate. 5. The SDT has modified the language of Requirement R3.1 and deleted Requirement R3.3 to eliminate the redundancy. **R3.1** Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 ~~– Steady State Performance.~~ based on the lists created in Requirement R3.5.		
Orlando Utilities Commission	C — Definitely do not support the revised standard	This standard is a definite improvement over the current set of standards. The majority of my comments are on details rather then the overall concept. My single biggest concern is the handling of n-1-1. This represents a significant expense to transmission customers and serious restriction on making firm transmission available, but due to the low probability of these events it would represent little if any practical improvement in customer reliability or grid security.
Response: Please see footnote #10 with regard to N-1-1. The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
Entergy Services, Inc.	C — Definitely do not support the revised standard	No cost-benefit studies have been completed to justify the significant investment and no detailed analysis of the expected reliability impact has been conducted for the Eastern Interconnection. Some research suggests that infrastructure expansion will reduce the number of large BES events, but that each event would impact larger areas with longer restoration times. http://eceserv0.ece.wisc.edu/~dobson/PAPERS/complexsystemsresearch.html Additionally, there is a fatal disconnect between the enhanced reliability standard and the FERC's current standard for selling firm transmission service. A utility cannot be required to build to an N-1-1 standard to satisfy reliability requirements and also be required to sell additional firm transmission service using a lower N-1 reliability standard. Such a situation would create an untenable situation where reliability standards force construction that the utility is then required to make available for sale pursuant to the provisions of the OATT and, once sold in accordance with the OATT, results in the utility being out of compliance with the reliability requirement. Requirement P2.1 in the table will have direct impact on local load reliability but not grid reliability. For example, a long line

Organization	Question 15:	Question 15 Comments:
		in a radial configuration due to a single contingency would only impact the reliability in a local area. Any implementation plan should consider all aspects of obstacles that Transmission owners will encounter including, ROW and land acquisition delays, inflationary impact on raw materials and other resources, capital funding constraints and associated regulatory lag, etc. Category P6 prescribes what is effectively an n-2 criteria for offering firm transmission service by not allowing the curtailment of firm transmission service as a system adjustment. Many areas are limited in how much local generation is available for re-dispatch as a system adjustment and thus compliance would be realized only by costly transmission construction by TPs.
Response: The SDT is striving to develop a standard that appropriately supports BES reliability and has industry consensus. The SDT is cognizant of the cost factors involved here and is taking them into consideration in its deliberations. The SDT agrees that clarification regarding Firm Transmission Service and Non-Consequential Load Loss is necessary. Footnote # 10 has been added to the end of Table 1: **Footnote #10** – <u>Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.</u> The SDT agrees that the Implementation Plan should consider matters you have listed. Nevertheless, the SDT feels that for this event (explained in detail in the footnote 8 of draft 3 of this Standard) interruption of neither firm nor Non-Consequential Load should be allowed for any BES voltage level, i.e., above or below 300 kV. This is consistent with FERC Order 693 that does not allow dropping Non-Consequential firm Load following any single Contingency. The SDT agrees that clarification regarding treatment of Firm Transmission Service and Non-Consequential Load Loss during adjustment is necessary. Footnote 10 in draft 3 of the Standard provides clarification.		
BPA Transmission Reliability Program	B — Unsure about supporting the revised standard	We are unsure about supporting the revised standard. A couple of additional concerns are described below. The purpose of the Standard is not clearly defined. There should be more clarity given to what reliability means in the context of these standards (e.g. minimize load loss for more probable contingencies, etc.). Regarding the terms "interruption of firm transmission service", there needs to be clarification of what "Interruption" means. Does it include curtailment needed after a particular contingency and adjustments? There also needs to be clarification on what "Firm Transmission Service" means. Two points: 1) the NERC definition states "highest quality of service offered to customers under a filed rate schedule that anticipates no planned interruption." The Standard implies anticipation of "unplanned' interruption for certain contingencies. 2) Is this referring to a transmission product as defined in FERC Order

Organization	Question 15:	Question 15 Comments:
		890, or firm transfers modeled for the conditions being studied? One way to interpret the intent, is the firm transfers being modeled for the conditions in the powerflow, to meet demand that would result in load not being served if that firm transfer were curtailed. If there is other generation in the system that could increase to meet the load, if the transfer being modeled is interrupted, then interruption of firm transmission service should be allowed for P1 through P5 contingencies in the table.
Response: The SDT believes that the Purpose under A.3 adequately captures the main intent which is to develop a "Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies." Footnote # 10 has been added to the end of Table 1 to reflect that curtailment or interruption of Firm Transmission Service will be allowed in preparation for the next Contingency. However, until the next Contingency occurs, System performance will need to meet the requirements for Event P1. As such, the proposed standard will not allow loss of any Non-Consequential Load, except for contracted Interruptible Loads, in preparation for the next Contingency. "Firm Transmission Service" is a NERC defined term and is also addressed by FERC in OATT. **Footnote #10** – Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch, is allowed both as a System adjustment (as identified in the column titled 'Initial System Conditions') and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources must be considered. Where Facilities external to the Transmission Planner's planning region are relied upon, Facility Ratings in those regions must be considered.		
PPL EnergyPlus	A — Generally support the revised standard	
Response: Thank you for your support.		

Consideration of Comments on Third Draft of Standard TPL-001-1 — Project 2006-02

The Assess Transmission Future Needs Standard Drafting Team thanks all commenters who submitted comments on the third draft of the TPL-001-1 standard. This standard was posted for a 45-day public comment period from May 26, 2009 through July 9, 2009. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 85 sets of comments, including comments from more than 170 different people from over 85 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Assess-Transmission-Future-Needs.html

Due to industry comments and continuing review of Order 693 directives applicable to TPL, changes have been made to the following:

Definitions: Consequential Load Loss, Non-Consequential Load Loss, and Year One

Requirements: R1 and parts 1.1, 1.1.1, 1.1.2, 1.1.3, 1.1.4, 1.1.5, and 1.1.6; R2 and parts 2.1, 2.1.3, 2.1.4 (and bullets 1, 3, and 7), 2.1.5, 2.1.6, 2.2, 2.2.1, 2.3, 2.4, 2.4.1, 2.4.3 (and bullets 1 and 3), 2.5, 2.6.1, 2.6.2, 2.7, 2.7.1 bullet 2, 2.7.2, 2.7.5, 2.7.6, 2.8, 2.8.2, 2.9; R3 and parts 3.1, 3.2, 3.3, 3.3.2, 3.3.3, 3.3.4, 3.4, 3.4.1, 3.5, 3.6; R4 and parts 4.1, 4.1.1, 4.1.2, 4.1.3, 4.2, 4.3, 4.3.2, 4.3.3, 4.3.4, 4.4, 4.4.1, 4.5; R5, R6, R7; R8 and part 8.1.

Measures: M1, M5, M7, and M8.

VSLs: R1, R2, R3, R4, R5, R6, R7, and R8.

Table elements: Header notes ‘a’, ‘c’, ‘f’, and ‘k’; P4, P7; extreme event ‘a’, steady state 1, Stability 1; footnotes: 2, 3, 4, 7, 9, 10, and 11

Implementation Plan

In addition, the SDT has reformatted the standard to meet the latest guidelines.

The SDT feels that the volume and scope of these changes warrants a fourth posting of this standard.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. Requirement R1 — Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: The SDT has made several clarifying changes to Requirement R1 and its various parts based on industry comments. The major changes made were to delete the phrase "including requirements of regulatory authorities and other legal obligations" from Requirement R1, the addition of "existing facilities' to the parts of Requirement R1, changing 'planned' outages to 'known' outages, combining the part calling for Firm Transmission Service and Interchange, and clarifying the final part as to the use of resources. Measure M1 was revised to provide greater clarity. The VSLs for Requirement R1 have been revised to match the new wording in the requirement.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

1.1 System models shall represent:

1.1.1 Existing Facilities

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.

1.1.3 New planned Facilities and changes to existing Facilities

1.1.4 Real and reactive Load forecasts

1.1.5 Known commitments for Firm Transmission Service and Interchange

1.1.6 Resources required to supply Load

M1 Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models, using the latest data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R1 VSL	The responsible entity's System model failed to represent one of the Requirement R1, parts 1.1.1 through 1.1.6	The responsible entity's System model failed to represent two of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not use the latest data consistent with the data provided in accordance with the MOD-010 and	The responsible entity's System model failed to represent three of the Requirement R1, parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not represent projected System conditions as described in Requirement

		MOD-012 standards and other sources, including items represented in the Corrective Action Plan.		R1.

Organization	Question 1 Comment
Dominion - Electric Transmission	R1 - Dominion questions the legal authority NERC has to include the recently inserted language "including requirements of regulatory authorities and other legal obligations." This language is too broad and far exceeds the jurisdiction of NERC's mission. R1.1.5 - Dominion has seen base case models built by other transmission entities which do not include area interchanges for all areas and must be solved with area interchange "turned off". Would these base case models be in violation of R.1.1.5?

Response: The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

> **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The SDT believes that the base cases should include any area interchange that is planned between utilities. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

> **1.1.5** Known commitments for Firm Transmission Service and Interchange

Organization	Question 1 Comment
Northeast Power Coordinating Council	R1--There needs to be some direction provided on the initial conditions used in the assessment. This guidance should include discussion as to whether or not representations of generator forced outages are to be represented in the base case or if they are addressed through the sensitivity testing (Could add R1.1.7 Reasonable representations of unplanned generator outages.) Additionally, the standard is also silent on the treatment of system transfers, both internal and external, as to how they should be modeled in the base case. For some areas, their current practice is to include heavy system stresses in their base case, which leaves little for sensitivity testing. It is unclear if this practice works within the purview of this standard. Guidance is needed on how to treat base case generation dispatch and system transfers. The inclusion of "requirements of regulatory authorities and other legal obligations" is not understood. Even if some version of this language is kept in the final standard, it seems to belong in R2 rather than R1. "Simulate" should be changed to "incorporate". R1.1.1 Priority comment. Only known long-term outages of generation and transmission should be required to be modeled.

Organization	Question 1 Comment
	R1.1.2 comment - Do we need to have the list of equipment to model? How are circuit breakers, and other equipment modeled? Also, what should be the level of detail and the form that Protection System Equipment and Control Devices be modeled? We recommend deleting the list. Make R1.1.2 simply read as follows: R1.1.2--Projected system configuration, taking into account new planned Facilities and changes to existing Facilities, for each year of the Near-Term and Long-Term Transmission Planning Horizon. R1.1.5 comment What specifically needs to be modeled under Interchange "R1.1.6 comment " This needs further definition or it should be deleted. It is not clear what a network resource required to supply load is. Does this refer to Network Resource per FERC LGIP?

Response: The SDT believes that the outages should be modeled to insure the System reliability during the outage durations. If a Transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-Contingency. All performance criteria would then apply to that new base case. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.

Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

1.1.5 Known commitments for Firm Transmission Service and Interchange

The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within their respective areas for performing the studies needed to complete their Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The SDT has changed the word "simulate" to "represent" in Requirement R1.

Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices is typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list as they are already covered in the Corrective Action Plan under Requirement R2, part 2.7. Existing Facilities are now shown under Requirement R1, part 1.1.1.

1.1.1 Existing Facilities

Interchange is defined in the NERC glossary as "energy transfers that cross Balancing Authority boundaries" while Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include

Organization	Question 1 Comment
known commitments for Firm Transmission Service and Interchange. The intent of the SDT was that this includes network resource as per the FERC LGIP but that it is not limited to that. The SDT has clarified the wording for Requirement R1, part 1.1.6. **1.1.6** Resources required to supply Load	
Transmission Planning	R1.1. COMMENT: Should read: Models for performing the studies needed to complete the Planning Assessment shall represent: instead of Models for the Planning Assessment shall represent: R1.1.1. COMMENT: Should the requirement specify which known outages should be modeled? For example, would it be considered incomplete and therefore a violation if a known generator maintenance outage with a one week duration is not included (not modeled off-line) in a case that represents a full summer season at peak conditions? Please provide guidelines as to what duration outages should be modeled in representative planning horizon cases. (i.e. one day, several days, one week, one month, in a case that represents a significantly longer time period.) R1.1.2. COMMENT: Should add Transformers to this list; COMMENT: What is meant by “represent” - Planning models do not typically include explicit Circuit breaker modeling. The planning models used for power flow, dynamics and short circuit analysis represent the power system with busses and branches. The effect of circuit breakers is taken into account as part of contingency modeling. Including circuit breakers as a sub-requirement is likely to result in transmission planners being required to demonstrate that circuit breakers are modeled. Explicit representation of circuit breakers with existing software would result in major convergence problems due to large number of low impedance branches. COMMENT: Should clarify "Protection System equipment" to apply only to system stability models. Does this mean all relays on the system must be included in the dynamics modeling? While a certain limited number of protective relays can be modeled with the software used for dynamics, it is not practical to model more than a very small percentage of the protection systems used in the BES. Including protective relays as a sub-requirement is likely to result in transmission planners being required to demonstrate that all protective relays are modeled which is an impossible task. The modeling of protective relays should be caveated with as deemed appropriate. COMMENT: "Control devices" Should be specific. Is this for Phase Angle Regulators (PAR), Synchronous Condensers, Static Var Compensators (SVC), exciters, governors etc? Control devices should be specifically defined as the following: PAR, SVC, HVDC. COMMENT: "New technologies" seems too broad. Needs to be better defined. Planning models may not have the capability to adequately model new technologies. R1.1.4. Firm Transmission Service COMMENT: Should add that is expected to be utilized in the study case scenario because not all Firm Transmission Service can be included in every study case model. Some firm transmission reservations (Network Resources that could be Reserves) are used optionally depending upon the availability of other Network resources. The following apply to all VRF, Time Horizon, Measure, Data Retention, and VSL for all requirements in the standard.VRF: Agree. No comment.

Organization	Question 1 Comment
	Time Horizon: COMMENT: Long-Term Planning This is confusing. Is it only the newly defined Long-Term Transmission Planning Horizon? Shouldn't it include the Near-Term Transmission Planning Horizon Suggest Long-Term and Near-Term Transmission Planning Horizon as used in definitions. Measure: Agree. No comment. Data Retention: Agree. No comment. VSL: Are bullets in requirements all required? (I.e. If circuit breakers are not explicitly modeled, as the bullet list in R1.1.2 seems to indicate, is it a violation?) What is meant by did not simulate projected System conditions as described in R1. How are projected System conditions criteria described in R1?

Response: The SDT has reworded the requirement.

1.1 System models shall represent:

Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list as they are already covered in the Corrective Action Plan under Requirement R2, part 2.7**.**

The SDT has revised Requirement R1, part 1.1.2 to provide clarity.

New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the equipment list under Requirement R1, part 1.1.2 since these are already covered in the Corrective Action Plan under Requirement R2, part 2.7

Models are only specific to the case study. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

1.1.5 Known commitments for Firm Transmission Service and Interchange

The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made.

Mitigation Time Horizon - The time horizons available for mitigating a violation to a requirement include the following::

- **Long-term Planning** — a planning horizon of one year or longer.

Organization	Question 1 Comment

- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Thank you for your response on Measures and Data Retention.

The SDT has removed the equipment list. Transmission lines, generators, and reactive power devices were removed from the equipment list due to already being included in MOD standards. Circuit breakers, Protection System equipment, and control devices were removed from the equipment list since these items are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note c in Table 1. New technologies were removed from the list as they are already covered in the Corrective Action Plan under Requirement R2, part 2.7.

The SDT has deleted the equipment list.

The SDT has replaced "simulate" with "represent" under the Severe VSL category for R1.

R1 VSL	The responsible entity's System model failed to represent one of the Requirement R1, parts 1.1.1 through 1.1.6	The responsible entity's System model failed to represent two of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not use the latest data consistent with the data provided in accordance with the MOD-010 and MOD-012 standards and other sources, including items represented in the Corrective Action Plan.	The responsible entity's System model failed to represent three of the Requirement R1, parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not represent projected System conditions as described in Requirement R1.

Requirement R1 contains the requirements needed for creating proper base cases.

SERC Engineering Committee Planning Standards	R1.1.2: In bullet three of R1.1.2, are bus-tie circuit breakers to be represented in the models? Typically circuit breakers are included in the contingency definitions along with the protection system equipment used in the power flow models. The number of zero impedance branches which can presently be modeled using PSS/E software is limited to 4000. Also, the number of buses

Organization	Question 1 Comment
Subcommittee	included in the power flow models would increase with additional breaker modeling. Protection System Equipment: The SDT stated during its June 30th Webinar that protection system equipment need not be explicitly represented in models, but had difficulty in determining adequate wording for the proposed sub-requirement. Because protection system action is described in R3.3.1, R3.3.4, R4.3.1, and R4.3.3 we suggest that protection system equipment be removed from the list in R1.1.2.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.	
Modesto Irrigation District	Comment: Are all bullets under R1.1.2 required to be explicitly modeled or are the effect of the devices or the effect of the removal of the devices to be modeled? We don't explicitly model circuit breakers or explicitly model protection system equipment in the steady state model. R1.1.4 should refer to expected transfers to be consistent with the bullet under R2.1.3. Please explain the difference between R1.1.4 and R1.1.5
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. Requirement R1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange Interchange is defined in the NERC glossary as "energy transfers that cross Balancing Authority boundaries" while Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption."	
OPUC	1. Requirement R1 Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.Comments: A: Language in R1.1.2 still needs further clarification. Base case models do not clarify modeling required for the effect or absence of circuit breakers, protection system equipment and control devices. B: Clarity would be increased were R1.1.4 to refer to expected transfers rather than Firm Transmission Service, permitting the elimination of then redundant R1.1.5 C: Removing "including requirements of regulatory authorities and other legal obligations" at the end of R1 would also eliminate redundant text.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices	

Organization	Question 1 Comment
are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. **1.1.3** New planned Facilities and changes to existing Facilities Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective areas for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	
Bonneville Power Administration PacifiCorp Deseret Generation & Transmission SRP Southern California Edison Company Pacific Gas and Electric Co, NV Energy San Diego Gas and Electric Co California ISO	The language in R1.1.2 needs to be clarified. Many of these facilities are not explicitly included in the models in the base cases (circuit breakers, protection system equipment, control devices). The language should be clarified to require modeling the effect of the devices or the effect of the removal of the devices where it is expected to impact the study outcome. Clarity is needed to explain the difference between R1.1.4 and R1.1.5. Expected interchange can be reasonably projected, but information on Firm Transmission Service is not always known or reasonably projected for future cases. For consistency with the 2nd bullet under R2.1.3, R1.1.4 should refer to expected transfers rather than Firm Transmission Service. With this change, R1.1.4 and R1.1.5 would be redundant and one should be deleted. We disagree with the inclusion of the words including requirements of regulatory authorities and other legal obligations at the end of R1. Entities already are required to do this. It does not need to be included in the standard.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. Interchange is defined in the NERC glossary as "energy transfers that cross Balancing Authority boundaries" while Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include	

Organization	Question 1 Comment
known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	
SERC Engineering Committee Dynamics Review Subcommittee (DRS)	There may be a potential conflict between MOD-010 and MOD-012 and legal documents such as Interconnection Agreements e.g. IA may specify a capacity level that exceeds the reported test levels. In the case of such conflicts, which one should rule? An order of precedence is needed as part of this requirement. Suggest adding terminal equipment to the list of planned facilities. The phrase, for each year of the Near-Term and Long-Term Transmission Planning Horizon, should be revised to remove each year because there may not be studies in each year.
Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective areas for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The reference to "year" has been removed from Requirement R1, part 1.1.2 (now part 1.1.3). **1.1.3** New planned Facilities and changes to existing Facilities	
SERC Engineering Committee Reliability Review Subcommittee (RRS)	In bullet three of R1.1.2, are bus-tie circuit breakers to be represented in the models? Typically circuit breakers are included in the contingency definitions along with the protection system equipment used in the powerflow models. The number of zero impedance branches which can presently be modeled using PSS/E software is limited to 4000. Also, the number of buses included in the

Organization	Question 1 Comment
	powerflow models would increase with additional breaker modeling. In R1.1.2, don't we need to also represent the existing transmission system, and not just changes to the existing system In R1.1.2, does the phrase for each year signify each year for which assessment work was performed, or each year of the Near-Term and Long-Term Transmission Planning Horizon? The phrase, for each year of the Near-Term and Long-Term Transmission Planning Horizon, should be revised to remove each year because there may not be studies in each year. In bullet five of R1.1.2, what protection system equipment is to be included in the stability models In bullet seven of Requirement R1.1.2, what "new technologies" are to be represented in the models Concerned about only having one year to implement all new modeling requirements - especially the additional relay requirements noted in R1.1.2. The SDT stated during its June 30th Webinar that protection system equipment need not be explicitly represented in models, but had difficulty in determining adequate wording for the proposed sub-requirement. Because protection system action is described in R3.3.1, R3.3.4, R4.3.1, and R4.3.3 we suggest that protection system equipment be removed from the list in R1.1.2. There may be a potential conflict between MOD-010 and MOD-012 and legal documents such as Interconnection Agreements e.g. IA may specify a capacity level that exceeds the reported test levels. In the case of such conflicts, which one should rule? There may be a need to add definitions to discern the difference between planned and proposed projects. Suggest replacing circuit breakers in R1.1.2 with terminal equipment since circuit breakers are covered by Protection System Equipment. Does there need to be a reference in R1 to NERC Reliability Assessment Guidebook version 1.2 on pp 17-18 for everyone to use a 50/50 load forecast for inclusion in the planning models?? R1.1.4 Firm Transmission Service - a single source can have transmission service to multiple sinks, and can be associated with transmission service in excess of the capacity of the source. There is a lack of clarity regarding the means by which Firm Transmission Service, a marketing term, is to be included in planning models. For example, should the standard define how to model wind farms (100% - off-peak and 20% on-peak, based on firm capacity from the wind generators, or other dispatch levels)? Not sure if this is applicable to Requirement 1 or 2.

Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.

The SDT has revised Requirement R1, part 1.1.1 to include "existing system".

1.1.1 Existing Facilities

The reference to "year" has been removed from Requirement R1, part 1.1.2 (now part 1.1.3)

Organization	Question 1 Comment
1.1.3 New planned Facilities and changes to existing Facilities Requirement R1, part 1.1.2 (now part1.1.3) has been revised as described above. New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the equipment list in Requirement R1, part 1.1.2 (now part 1.1.3) since these are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. In Draft 1, the SDT proposed using the terms "planned" and "committed" (similar to your proposal of proposed and planned) to distinguish the "firmness" of projects. Based on industry comments, the SDT eliminated the terms from Draft 2. No change made. Requirement R1, part 1.1.2 (now part1.1.3) has been revised as described above. The SDT does not believe that a reference is needed to the NERC Reliability Assessment Guidebook since most utilities are using at least a 50/50 Load forecast as a minimum. No change made. The SDT believes that all firm Transmission contracts should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
FirstEnergy Corp	As stated in prior comment periods, we hold the opinion that the TPL-001-1 standard should start from the premise that a valid system model exist based on MOD-010, MOD-012 and other FERC approved MOD standards that are not referenced by this TPL-001-1 standard. The inclusion of R1 introduces an overlap and potential for double jeopardy violations that need not occur. The TPL-001-1 standard should not delve into model building and keep to its core purpose of assessing future performance of the BES.Specific comments, Requirements of R1A. R1.1.2: The last bullet "New Technologies" is too vague and should be struck from the requirement. B. R1.1.4: It is not well understood how "Firm Transmission Service" would be evaluated by a compliance auditor when reviewing a simulation model. The models contain agreed upon Interchange Transactions between BA areas, but no details are provided to reflect individual Firm Transmission Service arrangements. In reality only the net-Interchange values between BA areas are reflected in the simulation models. C. R1.1.6: FE believes this requirement would be more accurately assigned to the Resource Planner or Load Serving Entity and not the Transmission Planner.

Organization	Question 1 Comment
	We agree with the stated Measures, VRF, Time-Horizon, Data Retention and VSL of requirement R1

Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

> **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

> **1.1.5** Known commitments for Firm Transmission Service and Interchange

The SDT believes that the Transmission Planner/Planning Coordinator is responsible for incorporating this information into the System models. No change made.

Thank you for your response on Measures et al.

Organization	Question 1 Comment
IRC Standards Review Committee	(1) R1.1.1 requires that models shall represent planned outages of generation and transmission facilities, if specifically known. Does this allow or require a PC/TP to include outages due to maintenance and due to construction programs where certain facilities are out of service during phases of construction as part of the Assessment? Such maintenance and construction schedules are made but may not be finalized over the planning horizon. Further, are planned outages to be treated as creating a "normal system condition" or is the planned outage a contingency from which system adjustments are made prior to subsequent events" (2) MOD 10 and 12 are based on requirements determined by the RRO in MOD 11 and 13 respectively. Is this appropriate? Further, the PC is not an applicable entity in MOD 10 and 12. (3)What are "other data sources"?

Response: The SDT believes that the outages (if known) should be modeled to insure the System reliability during the outage durations. If a Transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-contingency. All performance criteria would then apply to that new base case. Requirement R1, part 1.1.2 (now part 1.1.3) has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

Organization	Question 1 Comment
1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. The SDT understands that MOD-010 and -012 are impacted by MOD-011 and -013. The Planning Coordinator is not applicable - but has to utilize data provided by others such as in MOD-010 and -012.No change made. The SDT had removed the reference to "other data sources" under Requirement R1. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	
TVA System Planning	The phrase, for each year of the Near-Term and Long-Term Transmission Planning Horizon, should be revised to remove each year because there may not be studies actually required in each year. The SDT stated during its June 30th Webinar that protection system equipment need not be explicitly represented in models, but had difficulty in determining adequate wording for the proposed sub-requirement. Because protection system action is described in R3.3.1, R3.3.4, R4.3.1, and R4.3.3 we suggest that protection system equipment be removed from the list in R1.1.2. If R1.1.2 is not removed, TVA is concerned about the level of resources that will be required to model these additional relay requirements in the one year allowed in the Implementation Plan. In bullet three of R1.1.2, are bus-tie circuit breakers to be represented in the models? Typically circuit breakers are included in the contingency definitions along with the protection system equipment used in the powerflow models. In bullet seven of Requirement R1.1.2, what "new technologies" are to be represented in the models?
Response: The reference to "year" has been removed from Requirement R1, part 1.1.2 (now part 1.1.3). **1.1.3** New planned Facilities and changes to existing Facilities The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. See Requirement R1, part 1.1.2 comment above New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the Requirement R1, part 1.1.2 list (now part 1.1.3) and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.	
Southern Company	The VSLs for Requirement R1 incorporates several sub-requirements but neglects one of the three components of the main requirement. Consider that R1 requires the TP and RC to (a) maintain System models, (b) use data consistent with certain MOD standards, and (c) simulate projected System conditions. Because the first component is not a part of the proposed VSL and the

Organization	Question 1 Comment
	purpose of this standard mentions a broad spectrum of System conditions, the recommendation is to add maintaining the system model into the VSLs for R1. R1.1.3 uses the terminology real and reactive Demand of Load. We suggest striking the word "Demand" because it refers only to real power. We recommend the the SDT limit R1 to load flow and stability models. Does R1 apply to short circuit models? If so does this imply that the short circuit model must be the same as the load flow model?
Response: The SDT revised the VSLs for Requirement R1 to align with the changes made to the requirement – note that the revised R1 does not use the word, “simulate.” The SDT has modified Requirement R1, part 1.1.3 (now part 1.1.4). **1.1.4** Real and reactive Load forecasts The SDT believes that Requirement R1 also contains some requirements that are necessary for short circuit cases but R1 does not require the models to be the same, since different software applications may be used. No change made.	
United Illuminating Northeast Utilities ISO New England, Inc. Central Maine Power Company	R1 Priority Comment- There needs to be some direction provided on the initial conditions used in the assessment. This guidance should include discussion as to whether or not representations of generator forced outages are to be represented in the base case or if they are addressed through the sensitivity testing (Could add R1.1.7 Reasonable representations of unplanned generator outages.) Additionally, the standard is also silent on the treatment of system transfers, both internal and external, as to how they should be modeled in the base case. For some areas, their current practice is to include heavy system stresses in their base case, which leaves little for sensitivity testing. It is unclear if this practice works within this standard. R1.1.1 Priority comment R1.1.1 should be removed. It seems like there is an overlap between the requirements of this standard and Operational Planning studies with respect to known outages. Planned outages are addressed by our Operational Planning processes and Transmission Operating Procedures removing the need for this to be incorporated into Planning Assessments. In addition, outages are not generally known years in advance R1 Comment We do not understand what it means to include requirements of regulatory authorities and other legal obligations. Even if some version of this language is kept in the final standard, it seems to belong in R2 rather than R1. R1.1.2 comment - Do we need to have the list of equipment to model? How do we model circuit breakers, etc? We recommend deleting the list. Make R1.1.2 simply read: R1.1.2 New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon. R1.1.5 comment What specifically needs to be modeled under Interchange R1.1.6 comment This needs further definition or it should be deleted. It is not clear what a network resource required to supply load is. Does this refer to Network Resource per FERC LGIP?

Organization	Question 1 Comment
Response: The SDT believes that the outages should be modeled to insure the System reliability during the outage durations. If a Transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-contingency. All performance criteria would then apply to that new base case. Requirement R1, part 1.1.2 (now part 1.1.3) has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months. **1.1.3** New planned Facilities and changes to existing Facilities Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months. **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. Interchange is defined in the NERC glossary as "energy transfers that cross Balancing Authority boundaries" while Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.6 has been broadened while still incorporating Network Resources. **1.1.6** Resources required to supply Load	
System Protection and Transmission Planning Department	R1 the requirement to maintain System models for performing the studies is redundant with MOD-010, and should be moved to MOD-010. The phrase that requires model data used in Studies used for Annual Assessments be consistent with data submitted under MOD-010 seems OK. R1.1.2, a sub-requirement of R1.1, states that models for Planning Assessments shall represent "new planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon". Is this a requirement for maintaining a case representing every year of the near-term and long-term planning horizons (i.e. 10 cases)? We do not think that is what the SDT had in mind. If all that is required to remain cognizant of Facility In-Service dates so that topology is reliable, please so state. To make this read clearer, we suggest you take out the phrase for each year . Regarding bullet 5 of R1.1.2, does inclusion of Protection System equipment require modeling of all relays in dynamic studies? The NERC definition of Facility pertains to equipment energized at primary voltages, not Protective System equipment. We

Organization	Question 1 Comment
	suggest the Protective Systems be eliminated from this list. To make this read clearer, we suggest you delete text and bullet items following Transmission Planning Horizon. Regarding R1.1.2 bullet items: The bullets list examples of Facilities. This list is not needed, since the term Facility is already defined in the NERC Glossary. If you do not remove all bullets, then we warn you that the bullet "New Technologies" can be interpreted to cover a broad range of topics by an auditor and is not clearly defined by NERC, so we cannot visualize measurable documentation.

Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. No change made.

Thank you for your response.

The reference to “year” has been removed from Requirement R1, part 1.1.2 (now part 1.1.3).

1.1.3 New planned Facilities and changes to existing Facilities

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The bulleted list has been deleted.

Organization	Question 1 Comment
PPL Energy Plus	PPL agrees with the requirement that regulatory and legal requirements need to be respected in planning studies. Also, Requirement R1.1.6 appears to conflict with FERC Pro-forma OATT Section 30.4 in that Network Resource output should not be limited as this Requirement states.

Response: The SDT has removed “including requirements of regulatory authorities and other legal obligations” since utilities already have to abide by such requirements.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

Requirement R1, part 1.1.6 has been broadened while still incorporating Network Resources.

1.1.6 Resources required to supply Load

Organization	Question 1 Comment
Western Area Power Administration	Since the modeling data used for the Planning Assessment is initially created and governed per Mod-10 & Mod-12 Standards, this requirement should be clarified to include maintain revisions of the modeling data required to perform the Planning Assessment

<table>
<tr><th>Organization</th><th>Question 1 Comment</th></tr>
<tr><td></td><td>and not just "maintain system models for performing the studies needed to complete their Planning Assessment?.</td></tr>
<tr><td>Orlando Utilities Commission</td><td>-This section is very clear. <tr><td>Kansas City Power & Light</td><td>R1 states that the models used in these studies shall be consistent with data provided through MOD-010 and MOD-012. The data submitted for these are updated on a schedule provided by the RRO and not necessarily reflective of any emerging changes that may have occurred between the MOD data collection cycle. The requirement should allow for exceptions to allow the most recent information to be included in the TPL studies.</td></tr>
<tr><td colspan="2">Response: The SDT has modified Measure M1 to use the latest data available.

M1 Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models, using the latest data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.</td></tr>
<tr><td>Tampa Electric</td><td>R1 Ensure that statement reflects that TP and PC are only responsible for their planning area.

R1.1.2 Add transformers to list and clarify modeling of circuit breakers and protection system equipment. Models should reflect the effect of this equipment, not the actual equipment.

R1.1.4 Models should only reflect firm transmission service that is expected to be utilized in the study case.

Consider changing effective dates of all requirements to be the same date so that you do not have to meet two standards during the same time period.</td></tr>
<tr><td colspan="2">Response: The SDT had modified Requirement R1 to state that the Transmission Planner/Planning Coordinator are each responsible for maintaining System models for its respective area.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement r4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The SDT believes that all firm Transmission should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.</td></tr>
</table>

Organization	Question 1 Comment
1.1.5 Known commitments for Firm Transmission Service and Interchange The SDT believes that certain steps need to be taken in succession to allow utilities to progress toward meeting the new requirements - while not placing an undue burden for utilities to meet all the new requirements at the same time. Also additional time is needed for many utilities to meet "raising the bar" requirements that may be required and which could take considerable lead time. No change made.	
Florida Reliability Coordinating Council, Inc - Transmission Working Group	R1 and M1: Consider clarifying that it is not the TP or PC responsibility to independently verify the consistency of the System models for portions of the Bulk Electric System outside of the TP or PC planning area (related to not using data consistent with data submitted as part of MOD-010 and MOD-012, each TP and PC should not have to review the data submitted by those outside of its planning area, but only its own planning area). Please Clarify the phrase Models shall use data consistent with .MOD-010 is the intent for the data to be identical to the data provided under MOD-10 and MOD-12, or consistent meaning that the data might be older or newer depending on when the assessment took place vs when the data was submitted. R1.1 Consider changing Assessment (which does not include models) or re-wording to Models for performing the studies needed to complete the Planning Assessment shall represent:?R1.1.1 Brings clarity to the question regarding planned outages. R1.1.2: Consider adding “Transformers” to the list of facilities. R1.1.2, please clarify what the drafting team intentions are for Circuit Breakers. Planning models used for power flow, dynamics and short circuit do not include circuit breakers. Modeling circuit breakers would cause convergence problems in the models due to that large number of zero impedance line sections. We sugges eliminating circuit breaker from the bullet list. R1.1.2 Protection System equipment this should be clarified to only apply to system stability models. The modeling of protective relays should be caveated with as deemed appropriate. We suggest eliminating Protection System equiptment from the bullet list. R1.1.4 Consider adding that is expected to be utilized in the study case scenario not all Firm Transmission can be included in all studies and are only used upon the availability of other resources . Consider changing the effective dates of R1 and R7 to take effect at the same time as R2 through R6 so you do not have to meet two standards during the same time period. Otherwise, clarify how the effective date impacts which version of the standard is to be used in an assessment before a scheduled compliance audit.
Response: The SDT has modified Requirement R1 to state that the Transmission Planner and Planning Coordinator are each responsible for maintaining System models for its respective area. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has incorporated these additional requirements with the intent that they will be removed from the TPL standard when they are incorporated into the MOD standards at a	

Organization	Question 1 Comment
later date. The SDT has modified Measure M1 to use the latest data available. **M1** Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models, using the latest data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1. The SDT agrees and has reworded Requirement R1, part 1.1. **1.1** System models shall represent: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange The SDT believes that certain steps need to be taken in succession to allow utilities to progress toward meeting the new requirements - while not placing an undue burden for utilities to meet all the new requirements at the same time. Also additional time is needed for many utilities to meet "raising the bar" requirements that may be required and which could take considerable lead time. No change made.	
FMPA	R1, consider clarifying that it is not the TP or PC responsibility to independently verify the consistency of the System models for portions of the Bulk Electric System outside of the TP or PC planning area (related to not using data consistent with data submitted as part of MOD-010 and MOD-012, each TP and PC should not have to review the data submitted by those outside of its planning area, but only its own planning area). R1.1.2: Consider adding Transformers to the list of facilities. R1.1.2, please clarify what the SDTs intentions are for Circuit Breakers. Planning models used for power flow, dynamics and short circuit do not include circuit breakers. Modeling circuit breakers would cause convergence problems in the models due to that large number of zero impedance line sections. We suggest clarifying that the intent is to develop planned Facility Ratings in the models to reflect new Circuit Breakers, and to reflect the location and timing of circuit breakers in contingency lists, and not to model the actual circuit breakers. R1.1.2 "Protection System equipment should be clarified to only apply to system stability models. The modeling of protective relays should be caveated with as deemed appropriate. We suggest clarifying that the intent is, for power flow and short circuit studies, Protection System Equipment would be incorporated into Facility Ratings and the contingency list. And we suggest further clarifying that the intent is the same for Stability Studies, with the addition of modeling Protection System equipment that could significantly impact stability response (e.g., out-of-step relaying) as deemed appropriate through engineering judgment. R1.1.4 Consider adding "that is expected to be utilized in the study case scenario" not all Firm Transmission can be included in all studies and are only used upon the availability of other resources (for instance, if there are two firm point-to-point contracts in opposite directions across the same Interchange, both probably ought not to be modeled at the same time). Consider changing the effective dates of R1 and R7 to take effect at the same time as R2 through R6 so you do not have to meet

Organization	Question 1 Comment
	two standards during the same time period. Otherwise, clarify how the effective date impacts which version of the standard is to be used in an assessment before a scheduled compliance audit.
Response: The SDT had modified Requirement R1 to state that the Transmission Planner/Planning Coordinator are each responsible for maintaining System models for its respective area. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement r4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that all firm Transmission should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange The SDT believes that certain steps need to be taken in succession to allow utilities to progress toward meeting the new requirements - while not placing an undue burden for utilities to meet all the new requirements at the same time. Also additional time is needed for many utilities to meet "raising the bar" requirements that may be required and which could take considerable lead time. No change made.	
Progress Energy Carolina (PEC)	PEC would like clarification on the following: "Models for the Planning Assessment shall represent: Circuit Breakers, Protection System Equipment, etc." The clarification should state that the models do not have to explicitly include these elements as long as their effect can be modeled.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.	
Gainesville Regional Utilities	Concerning the effective dates of R1 & R7, I suggest that you move them to be effective at the same time as R2 through R6 so you will not have to try to meet two standards during the same time period. Effective Date: Clarify how the effective date impacts which version of the standard (and it reference numbering) is to be used in an assessment just before (in cycle) a scheduled compliance audit. Suggest that the term "Corrective Action Plan" be retitled to "Improvement Action Plan" because the first implies that the situation is "wrong or incorrect" which may not be the case.

Organization	Question 1 Comment
Response: The SDT believes that certain steps need to be taken in succession to allow utilities to progress toward meeting the new requirements - while not placing an undue burden for utilities to meet all the new requirements at the same time. Also additional time is needed for many utilities to meet "raising the bar" requirements that may be required and which could take considerable lead time. No change made. The Effective Date of the requirements in force at the time the Planning Assessment is completed will dictate which requirements are the governing requirements. The SDT believes that the term "Corrective Action Plan" (a defined term) is sufficient due to lack of comments received from industry requesting this change. No change made.	
JEA	Reword R1.1.2. New planned Facilities and changes to existing and old planned Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon where such Facilities affect the electric connectivity and topology of the system or affects the accurate simulation of system disturbance response where practical. [Delete bulleted list]Add R1.2. Where it is not practical to model all Facilities composing the electric system connectivity and topology, consideration of those Facilities and their affect on the model simulations shall be documented in detail in the annual Planning Assessment where appropriate. This addition may not be necessary with rewording of R3.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard**.**	
NorthWestern Corporation NorthWestern Energy (NWE) (NWMT)	The system models that are described in MOD-010 Requirement1, MOD-011 Requirement 1, MOD-012 Requirement 1, and MOD-013 Requirement 1 do not address all the bulleted items under R.1.2. Circuit breakers, protection system equipment and control devices are not modeled. Rather, the effect of these devices, such as circuit breaker misoperation, thermal overload, etc., on the transmission system are modeled. The wording of these bullets should be corrected to match what is actually modeled. Firm Transmission Service, listed in R.1.1.4, is not specifically addressed in MOD-010. Requirement 1 of MOD-010 states existing and future Interchange Schedules as data requirements for steady-state modeling and simulation. Models in the West do not model Firm Transmission Service as such. It is difficult to know what the Firm Transmission Service will be in the future. This is particularly true in regions where there is a predominance of merchant generation and proposals for the interconnection of new merchant generation. It is more reasonable to estimate the expected interchanges. The definition for Interchange Energy transfers that cross Balancing Authority boundaries describes the modeling requirement better that the definition of Firm Transmission Service The highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruptions. The wording Expected Transfers" is used in R2.1.3 and R2.4.3. To maintain consistency, this term could be used in R.1.1.4 and could also be substituted in Table 1 for Firm Transmission. From a Planning perspective, since Firm Transmission cannot be determined from a study model. R1.1.4 and R1.1.5 should be deleted and replaced with a requirement to model expected transfers on interconnections with neighboring Balancing Authorities. For study purposes R.1.1.6 is not needed either. In the models, the load represented is served by the generators modeled. Network Resources are more in tune with local area studies that ensure that the network load can be served by the network

Organization	Question 1 Comment
	resources over available transmission. The words “including requirements of regulatory authorities and other legal obligations at the end of R1. does not need to be in the standard.

Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes.

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

Interchange is defined in the NERC glossary as “energy transfers that cross Balancing Authority boundaries” while Firm Transmission Service is “the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption.” Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

1.1.5 Known commitments for Firm Transmission Service and Interchange

The SDT believes that Requirement R1, part 1.1.6 is still required but it has been broadened.

1.1.6 Resources required to supply Load

The SDT has removed “including requirements of regulatory authorities and other legal obligations” since utilities already have to abide by such requirements.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions

Organization	Question 1 Comment
SMUD	R1: The requirement should end after the words "shall simulate projected System conditions.”. The following words should be deleted as it results in a clause that is overly broad and does not specify clear and concise reliability requirements: "including requirements of regulatory authorities and other legal obligations".

Response: The SDT agrees and has changed Requirement R1 accordingly.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

Organization	Question 1 Comment
Progress Energy Florida, Inc.	For R1.1.2, PEF has the following comments:T-T Transformers, as major components of the BES, should be on this list.PEF does not object to the inclusion of Circuit Breakers on this list, provided that representation is not required in steady state load flow

Organization	Question 1 Comment
	cases. Breaker failure scenarios can be extensively studied in the steady state and stability realms by removing from service the transmission facilities that such a breaker event would initiate.PEF assumes that the inclusion of Protection System Equipment applies only to Stability Analysis. As for breakers, relay failure scenarios can be extensively studied in the steady state realm by removing from service the transmission facilities that such a relay event would initiate. Additionally, PEF also assumes that a comprehensive modeling of all Protection System Equipment (e.g. Transformer Sudden Pressure Relays, Bus Diff Relays, etc.) in Stability Analysis is not required, since only a limited amount of relaying in dynamic modeling is needed to adequately model the system with respect to what transmission/generation components would trip for a given event.A lack of specificity on the term Control devices leaves it open to wide interpretation. The SDT should, in detail and/or with examples, state what is intended. The term New technologies is only acceptable for inclusion if provision is made for the fact that Planning analysis software often lags behind the design industry in getting new technologies modeled such that Planners can analyze them. For R1.1.4 on Firm Transmission Service: PEF assumes that the SDT understands that some firm transmission service is not always modeled in every case, depending upon the economics and availability of alternate resources.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that all firm Transmission should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
Xcel Energy	R1 states that the models used in these studies shall be consistent with data provided through MOD-010 and MOD-012. The data submitted for these are updated on a schedule provided by the RRO and not necessarily reflective of any emerging changes that may have occurred between the MOD data collection cycle. The requirement should allow for exceptions to allow the most recent information to be included in the TPL studies.
Response: The SDT has modified Measure M1 to use the latest data available. **M1** Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models, using the latest data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.	
Arizona Public Service Co	The language in R1.1.2 needs to be clarified. Many of these facilities are not explicitly included in the models in the base cases (circuit breakers, protection system equipment, control devices). The language should be clarified to require modeling the effect of

Organization	Question 1 Comment
	the devices or the effect of the removal of the devices only where it is expected to impact the study outcome. Clarity is needed to explain the difference between R1.1.4 and R1.1.5. Expected interchange can be reasonably projected, but information on Firm Transmission Service is not always known or reasonably projected for future cases. For consistency with the 2nd bullet under R2.1.3, R1.1.4 should refer to expected transfers rather than Firm Transmission Service. With this change, R1.1.4 and R1.1.5 would be redundant and one should be deleted. We disagree with the inclusion of the words including requirements of regulatory authorities and other legal obligations at the end of R1. Entities already are required to do this. It does not need to be included in the standard. VSL: Under Severe VSL Column: The last sentence The System model did not simulate projected System Conditions as described in Requirement R1 is vague and should be clarified. What is meant by did not simulate. Is it referring to gross errors or something else? We recommend that Sever VSL be assigned only if the Transmission Planner failed to do the planning assessment. Hence it should not apply to R1 at all since R1 is only related to modeling accuracy.

Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The SDT believes that transfers and Firm Transmission Service can actually be two separate items since Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

> **1.1.5** Known commitments for Firm Transmission Service and Interchange

The SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

> **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The SDT has replaced "simulate" with "represent" in the requirement, measure and under the Severe VSL category for Requirement R1. The SDT believes that the Severe level should be applied as noted in the VSL table since these cases are the basis for having an accurate planning assessment.

Organization	Question 1 Comment
New Brunswick System Operator	It is not clear how TP and PC are to coordinate activities. If R6 provided direction on individual and joint responsibilities then R6 should be referred to in each of the requirements which require TP and PC coordination. The VSL and Measurement for requirement R1 appears focused the number of subrequirements represented in the model. Ideally the focus should be the impacts or error of the results if something is not properly represented. This shift in thinking will allow the planner to assess and focus on those subrequirements which are important to the study results. R1.1.1 Planned outage duration needs to be defined. For example, a planned outage for a year or more should be included in the

Organization	Question 1 Comment
	Near term assessment.

Response: Requirement R7 (formerly Requirement R6) requires the Transmission Planner and Planning Coordinator to determine and identify joint responsibilities. The SDT believes that having this as a separate requirement is sufficient. No change made.

The SDT believes that the VSLs for Requirement R1 are already sufficient based on lack of industry comments. Note that the VSLs were modified to conform to the changes made to the requirement. Violation Risk Factors assess the impact to the BES of violating a requirement – not VSLs.

Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.

Organization	Question 1 Comment
Western Area Power Administration	General, all-encompassing comment: The change in TPL Standards, while well intended, will be difficult to administer since it has taken a simple Performance Table and translated it into a legal-type document that is very complex to relate to the physical system for the planning and operations staff. The performance requirements must be related to the physical response characteristics of the interconnected system operation without depending on a legal advise for training my new transmission system planning staff. The language in R1.1.2 needs to be clarified. Many of these facilities are not explicitly included in the models in the base cases (circuit breakers, protection system equipment, control devices). The language should be clarified to require modeling the effect of the devices or the effect of the removal of the devices where it is expected to impact the study outcome. Clarity is needed to explain the difference between R1.1.4 and R1.1.5. Expected interchange can be reasonably projected, but information on Firm Transmission Service is not always known or reasonably projected for future cases. For consistency with the 2nd bullet under R2.1.3, R1.1.4 should refer to expected transfers rather than Firm Transmission Service. With this change, R1.1.4 and R1.1.5 would be redundant and one should be deleted. I disagree with the inclusion of the words including requirements of regulatory authorities and other legal obligations at the end of R1. Entities already are required to do this. It does not need to be included in the standard.

Response: The SDT believes that it is following the intent of FERC and NERC in creating a reliable Bulk Electric System by following the requirements in TPL 001-1.

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is “the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption.” Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

1.1.5 Known commitments for Firm Transmission Service and Interchange

The SDT has removed “including requirements of regulatory authorities and other legal obligations” since utilities already have to abide by such requirements.

Organization	Question 1 Comment
R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	
Ameren	There may be a potential conflict between MOD-010 and MOD-012 and legal documents such as Interconnection Agreements e.g. IA may specify a capacity level that exceeds the reported test levels. In the case of such conflicts, it is not clear which one should rule. Suggest replacing circuit breakers in R1.1.2 with terminal equipment since circuit breakers are covered by Protection System Equipment. Consider adding a reference in R1 to NERC Reliability Assessment Guidebook version 1.2, pp 17-18 for use of a particular load forecast level for inclusion in the planning models. I n R1.1.2, revise the language to show that we need to also represent the existing transmission system, and not just changes to the existing system. In R1.1.2, Clarification is needed for the phrase for each year should signify only those years for which assessment work was performed, rather than each year of the Near-Term and Long-Term Transmission Planning Horizon. There typically is not a model built for each year of the Near-Term and Long-Term Transmission Planning Horizon. In bullet three of R1.1.2, it is not clear whether bus-tie circuit breakers to be represented in the models. Typically circuit breakers are included in the contingency definitions along with the protection system equipment used in the powerflow models. The number of zero impedance branches which can presently be modeled using PSS/E software is limited to 4000. Also, the number of buses included in the powerflow models would increase with additional breaker modeling. In bullet seven of Requirement R1.1.2, what "new technologies" are to be represented in the models” R1.1.4 Firm Transmission Service - a single source can have transmission service to multiple sinks, and can be associated with transmission service in excess of the capacity of the source. There is a lack of clarity regarding the means by which Firm Transmission Service, a marketing term, is to be included in planning models. For example, should the standard define how to model wind farms (100% - off-peak and 20% on-peak, based on firm capacity from the wind generators, or other dispatch levels)?

Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes.

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The SDT does not believe that a reference is needed to the NERC Reliability Assessment Guidebook since most utilities are using at least a 50/50 Load forecast as a minimum. No change made.

Organization	Question 1 Comment
The SDT has revised Requirement R1, part 1.1.1 to include "existing Facilities". **1.1.1** Existing Facilities The SDT has deleted the reference to year. **1.1.3** New planned Facilities and changes to existing Facilities See response to Requirement R1, part 1.1.2 above. . New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the list in Requirement R1, part 1.1.2 (now part 1.1.3) and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that all firm Transmission contracts should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
Puget Sound Energy, Inc.	The language in R1.1.2 needs to be clarified. Many of these facilities are not explicitly included in the models in the base cases (circuit breakers, protection system equipment, control devices). The language should be clarified to require modeling the effect of the devices or the effect of the removal of the devices where it is expected to impact the study outcome. Clarity is needed to explain the difference between R1.1.4 and R1.1.5. Expected interchange can be reasonably projected, but information on Firm Transmission Service is not always known or reasonably projected for future cases. For consistency with the 2nd bullet under R2.1.3, R1.1.4 should refer to expected transfers rather than Firm Transmission Service. With this change, R1.1.4 and R1.1.5 would be redundant and one should be deleted.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
Tenaska, Inc.	It is not clear that Requirement R1 requires ALL existing generators, substations, transmission line, transformers, etc. to be explicitly modeled for steady state and stability studies. In fact, Requirement 1.1.6 could be interpreted to exclude various generators from the models if they are not contracted to supply load. A suggestion is to re-word R1.1 to read as follows:R1.1 Models for the Planning Assessment shall represent all existing generators, substations (including specific busses within a substation), transmission lines, loads, capacitors, reactors, and other equipment connected to the transmission system and shall

Organization	Question 1 Comment
	further represent the following:(continue with R1.1.1 through R1.1.6) A further refinement to R1.1.6 should also be considered as follows:R1.1.6 Committment and dispatch schedules of resources expected to serve Load for the specific model.
Response: The intent of the SDT is to model all bulk electric Transmission Facilities depending on the model used - whether for load flow, Stability, or short circuit. The SDT has modified Requirement R1, part 1.1 to provide better clarity on these models. **1.1** System models shall represent: Requirement R1, part 1.1.6 has been broadened while still incorporating Network Resources. **1.1.6** Resources required to supply Load	
Manitoba Hydro	Requirement Text: R1: What is meant by including requirements of regulatory authorities and other legal obligations? This phase should be deleted. Can NERC make it an obligation in a standard to follow regulatory authority and other legal obligations? The planner has scope to determine the projected system conditions, and if a local regulator mandated a requirement, the planner would be able to include it without this statement. R1.1.1: Only long duration known planned or scheduled outages that are expected to last over a system peak should be included in the scope of this standard. Known planned or scheduled maintenance outages should not be a part of the planning scope as they are short duration and are planned to be taken when system conditions allow. Suggest wording change to Planned outages of generation and Transmission Facilities with an expected duration of 6 months or longer, if specifically known. R1.1.2: Suggest deleting new technologies as it is unknown as to what this is. If the SDT wants to make the list all inclusive, add words such as shall include but not be limited to in the requirement wording. Circuit breakers are not specifically represented in the planning models in order to keep the number of buses within the program capabilities. However, the effect of the circuit breaker configuration is normally considered in the creation of contingency files. Can the drafting team confirm that circuit breakers do not have to be specifically represented in the model? The same comment can be said about protection system equipment. Some generic zone 1 modeling may be included but in general the effect of protection equipment is included in contingency files. R1.1.4 & R1.1.5: Firm Transmission Service represents a contract that the planner is obligated to include. Based on the NERC definition, Interchange is defined as Energy transfers that cross Balancing Authority boundaries. Including it as a requirement mandates system expansion for non-firm system usage. Interchange is already covered in the sensitivities (Expected Transfers) and should not be a specific sub requirement of R1.1.2. Perhaps simply documenting the value of the Interchange used in the Model is sufficient. This value may change in the sensitivity analysis conducted in R2.1.3 and the TP/PA will decide the level that they will plan on protecting.Measure: The measure requires the planner to provide evidence such as the System model. What further evidence is required to ensure the planner is using data consistent with the MOD standards, is simulating projected system conditions, and that the models represent the required information in accordance with Requirement R1? It is suggested to remove and shall simulate projected System conditions from the main paragraph of R1 and reword R1.1 to System models and contingency files for the Planning Assessment shall represent projected System Conditions including:

Organization	Question 1 Comment
	Requirement R1 is very vague, and the Measure refers back to R1. The MOD standards deal with the building of the model. Most planners provide data in accordance with the MOD standards for a regional model building process. These models form the basis for the models the TPs and the PC use. The R1could be more specific by requiring the PC/TP to provide rationale for the projected system conditions used, which might include the generation schedule assumed, the transfer conditions, why peak or off-peak is important, etc.. VSLs: The requirement is very generic in nature and leans on the MOD requirements. Verification of compliance to this requirement will be problematic. What will be required to prove that the data "is consistent with the data provided in accordance with the MOD-010 and MOD-012 and other data sources"? What are these other data sources?? R1 only stipulates that the planner shall "simulate expected system conditions", so how does one decided that the "model did not simulate projected System Conditions as described in R1" (severe VSL)?

Response: The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months**.**

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months

New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the equipment list in Requirement R1.1.2 since these are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.

Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

1.1.5 Known commitments for Firm Transmission Service and Interchange

Requirement R1 has been revised to replace "simulate" with "represent".

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System

Organization	Question 1 Comment

conditions.

The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has incorporated these additional requirements with the intent that they will be removed from the TPL standard when they are incorporated into the MOD standards at a later date.

The SDT has removed "and other date sources" from Requirement R1.

The SDT has replaced "simulate" with "represent" under the Severe VSL category for Requirement R1.

R1 VSL	The responsible entity's System model failed to represent one of the Requirement R1, parts 1.1.1 through 1.1.6	The responsible entity's System model failed to represent two of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not use the latest data consistent with the data provided in accordance with the MOD-010 and MOD-012 standards and other sources, including items represented in the Corrective Action Plan.	The responsible entity's System model failed to represent three of the Requirement R1, parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not represent projected System conditions as described in Requirement R1.

Organization	Question 1 Comment
E.ON U.S.	R1.Delete and other data sources. Consistency with MOD-010 and MOD-012 standards is measurable and should suffice. Delete including requirements of regulatory authorities and other legal obligations. The term: shall simulate projected System conditions does not exclude the above. If there is some significance to this statement it should be an item in R1.1. R1.1.4.Firm Transmission Service is often sold for less than one year on an as available basis. Also, Firm Transmission Service may be sold on one system without a complete path. As stated, it appears necessary to include these examples in the Planning models. E.ON U.S. believes that there should be some limitations put on this requirement such as Long-Term Firm Transmission Service for a period of 5 or more years.

Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has removed "and other data sources".

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System

Organization	Question 1 Comment
conditions. The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
National Grid	Comments: R1: A. Priority Comment- There needs to be some direction provided on the initial conditions used in the assessment. This guidance should encourage the use of initial conditions that reasonably stress transfers across interfaces between companies, areas, regions, into load pockets, and out of constrained areas. The expectation that transfers are reasonably stressed for a variety of interface conditions will require the consideration of different generation dispatches, which goes beyond the single generator out of service requirement of the standard. If initial conditions consider reasonably stressed conditions, then sensitivity analysis is embedded in the process. If sensitivity is embedded in the process, it is unclear if additional sensitivity is still required by the standard. B. In the reference to regulatory authorities and other legal obligations it is suggested that the phrase be changed from "simulate projected System conditions including requirements of regulatory authorities and other legal obligations" to "include projected System conditions and requirements of regulatory authorities and other legal obligation." In common usage of terms, models are used to simulate system response, but models alone do not simulate the system. Violation Severity Levels:R1 Suggest changing the phrase "simulate projected System conditions as described in Requirement R1" to "include projected System as described in Requirement R1," consistent with the recommended change to Requirement R1. Errata:Delete the period after "R1" in the first bullet in the Data Retention section. R1.1.1 Priority comment ? R1.1.1 should be removed. - Planned outages are addressed by Operational Planning processes and Transmission Operating Procedures for up to two years ahead removing the need for this to be incorporated into Planning Assessments. - If outages are planned, but Operations can not accommodate them in real time, then the outages are cancelled. - Outages are not generally known beyond one to two years in advance. R1.1.2 Comment - We recommend deleting the list of facilities:- Circuit breakers are not modeled as elements in a power flow nor are Control Devices and Protection Systems - The list of facilities is not consistent with the definition of "Facilities" in the NERC GlossaryR1.1.2 should simply read:R1.1.2New planned Facilities and changes to existing Facilities for each year of the Near-Term and Long-Term Transmission Planning Horizon. R1.1.3 Comment - The use of "real and reactive power" is prevalent within the industry, but R1.1.3 should be changed to "Active and reactive Demand of Load." When load is expressed as a complex quantity, active power is the real portion and reactive power is the imaginary portion. Thus for consistency, we should refer to active and reactive. R1.1.5 Comment What specifically needs to be modeled under Interchange" R1.1.6 Comment "This needs further definition or it should be deleted. It is not clear what a "network resource required to supply

Organization	Question 1 Comment
	load" is. Does this refer to Network Resource per FERC LGIP?

Response: Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. However the expected transfers under Requirement R2, part 2.1.3 are to further stress the system as a possible sensitivity analysis.

1.1.5 Known commitments for Firm Transmission Service and Interchange

The SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The SDT has replaced "simulate" with "represent" under the Severe VSL category for Requirement R1.

R1 VSL	The responsible entity's System model failed to represent one of the Requirement R1, parts 1.1.1 through 1.1.6	The responsible entity's System model failed to represent two of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not use the latest data consistent with the data provided in accordance with the MOD-010 and MOD-012 standards and other sources, including items represented in the Corrective Action Plan.	The responsible entity's System model failed to represent three of the Requirement R1, parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, parts 1.1.1 through 1.1.6. OR The System model did not represent projected System conditions as described in Requirement R1.

The SDT agrees and had made this change under Data Retention.

Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.

The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in

Organization	Question 1 Comment
MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT has modified Requirement R1, part 1.1.4 (former part 1.1.3). **1.1.4** Real and reactive Load forecasts Interchange is defined in the NERC glossary as "energy transfers that cross Balancing Authority boundaries" while Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." The intent is to include, but not be limited to these requirements. The SDT has revised Requirement R1, part 1.1.6. **1.1.6** Resources required to supply Load	
Entergy Services, Inc	Planned facilities and planned changes to existing facilities should be further defined to ensure facilities or changes that are unlikely to be constructed are not included in the models. See the proposed definition of planned facilities in the comments provided to question #8. Facilities included in the models should be only those projects that are committed to by the Transmission Owner or other users of the transmission grid. Consistent with the standards requirement to include only firm transmission service (R1.1.4), uncommitted facilites should not be included because an oversubscription of the grid could occur. R1.1: Please clarify what the SDT means by models for the Planning Assessment shall present, expecially for facilities such as circuit breakers, protection system equipment, and new technologies. Models also need to represent existing facilities R1.1.2: The phrase, for each year of the Near-Term and Long-Term Transmission Planning Horizon, should be revised to remove each year because there may not be studies in each year. R1.1.4: Firm Transmission Service - a single source can have transmission service to multiple sinks, and can be associated with transmission service in excess of the capacity of the source. There is a lack of clarity regarding the means by which Firm Transmission Service, a marketing term, is to be included in planning models. Not sure if this is applicable to Requirement 1 or 2.
Response: The projects that get included under the Corrective Action Plans are presumed to be the utility's best alternatives at that time in order to achieve compliance. The SDT understands that these alternatives may change over time - but these changes must be addressed under Requirement R2, part 2.7.6 in the revised standard. The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement r2, part 2.7.1 in the revised standard. The reference to year has been deleted. The SDT believes that all firm Transmission contracts should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.	

Organization	Question 1 Comment
1.1.5 Known commitments for Firm Transmission Service and Interchange	
Great River Energy	R1.1 is just repeating what should already be in the MOD-010 and MOD-012 requirements. Why re-iterate this in the TPL standard? The planners are expecting that the model building process will already include these components listed in R1.1 otherwise there wouldn't be a functional model. R1.1.1 may be the only thing that needs to be identified in R1 as any known long-term outage or retirement of a facility may have happened after the model building process. If R1.1 is kept I would suggest removing "Models for" so that R1.1 reads "The Planning Assessment shall represent: R 1.1.1 says the assessment shall represent planned outages if specifically known. It does not however distinguish the length of the outage to be considered. Should a 1 week maintenance outage in Year five be included? Should a 2 year complete rebuild outage lasting through year two and three be included? It is GRE's opinion that the SDT needs to add a comment about the length of the planned outage and its relevance to the assessment. In the Violation Severity Levels, R1 seems to be weak since any solved model should meet this requirement. Again this would seem to be more related to the MOD010 and MOD012 process. R1 should focus on documenting changes that are being preformed against the data that was submitted in MOD-010 and MOD-012 process.
Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has incorporated these additional requirements with the intent that they will be removed from the TPL standard when they are incorporated into the MOD standards at a later date. The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT has revised the language in Requirement R1, part 1.1 (now part 1.1.2) based on industry comments. . **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. The SDT believes that the Severe level should be applied as noted in the VSL table since these cases are the basis for having an accurate Planning Assessment. No change made.	
BC Hydro	Comments: Consider just referring to the MOD series of standards, not specific individual MOD standards because the numbering of the MOD standards could change and additional relevant MOD standards could be added. Consider rewording the second sentence to read, The data and models shall meet all requirements of the MOD series of standards. The MOD standards should include the requirements of regulatory authorities and other legal obligations and need not be repeated in the TBL standard(s). R1.1.2: Consider changing to, New planned Facilities and planned changes to existing and changing the fifth bullet to read, Normal actions of Protection System equipment R1.1.3: Consider changing to, "End-use customer loads and generators [how small loads are aggregated should be covered in the MOD standards. A key point is that large industrial customers with significant generation that reduces their net peak demand should not be represented simply as a net load since that would not properly model the dynamic impacts of the load and

Organization	Question 1 Comment
	generation components]. R1.1.4: Consider changing to, Worst-case transfers on Firm Transmission Service Reservations. R1.1.5: Consider removing this requirement. It should be covered by R1.1.4 R1.1.6: Consider changing to, Generating units [the MOD standards should specify the details like how exciters, governors and associated control equipment must be modeled] Comment on M1: Consider changing to, using data consistent with the MOD series of standards, simulating. Consider just referring to the entire series of a particular standard, not specific individual standards because the numbering of the standards being referenced could change and additional relevant individual standards could be added.

Response: The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT referenced the specific MOD standards to ensure that the requirements were limited to those needed to complete the Planning Assessment. When the MOD standards are revised, this standard will be reviewed for conforming changes. The SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements.

R1 Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The SDT has reworded Requirement R1, part 1.1.1 to include existing Facilities.

1.1.1 Existing Facilities

The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part R3.3, Requirement r4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

The SDT has modified Requirement R1, part 1.1.4 (now part 1.1.5) to state "Real and reactive Load Forecasts. Note that the generator modeling is addressed in the MOD standards.

1.1.4 Real and reactive Load forecasts

The SDT believes that all contracted firm Transmission should be modeled. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.

1.1.5 Known commitments for Firm Transmission Service and Interchange

See response for Requirement R1, part 1.1.2 above.

The SDT believes that the specific MOD standards should be addressed in this TPL 001-1 draft since they deal directly with the modeling requirements necessary for creating base cases. No change made.

Organization	Question 1 Comment
Midwest ISO	Generally the Midwest ISO agrees with FirstEnergy's comments regarding this requirement. However, if the SDT insists on keeping this requirement as is then we propose the following corrections specific to each requirement. Specific Comments for Requirement 1: A) Under R1 there is language that references "other data sources; can the SDT please offer some clarification on what "other data sources are to be Could other data sources be Tariff requirements" B) Again under R1, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R1 only says "Long-term Planning". By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: Near-Term and Long-Term Transmission Planning. C) Under R1.1.1 it is required that models represent planned outages of generation and transmission facilities, if specifically known. This does not allow or require a Transmission Planner or Planning Coordinator to include outages due to maintenance and/or due to construction programs where certain facilities are out of service during various phases of construction, as part of the Assessment. For this reason, we believe the following language for R1.1.1 would improve this requirement: Planned outages of generation and Transmission Facilities if specifically scheduled or planned for. D) Under R1.1.1 we suggest adding sub-requirement R1.1.7 Generation dispatch patterns deemed appropriate by the Transmission Planner and Planning Coordinator. This clarifies that when building System models, generation dispatch is part of the model building process. E) Under R1.1.2 there is uncertainty around the language of New planned Facilities. We offer the following definition for Planned Facilities to be added to the definition section of this standard and further added to the NERC Glossary of Terms: Planned Facilities Generation and Transmission Facilities that are expected to be implemented with an in service date prior to the plan year being studied. F) Under R1.1.2 a bullet should be added for Relay Loadability Limitations. The standard requirements for relay loadability are included in PRC-023-1.

Response: The SDT has removed the language "and other data sources".

> **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.

The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. No change made. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.

Organization	Question 1 Comment
• **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal. • **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time. • **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system. • **Operations Assessment** — follow-up evaluations and reporting of real time operations. If a transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-contingency. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months. **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. Requirement R1, part 1.1.6 now states Resources required to supply Load. **1.1.6** Resources required to supply Load Requirement R1, part 1.1.3 covers new planned Facilities and changes to existing Facilities. **1.1.3** New planned Facilities and changes to existing Facilities The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7. Relay loadability is covered under Requirement R3, part 3.3.3. No change made.	
PJM	In R1, why require a Planning Coordinator AND a Transmission Planner to maintain models for the same area Concern with the words - for each yearin R1.1.2. Does this mean that a case for each year, at least, will need to be produced? Will five, one for each season and a light load, each year need to be produced R1.1.5 is not clear. Is the Interchange exclusive of Firm Transmission Service as mentioned in R1.1.4 Maybe -non-firm transmission service-- is clearer.
Response: Requirement R7 requires the Transmission Planner and Planning Coordinator to determine and identify joint responsibilities. The SDT has modified Requirement R1 to state that the Transmission Planner and Planning Coordinator are responsible for maintaining System models for their respective areas. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within their respective areas for performing the studies needed to complete their Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The SDT has revised Requirement R1, part 1.1.2 (now part 1.1.3) to delete the reference to "year".	

Organization	Question 1 Comment
1.1.3 New planned Facilities and changes to existing Facilities The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
American Electric Power	Under R1.1.2. Add Transformers, otherwise, revise Transmission Lines to read Transmission Facilities. Also under R1.1.2., add Series Reactors and Capacitors as a distinct category of facilities from Reactive Power devices that include shunt capacitors and reactors, and Control devices that include phase angle regulating and variable frequency transformers, FACTS devices, and other power electronics. These additions would further clarify the types of facilities that should be included, and these comments are made in full recognition that the introductory sentence to R1.1.2. contains the wording such as.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7. The SDT has also revised this requirement to remove 'such as'.	
ITC Holdings	Comments: We question the value of R1.1.1, which requires the inclusion of transmission or generator outages if..known, in a planning standard. If an outage puts you in a compliance deficiency for the duration of any outage, would you be fined for such an instance? Category P6 contingencies should cover these outages and not require a separate requirement such as R1.1.1. This requirement could also make an entity subject to fines for long term outages needed to upgrade or replace equipment as part of a CAP for other category violations. If this requirement is kept, it should be restricted to very long term outages and exclude those outages needed to complete CAPs for other violations. R1.1.6 requires the use of Network Resources to supply load. For many planning studies, particularly beyond the five year window, the capacity additions needed to supply load are frequently unknown. Since there are no requirements or guidelines for assuming what and where these resources will be, assumptions will have to be made regarding the needed resources. Additionally, existing network resources could be retired or re-designated to serve other load. It is unclear as written exactly what would be a violation of this requirement if known network resources are not sufficient to serve projected load. Finally, with the advent of market power, would a dispatch utilizing this type of dispatch be considered a violation of this standard.
Response: The SDT believes that the outages should be modeled to insure the system reliability during the outage durations. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months. If a transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-contingency. All performance criteria would then apply to that new base case. **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.	

Organization	Question 1 Comment
The SDT has revised Requirement R1, part 1.1.6. to include Resources required to supply Load. **1.1.6** Resources required to supply Load	
Northern Indiana Public Service Company	Under R1.1, insert, "as applicable" after "represent". Since R1 covers steady state, short circuit and dynamic models, data requirements should be applicable to the specific model. Representation of circuits breakers, protection system equipment and control devices is not typical of steady state model inputs.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.	
Minnesota Power	A) Under R1 there is language that references other data sources; can the SDT please offer some clarification on what other data sources are to be? Could other data sources be Tariff requirements? B) Again under R1, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R1 only says Long-term Planning. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: Near-Term and Long-Term Transmission Planning. C) Under R1.1.1 it is required that models represent planned outages of generation and transmission facilities, if specifically known. However, the requirement does not distinguish the length of the outage to be considered. Should a one week maintenance outage in Year Five be included? Should a two-year complete rebuild outage lasting through the entire years 2 and 3 be included? The SDT team needs to add a comment about the length of the planned outage and its relevance to the assessment. D) R1.1 is repeating what should already be in the MOD-010 and MOD-012 requirements. Is the inclusion of these elements in the TPL standard redundant? The planners expect the model building process will already included the components listed in R1.1, otherwise there would not be a functional model. If R1.1 is kept, we suggest removing the “Models for” so that R1.1 reads “The Planning Assessment shall represent:”
Response: The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. The SDT has deleted the language “and other data sources”. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within their respective areas for performing the studies needed to complete their Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made.	

Organization	Question 1 Comment
Mitigation Time Horizon The time horizons available for mitigating a violation to a requirement include the following: • **Long-term Planning** — a planning horizon of one year or longer. • **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal. • **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time. • **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system. • **Operations Assessment** — follow-up evaluations and reporting of real time operations. The SDT believes that the outages should be modeled to insure the system reliability during the outage durations. If a transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-contingency. All performance criteria would then apply to that new base case. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months. **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has incorporated these additional requirements with the intent that they will be removed from the TPL standard when they are incorporated into the MOD standards at a later date. The SDT has reworded Requirement R1, part 1.1. **1.1** System models shall represent:	
LADWP	For R1.1.4 the requirements should be based on "expected transfer" instead of "firm transmission service". When projecting into future, the term "firm transmission service" is meaningless because transmission service contracts can be changed overnight. Using "firm transmission service" as a base would also exclude any new contract that are not considered in the study. It is very short-sighted to plan new transmssion facilities only based on "firmed transmission services". R1.1.2 is very confusing. What is a new technology? Is it something we don't know? If we know what it is, is it still a new tchnology? If we don't know, how do we model it? Also, we do not model individual circuit breaker but the effect of the circuit breakers; same apply with control devices or protective system equipment. Need more clarity. In general, a laundry list of items to be represented is a bad idea because it gives the impression that anything not on the list does not need to be modeled.
Response: The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is “the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption.” Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	

Organization	Question 1 Comment
New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.). New technologies were removed from the list in Requirement R1, part 1.1.2 and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.	
Platte River Power Authority	R1.1.2. "....for each year of the Near-Term and Long-Term..." Models for each year of the 10 years in the planning horizons are not developed in our Region. Please clarify your intention. R1.1.2. 3rd bullet - "Circuit breakers (or the effects of)" R1.1.2. 4th bullet - "Protection System equipment (or the effects of)" R1.1.2. 5th bullet - "Control devices (or the effects of)" R1.1.2. 6th bullet - "New techonologies (or the effects of)" R1.1.4. "Firm Transmission Service (or expected transfers)
Response: The SDT has deleted "year". **1.1.3** New planned Facilities and changes to existing Facilities The SDT has removed the equipment list under Requirement R1, part 1.1.2 (now part 1.1.3). Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange	
MAPPCOR	R1 - what it means to include requirements of regulatory authorities and other legal obligations. Even if some version of this language is kept in the final standard, it seems to belong in R2 rather than R1. R1.1.1 - should remove the word specifically since it means nothing. Only known long-term outages of generation and transmission should be required to be modeled. R1.1.2 in the first line should have the word studied to avoid confusion, to read "New planned Facilities and changes to existing Facilities for each year studied of the "?

Organization	Question 1 Comment
	R1 states that the models used in these studies shall be consistent with data provided through MOD-010 and MOD-012. The data submitted for these are updated on a schedule provided by the RRO and not necessarily reflective of any emerging changes that may have occurred between the MOD data collection cycle. The requirement should allow for exceptions to allow the most recent information to be included in the TPL studies.
Response: : The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within their respective areas for performing the studies needed to complete their Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The SDT has deleted 'if specifically known'. **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. The SDT has deleted "year". The SDT has modified Measure M1 to use the latest data available. **M1** Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models, using the latest data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.	
Idaho Power	The language in R1.1.2 needs to be clarified. Many of these facilities are not explicitly included in the models in the base cases (circuit breakers, protection system equipment, control devices). The language should be clarified to require modeling the effect of the devices or the effect of the removal of the devices where it is expected to impact the study outcome. Clarity is needed to explain the difference between R1.1.4 and R1.1.5. Expected interchange can be reasonably projected, but information on Firm Transmission Service is not always known or reasonably projected for future cases. For consistency with the 2nd bullet under R2.1.3, R1.1.4 should refer to expected transfers rather than Firm Transmission Service. With this change, R1.1.4 and R1.1.5 would be redundant and one should be deleted.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement r3, part 3.3, Requirement r4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange.	

Organization	Question 1 Comment
1.1.5 Known commitments for Firm Transmission Service and Interchange	
Turlock Irrigation District	TPL 001-1 R1 could potentially result in a WECC auditor having to determine compliance with requirements of regulatory authorities and other legal obligations, beyond the scope of its expertise. TID proposes that if that language is to be retained, it shall be assumed that the requirements of regulatory authorities and other legal obligations are being simulated unless those other entities have formally found the member to be in violation of their requirements or obligations.
Response: The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed “including requirements of regulatory authorities and other legal obligations” since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	
New York Independent System Operator	R1.1.1 requires that models shall represent planned outages of generation and transmission facilities, if specifically known. The standard should be clarified to state whether it allows or requires a PC/TP to include as part of the Assessment outages due to maintenance and due to construction programs where certain facilities are out of service during phases of construction. Such maintenance and construction schedules are established but may not be finalized over the planning horizon. Further, the standard is not clear whether planned outages are to be treated as creating a normal system condition or as a contingency from which system adjustments are made prior to subsequent eventsMOD 10 and 12 are based on requirements determined by the RRO in MOD 11 and 13 respectively. Is this appropriate? Further, the PC is not an applicable entity in MOD 10 and 12. Moreover, the standard should define other data sources. R1.1.2. states that models for facilities such as circuit breakers and protection systems should be represented. Comment - The list of facilities should be deleted for the following reasons:- it is not needed;- the NYISO does not model circuit breakers, Control Devices, and Protection Systems;- it is not consistent with the definition of Facilities in the NERC Glossary.
Response: The SDT believes that the outages should be modeled to insure the System reliability during the outage durations. If a Transmission element outage occurs during a specified time, then the new base case for that time period would result with that element out of service pre-contingency. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months. **1.1.2** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. The Planning Coordinator is to still use the information provided under MOD-010 and -012. The SDT has removed “and other data sources”. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to	

Organization	Question 1 Comment
complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.	
Duke Energy	Revise R1.1.2 to include the phrase to be studied as follows: New planned Facilities and changes to existing Facilities for each year to be studied of the Near-Term and Long-Term Transmission Planning Horizon, such as :
Response: The SDT has deleted "year". **1.1.3** New planned Facilities and changes to existing Facilities Existing Facilities are now shown under Requirement R1, part 1.1.1. **1.1.1** Existing Facilities	
Tucson Electric Power Company	The language in R1.1.2 needs to be clarified. Many of these facilities are not explicitly included in the models in the base cases (circuit breakers, protection system equipment, control devices). The language should be clarified to require modeling the effect of the devices or the effect of the removal of the devices where it is expected to impact the study outcome. An alternative, instead of specifically listing elements, make a general statement that the models should include those elements required in MOD-010 through MOD-013. If an element is missing, double jeopardy could result due to a violation of the applicable MOD standard and this TPL standard. Clarity is needed to explain the difference between R1.1.4 and R1.1.5. Expected interchange can be reasonably projected, but information on Firm Transmission Service is not always known or reasonably projected for future cases. For consistency with the 2nd bullet under R2.1.3, R1.1.4 should refer to expected transfers rather than Firm Transmission Service. With this change, R1.1.4 and R1.1.5 would be redundant and one should be deleted. We disagree with the inclusion of the words including requirements of regulatory authorities and other legal obligations at the end of R1. Entities already are required to do this. It does not need to be included in the standard.
Response: The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. The SDT believes that additional modeling requirements not presently contained in the MOD standards are necessary for Transmission Planning purposes. The SDT has incorporated these additional requirements with the intent that they will be removed from the TPL standard when they are incorporated into the MOD standards at a later date.	

Organization	Question 1 Comment
The SDT believes that transfers and Firm Transmission Service are actually two separate items since Firm Transmission Service is "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	
Independent Electricity System Operator	1. R1: What modeling/simulation is envisaged by the phrase requirements of regulatory authorities and other legal obligations? Note that this condition is not included in the measure or the VSL, making its compliance (whatever it is) irrelevant. If it is indeed a needed condition, then it should be measured and included in the VSL language under the Severe condition. Further, we suggest replacing simulate with incorporate since R1 deals with building of the system model that will be used to perform simulations governed by Requirement R2. Moreover, we do not think this requirement (to simulate projected System conditions including requirements of regulatory authorities and other legal obligations) belongs to R1, which is a requirement to develop the system model. R2 is the requirement for conducting Planning Assessments which include simulation using the model. We suggest moving this requirement to R2 upon making appropriate changes, where necessary to address our comments on the wording. 2. We recommend introducing applicable before regulatory authorities. 3. R1.1.2: suggest to add Transformers. 4. R1.1.5: suggest to change Interchange to Interchange Schedules or Interchange Transactions. 5. We agree with the VRF, Time Horizon, Measures and VSLs, other than the requirements of regulatory authorities and other legal obligations noted above.
Response: The goal is for the responsible entity to build a realistic simulation, and the entity has to comply not only with the criteria in the TPL standard's tables, but also with other non-NERC regulations. However, the SDT has removed "including requirements of regulatory authorities and other legal obligations" since utilities already have to abide by such requirements. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions.	

Organization	Question 1 Comment
The SDT has changed the word "simulate" to "represent" in Requirement R1. The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note 'c' in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard. Requirement R1, part 1.1.5 has been revised to include known commitments for Firm Transmission Service and Interchange. **1.1.5** Known commitments for Firm Transmission Service and Interchange Thank you for your response on VRF et al.	
Kansas City Power & Light	R1 states that the models used in these studies shall be consistent with data provided through MOD-010 and MOD-012. The data submitted for these are updated on a schedule provided by the RRO and not necessarily reflective of any emerging changes that may have occurred between the MOD data collection cycle. The requirement should allow for exceptions to allow the most recent information to be included in the TPL studies.
Response: The SDT has modified Measure M1 to use the latest data available. **M1** Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models, using the latest data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.	
ReliabilityFirst Corporation	R1.1.1 requires to include Planned outages of generation and Transmission Facilities, "if specifically known" Should the generation be capitalized? Suggest changing it to "All planned Generation and Transmission facilities should be modeled. R1.1.2 Use of the word "such as" is not very clear and may not be enforceable. There are some size limitations in the study tools and it may not be possible to model all circuit breakers. Last three bullets are very hard to model and these are not consistent with MOD-010 and MOD-012. I am not sure what "New Technologies" mean. Does this require a model for each year? This contradicts the requirements in Sections R2.1-R2.1.1, R2.1.2 and R2.2. Suggest changing this to read "New planned Facilities and changes to existing Facilities for Near-Term and Long-Term Transmission Planning Horizon as described in Sections R2.1-R2.1.1, R2.1.2 and R2.2." Modeling of Protection Systems, Control Systems requires new data collection effort and falls under Section 1600 of NERC Rules of Procedure. The list does not include Transformers.Suggest removing Protection System equipment and Control devices from the list and adding another sub-section which states "Models should reflect the limitations imposed by Protective Devices and Control systems characteristics. Define "New Technologies"

Organization	Question 1 Comment
	R1.1.3 Here it is better to include the Type of Forecast (50/50 or 90/10). A reference NERC Reliability Assessment Guidebook can be included here.

Response: Generation is not a defined term itself in the NERC glossary - thus it does not need to be capitalized in Requirement R1.1.1. Requirement R1, part 1.1.2 has been revised to include known outages of generation or Transmission Facilities with a minimum duration of 6 months.

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.

The SDT has revised R1.1.2 to remove "such as". The SDT has removed the equipment list under Requirement R1, part 1.1.2. Transmission lines, generators, and reactive power devices are already included in MOD standards. Circuit breakers, Protection System equipment, and control devices are not typically modeled - the impact of these devices are typically simulated and thus these are already included in Requirement R3, part 3.3, Requirement R4, part 4.3, and in header note ‘c’ in Table 1. New technologies were removed from the list and are already covered in the Corrective Action Plan under Requirement R2, part 2.7.1 in the revised standard.

New technologies include any technology that is not currently in use on the electric power System that helps improve efficiency (i.e., energy storage/production technologies, low sag conductors, solid state interrupters, etc.).

The SDT has deleted “year".

1.1.3 New planned Facilities and changes to existing Facilities

The SDT does not believe that a reference is needed to the NERC Reliability Assessment Guidebook since most utilities are using at least a 50/50 Load forecast as a minimum. No change made.

2. Requirement R2 — Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: The industry had many comments on Requirement R2 but for the most part, the questions were requesting clarification. The SDT has changed a number of the parts of this requirement with the major changes being: part 2.1.4 and part 2.4.3 on sensitivities, additional clarification on part 2.2 for the Long-Term Transmission Planning Horizon and the addition of a new part 2.7.2 on multiple sensitivity deficiencies. The full list of changes is:

Year One: The first year that a Planning Coordinator or a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the end of the current calendar year.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.

2.1.4 (previously 2.1.3) For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

2.1.5 (previously 2.1.4) When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

2.2 The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6:

2.2.1 A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4 The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part2.6. The following studies are required.

2.4.1 System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Load level, Load forecast, or dynamic model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

2.5 (new) The Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed generation additions or changes in that timeframe and be supported by current or past studies.

2.6.1 (previously 2.5.1) For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2 (previously 2.5.2) For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

2.7 (previously 2.6) For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7 (previously 2.6) bullet 2: Installation, modification, or removal of Protection Systems or Special Protection Systems

2.7.2 (new) Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.5 (previously 2.6.4) If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The

Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.6 (previously 2.6.5) Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8 (previously 2.7) For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.2 (previously 2.7.2) Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

2.9 (previously 2.8) The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

R2 VSL	The responsible entity failed to comply with Requirement R2, part 2.9 or Requirement R2, part 2.6.	The responsible entity failed to comply withRequirement R2, part 2.3 or part 2.8.	The responsible entity failed to comply with one of the following parts of Requirement R2: part 2.1, part 2.2, part 2.4, part 2.5, or part 2.7	The responsible entity failed to comply with two or more of thefollowing parts of Requirement R2: part 2.1, part 2.2, part 2.4, or part 2.7.

Organization	Question 2 Comment
Dominion - Electric Transmission	R2.1.3 - Dominion suggests that SDT needs to be more specific on which of thevariations to include. Also for the last bullet, the SDT needs to clarify the duration ortiming of planned transmission outages (in relation to Planning horizon). R2.4.1 - While we appreciate the intent of introducing induction motor modeling in simulations, this is a difficult proposal in actual practice. The question of how much of the load is comprised of induction motors and what is a reasonable/practical model has been around now for over twenty years yet is still not resolved satisfactorily. For example, we have heard several experts declare the CLOAD model is inadequate for study. NERC needs to take the lead in developing appropriate models for the widely used simulation software and a methodology for determining load composition prior to requiring induction Load modeling in dynamic simulation studies. Additionally, this requirement states that Aggregate System Load model is acceptable to represent the dynamic behavior of induction motor Loads. Our interpretation is that such aggregate models shall be inserted by the Planners at the time of study, over a specific study area as determined by TP, and these models are not to be represented in the interconnection-wide (i.e. ERAG/MMWG) dynamics base cases. If ERAG/MMWG dynamics base cases are populated with such aggregate load models, the dynamic simulation cases could become very difficult to solve, if not impossible. R2.8 - Dominion does not see any purpose in reporting largest consequential load loss. This is not easily calculated, and

Organization	Question 2 Comment
	would vary from year by year, season by season. R2.9 - Dominion requests further clarification. Is the intent of this requirement to develop criteria for maximum allowable non-consequential load loss prior to requiring a corrective action plan or to just calculate such a load loss where it is permitted in Table 1?

Response: Part 2.1.3 (now Part 2.1.4) has been revised to provide greater clarification. It is intended that the Planning Coordinator or the Transmission Planner will select the variation to include in the sensitivity studies.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

The last bullet in Part R2.1.3 (now Part 2.1.4) is intended to cover planned outages of Facilities in sensitivity studies if such planned outages are known at the time the planning studies are performed, for example, nuclear power plant refueling, generating unit maintenance, etc.

Part 2.4.1 is intended to allow the Planning Coordinator and Transmission Planner the discretion in the use of aggregated System Load models in Stability Studies, if specific models are not available. However, it does not dictate the methodology or the process on how the studies are to be done.

Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

Organization	Question 2 Comment
Northeast Power Coordinating Council	It is recommended to replace the phrase prepare with conduct and document in the first sentence.R2.1.1 Comment The requirement to evaluate year one or year two should be removed. This is not consistent with the time horizon

Organization	Question 2 Comment
	identified in R2. R2.1.3 Comment - The emphasis on sensitivity testing in the existing section appears misdirected and should be focused on reasonable risk. The assessment should have to include a discussion of reasonable risk. The sensitivity list can be used to select sensitivities to assess risk. Having a requirement to perform one sensitivity just to meet the requirement of the standard does not add value to the assessment. R2.1.4 With respect to spare equipment strategy; this requirement imposes severe testing requirements upon the system. However, there is no discussion on the generation dispatch or system transfers that are to be used for this portion of the assessment. The expectations for changes in system stresses need to be clear as part of the standard. Additionally, this section does not contemplate changing the acceptability of load loss. After experiencing a major contingency such as this, some change in the acceptability of load loss should be expected. The standard should consider allowing Non-Consequential load loss for P1 & P2 events. The standard needs to allow Non-Consequential load loss for P3 & P4 events. Remove the wording (such as a transformer). What constitutes "spare equipment strategy"? Would a strategy that involves out-of-merit dispatch or operational restrictions be considered a valid "spare equipment strategy". If a transformer is lost, could a reconfiguration of the transmission system constitute a valid "spare equipment strategy" R2.2 Comment We suggest replacing the phrase a current System peak Load study with a valid System peak Load study in the first sentence. The word current is confusing as some read the word current to mean today's rather than valid. R2.3 Comment Please provide guidance as to what year should be represented when performing short circuit studies. R2.4.1 Comment ? Change to read: "For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.5.1 Comment We suggest deleting this requirement, and incorporating it into R2.5.2. R2.5.2 Comment To incorporate R.2.5.1 into R2.5.2; please modify the section as follows: For steady state, short circuit, or Stability analysis the study shall be less than five calendar years old or less: the latest Transmission Planning Horizon System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. [A 20 MVA generator is fairly small in a 30,000 MW system and system concerns would already be addressed though the System Impact Study]" An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES determined to be material by the Planning Coordinator or Transmission Planner. R2.6 Priority Comment As written, this section undermines the value of the sensitivity testing. This section should require a corrective action plan to fix problems determined in sensitivity analysis if there is a reasonable risk of occurrence. We suggest making the standard read Provide documentation that explains the reasoning for the sensitivities considered and selected. R2.6 Comment At the end of the second sentence, the phrase in the tables is used. We suggest using more definitive

Organization	Question 2 Comment
	language such as in Table 1. R2.6.2 Comment The phrase Project Initiation Date needs to be defined. It is unclear if this is this the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase as well as an in-service date should be modified to read as well as a target in-service date. R2.6.3 Comment Plans can provide a target in-service year but not an actual in-service year. R2.6.4 Priority Comment There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year's assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient time to incorporate this into that year's assessment and develop corrective actions. R2.8 Comment Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. R2.9 Comment This requirement is unclear. Is this requirement asking for each transmission planner to list their criteria for non-consequential load loss, or is it asking how much non-consequential load loss was being relied upon in the assessment? We recommend that the requirement be modified to require documentation of the maximum amount of non-consequential load loss that was relied upon during the assessment. It is strongly recommended that the standard should consider not allow non-consequential load loss to resolve any violation arising from the planning events in Table 1. Therefore, this requirement would then be deleted. The use of System Off-Peak Load is too general. Is the intention to have the system minimum load used here? Because of the seasonal differences in equipment ratings, seasonal peak and off peak (minimum) loads should be analyzed.

Response: The SDT was not able to locate the word "prepare" in the first sentence of Part 2.1.1. However, Requirement R2 states, "Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, document results, and shall cover steady state analyses, short circuit analyses, and Stability analyses". The SDT assumes that the comment was meant for this sentence. The SDT does not think that replacing "prepare" with "conduct and document" would add clarity, since Requirement R2 includes the requirement to document assumptions and results. No change made.

The SDT disagrees that the requirement to evaluate Year One and year two is inconsistent with the Time Horizon in R2. The new definition defines Year One as the first year that the planner is responsible for assessing. No change made.

Part 2.1.3 (now Part 2.1.4) has been rewritten to clarify the intent of the requirement. The Planning Coordinator or Transmission Planner can include a discussion of risk in response to the new Part 2.7.2 on the actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary. No change made.

In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.4 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Actions such as out of

Organization	Question 2 Comment

merit dispatch, operational restrictions, System reconfiguration can be part of a Corrective Action Plan if the System cannot meet performance requirements without the Facility in service. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2 is intended to require a study performed in the current year, as opposed to studies performed in the past years. Part 2.2 has been revised to provide greater clarity.

> **2.2** The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6:

For Part 2.3 the decision on the year to be represented in the study is left to the discretion of the Planning Coordinator or Transmission Planner. Part 2.3 only requires it to be either a study that was performed during the current year or in the past. For example, this year is 2009 and a study performed in 2009 is a current study, the study can investigate the System in a future year, which is at the discretion of the Planning Coordinator or Transmission Planner performing the study. Part 2.3 has been revised to provide greater clarity.

> **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.4.1 was not changed as suggested because the intent of the last sentence is to allow the use of an aggregated System Load model as an appropriate Load representation. The suggested change could be read to mean that an aggregated System Load model would not appropriately represent the dynamic behavior of Loads. However, Part 2.4.1 has been revised to provide greater clarity.

> **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Parts 2.5 .1 and 2.5.2 (new Parts 2.6.1 and 2.6.2) were not combined. While the SDT appreciates the concern that a 20 MW generation addition can be small compared to a large System, a NERC standard needs to be clear as to the applicability. A requirement, which contains "determined to be material by the Planning Coordinator or Transmission Planner", is not clear. Therefore, changing from 20 MW to "material" will also have to require justification from the Planning Coordinator or Transmission Planner on what is "material". Material has been deleted from the requirement.

Part 2.6.2 and 2.6.3 have been removed.

Part 2.6 has been modified and included as new Part 2.7. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur in more than one sensitivity). Although not required, the standard does not preclude the Planning Coordinator or Transmission Planner to develop Corrective Action Plans for high risk scenarios. However, if the scenario is high risk, then it should have been included in the base assumptions in the assessment and the Corrective Action Plan would have been required. The end of the second sentence has been changed to refer to

Organization	Question 2 Comment
Table 1 as suggested. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Part 2.6.4 (now 2.7.5) allows the Planning Coordinator or Transmission Planner to address situations that are beyond its control by utilizing Non-Consequential Load Loss and/or curtailment of Firm Transmission Service, which are normally not permitted. Depending on the urgency of the need, the Corrective Action Plan may be developed outside the normal Assessment cycle at the discretion of the Planning Coordinator or Transmission Planner involved. No change made. Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1. The recommendation that “the standard should consider not allow non-consequential load loss to resolve any violation arising from the planning events in Table 1” will include also the multiple Contingencies, for which loss of Non-Consequential Load is allowed in the existing TPL Standards. While the sentiment is laudable, it may not be practical. No change made. The use of System Off-Peak Load is intended to be general to allow the Planning Coordinator or the Transmission Planner to use their best judgment suited to the study area, since the System must be able to meet performance requirements over all demand levels. The Planning Coordinator or Transmission Planner is not precluded from investigating more System conditions than are required in this standard. No change made.	
Transmission Planning	R2.1.4. COMMENT: For the analysis to reflect the contingencies in Table 1 (P0 through P7 plus Extreme Events) is excessive. R2.5.2. COMMENT: The 20 MW change listed in bullet items are extremely small to larger transmission systems and by themselves would be unlikely to change BES response. As drafted, requirement 2.5 may be interpreted to preclude the use of any previous study in which the base case is not identical to the current planning case. It is recommended 2.5.2 be rewritten as follows; For steady state, short circuit, or Stability analysis: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period that would impact the study area. R2.6.2. COMMENT: What is considered a project initiation date is it implying a construction start date, or the first time that it was identified as a mitigation plan? Additionally, R2.6.2 and R2.6.3 are not necessary because a Corrective Action Plan, by definition, includes an "associated timetable for implementation". Recommend deleting this requirement. R2.8. COMMENT: Why is this data collection a requirement? The effort required to determine this data is substantial and the value of this data is questionable. Recommend deleting this requirement. R2.9. COMMENT: Why is this data collection a requirement? The effort required to determine this data is substantial and

Organization	Question 2 Comment
	the value of this data is questionable. Recommend deleting this requirement.

Response: Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

While the SDT appreciates the concern, the proposed revision could be interpreted as removing the threshold for minimum change in generation. Part 2.5.2 has been revised as Part 2.6.2 to include an alternative threshold to be based on the study area's installed generation capacity.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

Organization	Question 2 Comment
SERC Engineering Committee Planning Standards Subcommittee	R2.1: In R2.1, change the reference to requirement R2.6 (at the end of the last line) to R2.5. R2.1.4: In Requirement R2.1.4, recommend that the requirement be revised as follows: "When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience the possible unavailability of the long lead time equipment. R2.4.1: In Requirement R2.4.1, it is suggested that it be reworded to the following: "System peak Load for one of the five years, including Load models which appropriately represents the dynamic behavior of Loads, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Organization	Question 2 Comment
	R2.5.1:With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would cause needless work to be performed on those plants or areas of the system where no changes are occurring. Recommend add the following to the end of R2.5.1: unless justification can be provided to demonstrate that the results of an older study are still valid. R2.6.2: In Requirement R2.6.2, what constitutes a "project initiation date," and how will it be used? Please clarify. R2.8: Please explain the reason why Requirement R2.8 is needed in the Assessment. Reporting the largest Consequential Load Loss does not impact reliability. R2.9: Please explain the reason why Requirement R2.9 is needed in the Assessment. Reporting the largest Non-Consequential Load Loss does not impact reliability.

Response: In the new version, Part.2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.4.1 has been revised to reflect your suggestion.

2.4.1 System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Part 2.5.1 has been revised and included as Part 2.6.1 to address your concerns.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning

Organization	Question 2 Comment
Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Modesto Irrigation District	On pages 6 and 7 under sections R2.1.3 and R2.4.3, I think the magnitude of the variations in the conditions asked for in the sensitivity cases, should be defined and not left to the analyst to decide. On page 8 under Section R2.5.2, examples of material changes for generation are given, but no examples for transmission changes. Shouldn't we include examples of material transmission changes, too Comments: Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES R2.8 and R2.9 load loss comment. We don't agree with R2.8 & R2.9. What reliability purpose is served by these requirements?
Response: The items in Parts R2.1.3 (now Part 2.1.4) and 2.4.3 are intended for use as guides. NERC Standards must allow room for discretion of the Planning Coordinator and/or Transmission Planner who are closer to the issues in their respective areas. In Part 2.5.2 the SDT removed the examples related to the generation changes and therefore have not added examples of transmission changes. Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. Part 2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. Parts 2.8 and R2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
OPUC	2. Requirement R2 Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.Comments: A: Short circuit of over-stressed breakers is already addressed in Table 1.Ex1: P2-3,4 (Internal Breaker Fault),Ex2: P4 (Stuck Breaker while attempting to clear a fault). B: In R2.1.4 Table 1, it is unclear how transformer contingency analysis can be aggregated or batched. It is also still unclear

Organization	Question 2 Comment
	whether corrective action plans are required solely to meet performance requirements for sensitivities.

Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. This is not the same as the examples cited. Part 2.3 has been revised to provide greater clarity.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.6 has been revised and included as Part 2.7 to state that Corrective Action Plans do not need to be developed solely to meet the performance requirements for a single sensitivity run. Part 2.7.2 has also been added to require that the Corrective Action Plan include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur is more than one sensitivity).

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.2 Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

Organization	Question 2 Comment
Bonneville Power Administration	Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault). R2.1.1: Peak load modeled for the near term planning horizon may not be Year one or year two. Therefore, R2.1.1 should be revised to say System peak load for one of the five years. Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer.

Organization	Question 2 Comment
	This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. We also recommend changing this from a separate sub-Requirement to one of the sensitivities to be considered under 2.1.3. We also believe that the statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement. The 20 MW threshold identified as material change for generation in R2.5 is too small. The limit should be raised or based on a percentage of the study area's installed generating capacity. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event? if it is documented? R2.9 should be deleted. It is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent, among other things, on the types of load being served. It very well may be a case by case situation.

Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. Part 2.3 has been revised to provide greater clarity.

> **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the near-term planning horizon: 1) A Year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled. 2) A Year one or Year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. Therefore, the SDT declines to make the change as suggested.

Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.5 has been revised and references to the 20 MW change have been deleted.

> **2.5** The Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed generation additions or changes in that timeframe and be supported by current or past studies.

Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees

Organization	Question 2 Comment
that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
MRO NERC Standards Review Subcommittee	MRO NSRS proposes the following comments for R2: Modify R2.6.2 to remove the obligation to include the project initiation date. The inclusion of this date would add unnecessary work that is not needed to assure adequate BES reliability In addition, it is not clear whether initiation refers to the commencement of engineering, design, construction, etc.Augment R2.6.5 to include annual verification of the continued validity of the Corrective Action Plan because the value of implementation status is dependent on the status of continued validity. MRO NSRS suggests this text: Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status . . . Augment R2.7.2 to include annual verification of the continued validity of the Corrective Action Plan because the value of implementation status is dependent on the status of continued validity. MRO NSRS suggests this text that is similar to R2.6.5: Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status. Remove R2.8. MRO NSRS does not know of any reason why the investigation and inclusion of the largest Consequential Load Loss caused by any P1 or any P2 events is needed to assure adequate BES reliability. In addition, all events involving Consequential Load Loss are studied, not just the largest load loss (see R3.3.1).
Response: In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Parts 2.6.5 and 2.7.2 have been revised and included as Parts 2.7.6 and 2.8.2 respectively to reflect your suggestion. **2.7.6** Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures. **2.8.2** Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status. Part 2.8 is intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed the requirement and agrees that as written, it was unclear. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	

Organization	Question 2 Comment
SERC Engineering Committee Dynamics Review Subcommittee (DRS)	1. R2.1.4 Loss of 2 transformers is itself a very severe contingency. However, when it is combined with R2.1.4 (spare equipment strategy) it can lead to a triple contingenecy which is unnecessarily severe and has an extremely low probability of occurrence. We recommend that the requirement be deleted from the standard. In the subrequirements of 2.1.3 and 2.4.3, the use of the word timing is unclear. Consider using in service date or schedule for. With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would cause needless work to be performed on those plants or areas of the system where no changes are occurring. Recommend add the following to the end of R2.5.1: unless justification can be provided to demonstrate that the results of an older study are still valid.

Response: Part 2.1.4 (now Part 2.1.5) is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Parts 2.1.3 (now Part 2.1.4) and 2.4.3 have been revised to reflect your suggestion.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

Organization	Question 2 Comment
2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance. • Load level, Load forecast, or dynamic model assumptions. • Expected transfers. • Expected in service dates of new or modified Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. Part 2.5.1 has been revised and included as Part 2.6.1 to address your concerns. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.	
SERC Engineering Committee Reliability Review Subcommittee (RRS)	The proposed standard not only raises the bar for system performance requirements, but also raises the bar for reporting and documentation. We need to employ almost as many librarians and technical writers as engineers to develop and keep track of the documentation. Engineers need to spend more time performing the studies and spend less time documenting studies keeping track of documentation for multiple years. R2 Instead of document results the requirement should be to summarize results. While results will be documented, the Planning Assessment should just include a summary. R2.1 What's the value in being able to use qualified past studies if you have to use annual current studies? Strike the words supplemented with and insert the word or. In R2.1, change the reference to requirement R2.6 (at the end of the last line) to R2.5. Do not understand the rationale for being so prescriptive in requiring specific years to be studied in R2.1.1. Why not allow the TP and/or PC to decide on the three years to be studied in the Near Term? In the subrequirements of R2.1.3 and R2.4.3, the use of the word "timing" is unclear. Consider using in service date or schedule for. " In R2.1.3, it is suggested that the studies be referred to as the "base studies" to avoid confusion with the sensitivity studies. Also suggest that another phrase be added at the end for clarity. The entire R2.1.3 would then be as follows: For each of the base studies described in Requirements R2.1.1 and R2.1.2, sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment. Sensitivity studies would include changes to:oIn Requirement R2.1.4, it is suggested that language be added to reflect the possible unavailability of the equipment, such as: When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead

Organization	Question 2 Comment
	time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience the possible unavailability of the long lead time equipment. How would adequate lead times be determined" In Requirement R2.1.4, recommend that the requirement be revised as follows: When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience the possible unavailability of the long lead time equipment. Since R2.3 short circuit analysis is a new raising the bar requirement, should the implementation plan for this be for 5 years like the other new requirements? R2.3 Insert the phrase "one year of after the word addressing. In Requirements R2.3 and R2.4, do we need a reference to Requirement R2.5 for the past studies" Further clarification is needed in R2.4.1 concerning load models that appropriately represent the dynamic behavior of loads. In Requirement R2.4.1, it is suggested that it be reworded to the following: System peak Load for one of the five years, including Load models which appropriately represents the dynamic behavior of Loads, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable. R2.4.1: It is not clear how much Load must have a dynamic model. Likely, it must still be proven that the analysis software can accommodate every load in the model having a load model that includes induction motor models. To help address this, revise Load to be Load that could impact the study area is acceptable. Is a NERC drafting team addressing these issues to determine an industry standard? Load models referenced in R2.4.1 should be confined to the consideration of transient stability study work. In Requirement R2.4.3, it is suggested that this sub-requirement be reworded to the following: For each of the base studies described in Requirements R2.4.1 and R2.4.2, sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the base studies shall be included in the Assessment. Sensitivity studies would include changes to: Regarding Requirement R2.6, it is suggested that the word "modeled" be added as follows: For Planning Events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed in subsequent assessments but the System modeled shall continue to meet the performance requirements in the tables. Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. The Corrective Action Plan shall: In bullet three of Requirement R2.6.1, would we allow automatic generation tripping for a single (P1) event if it is not consequential? It seems that tripping of generation should be restricted to P2 events 2 or 3 at a minimum. In bullet five of Requirement R2.6.1, is there a maximum duration that operating procedures can be used before a capital

Organization	Question 2 Comment
	project must be included (or completed) in the Corrective Action Plan? With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would cause needless work to be performed on those plants or areas of the system where no changes are occurring. Similar to the draft MOD-026-1 standard, this period should be 10 years. With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would cause needless work to be performed on those plants or areas of the system where no changes are occurring. Recommend add the following to the end of R2.5.1: unless justification can be provided to demonstrate that the results of an older study are still valid. R2.5.2 Suggest deleting the phrase Material generation changes could include: and the two accompanying bullets. A change of 20 MW on a large system may not always be material. In Posting #2, undervoltage load shed, underfrequency load shed, and Special Protection Schemes were considered to be Non-Consequential Load Loss. In R2.6.1, installation or modification of Protection Systems or Special Protection Systems are now allowed as part of the Corrective Action Plan. Should undervoltage and underfrequency load shed also be allowed in the Corrective Action Plan? In Requirement R2.6.2, what constitutes a "project initiation date," and how will it be used? Please clarify. Please explain the reason why Requirement R2.8 is needed in the Assessment and how does reporting the largest Consequential Load Loss impact reliability? Please explain the reason why Requirement R2.9 is needed in the Assessment and how does reporting the largest Non-Consequential Load Loss impact reliability? If contingencies occur inside one utility that affect facilities in another utility, which utility is responsible for running these studies during the annual assessments?? R2.8 and R2.9 should be deleted. We don't see a reliability-related need for these requirements. In R2.9, does the requirement require the maximum non-consequential load that can occur for contingencies in Table 1 or does it require just the maximum that a utility will allow on its system? Suggest clarifying permissible or perhaps using similar language as found in R2.8. R2.9: One cannot determine the maximum permissible Non-Consequential Load Loss for every Planning Event. First of all, this should not be a requirement, as it is, for those events that do not even cause Non-Consequential Load Loss. Secondly, to obtain the maximum permissible value, one would have to stress the system in some way until one of the performance requirements are violated. That is an unreasonable stipulation and cumbersome to perform such an analysis.

Response: Requirement R2 has been revised to reflect your suggestion.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning

Organization	Question 2 Comment

Assessment shall use current or past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.

In Part 2.1 it is envisioned that not all parts of the studies on which the Assessment is to be based can rely on past studies. For example, a study on year five performed during the past year may not be representative of year five in the current year. A past study can still be used if it can be demonstrated that the requirements for use of past studies are met. No change made.

In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the near-term planning horizon: 1) A Year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled. 2) A Year one or Year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. Therefore, the SDT declines to make the change as suggested.

Parts 2.1.3 (now Part 2.1.4) and R2.4.3 have been revised to clarify the word "timing".

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Load level, Load forecast, or dynamic model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

The SDT reviewed Part 2.1.3 and declined to use the term "base study" because "base study" may have different meanings in different parts of the continent, and

Organization	Question 2 Comment

the term, "studies described in Parts 2.1.1 and R2.1.2" should be sufficient to avoid confusion. No change made.

Part 2.1.4 (now Part 2.1.5) is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

The SDT does not feel that Part 2.3 raises the bar as entities should have been performing these studies all along. No change made.

The SDT declines to revise Part 2.3 to include short circuit analysis for one of the years in the Near-Term Transmission Planning Horizon because Part 2.3 only requires that a Planning Assessment be performed. Past studies can be used to support the Planning Assessment. No change made.

Parts 2.3 and 2.4 have been revised to include the reference to the requirements for use of past studies.

> **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.
>
> **2.4** The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part 2.6. The following studies are required:

Part 2.4.1 has been revised to reflect your suggestion. In addition, Requirement R2.4 concerns only "The Near-Term Transmission Planning Horizon portion of the Stability analysis". Part 2.4.1 is a sub-part of Part 2.4, and so should also carry the same limitation.

> **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

The SDT reviewed Part 2.4.3 and declined to use the term "base study" because "base study" may have different meanings in different parts of the continent, and the term, "studies described in Parts 2.4.1 and R2.4.2" should be sufficient to avoid confusion. No change made.

Part 2.6 has been revised and included as Part 2.7 to reflect your suggestion. The third bullet in Part 2.6.1 is intended to meet the requirements in Table 1. Generation tripping is allowed at the discretion of the Planning Coordinator or Transmission Planner for P1 Events as long as there is no loss of firm Non-Consequential Load. In addition, in the fifth bullet, the duration for use of an operating procedure is also at the discretion of the Planning Coordinator or Transmission Planner because it may not be feasible environmentally to implement Transmission reinforcements in some locations.

Part 2.5.1 has been revised and included as Part 2.6.1 to address your concerns, but the SDT disagrees that the timeframe should be changed to 10 years.

> **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided

Organization	Question 2 Comment
	to demonstrate that the results of an older study are still valid. Part 2.5 has been revised to reflect your suggestion. **2.5** The Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed generation additions or changes in that timeframe and be supported by current or past studies. Use of generation tripping not precluded within the Standard and the maximum duration for operating procedures in Corrective Action Plans is not addressed within the standard. UVLS and UFLS are not precluded in the Corrective Action Plan for those events where controlled load shedding is allowed. The Standard does not address the acceptability of the tools to be used for any Corrective Action Plan. In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1. If Contingencies occur inside one utility that affect facilities in another utility, the Planning Coordinator or Transmission Planner for the utility, whose system is impacted would be responsible for performing the annual Assessment for those contingencies known to cause the impact. A certain amount of coordination will need to occur between the utilities. The parties can then mutually agree upon a Corrective Action Plan.
FirstEnergy Corp	The standard provides prescriptive language in requirement R2.4.1 regarding dynamic stability load models but is silent on steady-state load modeling. Most transmission planners use a conservative approach of simulating constant power loads in the steady-state environment, but other steady-state load modeling assumptions such as constant impedance load and constant current load can be utilized. At a minimum, the standard should require the transmission planner to document its load modeling assumptions for steady-state simulations. To this end, we suggest a new sub-requirement R2.1.1 be placed ahead of the existing R2.1.1 that parallels R2.4.1 and indicates the TP should document its load modeling assumptions for steady-state simulations. Specific comments, Requirements of R2A. R2.1: The requirement incorrectly references R2.6 which should be a reference to R2.5. B. R2.1.1: We propose that the SDT adjust requirement R2.1.1 to annually require one current year Near-Term and one Long-Term study, with the Long-Term study required to alternate between year six and year ten every other assessment year. This would reduce the workload on the industry and cover the mid-point transition period between the Near-term and

Organization	Question 2 Comment
	Long-Term horizons that the standard team believes needs some attention. We find the requirement to perform two Near-Term studies and one Long-Term study each year overly burdensome, in light of the increased workload caused by sensitivity analysis for each steady-state and stability review that is required. FE believes that one current year study within each time period should suffice in being able to interpolate and extrapolate results to cover the entire assessment range; especially when supplemented with qualified past study results. C. We offer the following comments related to requirement R2.4.1: 1. In the last round of comments we made the following comment "This requirement should be separated into two requirements as it covers two distinct topics; a) peak load study for one of the near-term years and b) dynamic load modeling." The SDT responded "...This Requirement is to make you properly represent the dynamic behavior of Loads at high System Load levels." Apparently, the SDT did not agree with our recommendation to split the requirement as no change was made in this regard. Therefore, as written the standard in R2.4.2 (stability study of the Off-Peak Load level) seems to imply that the appropriate modeling of dynamic behavior of loads, including consideration of induction motor loads, is NOT required for the Off-Peak Load stability study. Please clarify or confirm this view of R2.4.2. 2. R2.4.1: We are still of the opinion that the word "appropriately" is vague and only serves to add confusion within this requirement. It's recommended that "appropriately" be struck from the requirement. 3. R2.4.1: In Draft 3, the SDT added text to this requirement that states "An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable" to clarify that a detailed dynamic Load model is not required at each bus. We understand this to mean that the model is not expected to try and replicate the dynamic behavior of individual end-user Load characteristics and that general approximations for a customer class(es) (residential, commercial or industrial) simulated at a given load bus is acceptable. 4. Based on our comments C.1 through C.3 we propose the following requirement language: R2.4.1. System peak Load for one of the five years.R2.4.2. System Off-Peak Load for on of the five years.R2.4.3. Load models used for stability analysis shall represent the dynamic behavior of Loads, including the behavior of induction motor Loads. The study shall document assumptions made for representing the dynamic behavior of Loads, based on the following load classes - residential, commercial and industrial. D. R2.5.2: For clarity and readability we propose to insert the word "that" between the words "and would" so the requirement reads "...intervening period and that would impact ...". E. R2.6.1: This requirement indicates that an entity's Corrective Action Plans list situations where Table 1 Performance Criteria are not met and the associated actions needed to achieve required System performance. What if the actions and plans associated with newly identified deficiencies (current year studies) are not yet fully known and require further analysis and a more detailed study of various options. Would it be acceptable for a TP to indicate that the planned solution is To Be Determined? This could be a likely scenario for a long-term planning horizon study which may identify a number of deficiencies which require more detailed analysis to determine the appropriate solution. F. R2.6.2: We believe this requirement is overly prescriptive in requiring a project initiate date. The standard should not question an entity's project management but stay focused on whether or not the Correct Action Plan was put in place in a timely fashion. We propose that the team strike from this requirement the reference to project initiation date and focus on

Organization	Question 2 Comment
	whether or not Corrective Action Plans were completed in a timely manner to ensure Table 1 Performance Criteria is met. Additionally, project initiation date is pertinent to a operating procedure solution that is allowed by the standard. R2.6.4: We support requirement R2.6.4 but suggest the word "prudent" be struck from the text of the requirement as it can be subjective and open for debate. G. R2.7: This requirement introduces additional Corrective Action Plan requirements beyond what is stated in R2.6. FE proposes that the SDT restructure the two requirements into a single requirement (and sub-requirements) focused on Corrective Action Plans. H. R2.8: Does this requirement apply to sensitivity simulations? If so, it has limited applications to only those sensitivity analyses that consider variations in load such as a higher forecast (90/10), or increased reactive load (sensitivity to poor power-factor loads), etc. The SDT should consider clarifying the intent of the requirement if each current year study as well as their corresponding sensitivity simulation model(s) is intended to have this information documented within the assessment report. I. R2.9: We ask the SDT to confirm or correct our understanding that the requirement is asking about a TPs criteria for maximum allowable non-consequential load drop and NOT the maximum non-consequential load shed required to meet performance criteria for a particular contingency evaluation. We agree with the stated Measures, VRF, Time-Horizon, Data Retention and VSL of requirement R2

Response: The language does not preclude the documentation of the steady state Load model used because steady state assumption of Load model is a degree of conservativeness. See header note b. No change made.

In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

As written, Requirements R2 and Part 2.1.1 provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment and to assess other years in addition to those identified in Part 2.1.1. So the suggestion to alternate between year six and year ten every other assessment is already allowed as written. No change made.

In Part 2.4.1 the SDT specifies the dynamic Load model representation for on peak because the System voltages are generally lower during on peak. The percentage of motor load, e.g., in air conditioners, could significantly increase reactive power requirements especially when they stall due to low System voltage and can therefore impact dynamic System performance on-peak. However, motor Load would likely not pose the same problem during off-peak as the System voltages are usually higher. So, in Part 2.4.2, it can be left to the discretion of the Planning Coordinator or Transmission Planner whether the dynamic motor Load would need to be represented per Part 2.4.1,

Part 2.5.2 has been modified and included as Part 2.6.2 and the “intervening period” language has been deleted.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the

Organization	Question 2 Comment
Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Part 2.6 has been modified and included as new Part 2.7. Part 2.6.1 requires a Corrective Action Plan be developed to enable the System performance requirements in Table 1 and Part 2.6 states that "revisions to the Corrective Action Plans are allowed in subsequent assessments but the System shall continue to meet the performance requirements in Table 1". This allows the Planning Coordinator or Transmission Planner to develop a Corrective Action Plan that can consist, for example, of a number of potential alternative solutions, and, the Corrective Action Plan can be revised as the study continues. 'Prudent' has been deleted in Part 2.6.4 (now Part 2.7.5). **2.7.5** If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service. Part 2.7: Short circuit duty Assessment has been revised for clarity and included as Part 2.8. **2.8** For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall: Parts 2.8 and R2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
IRC Standards Review Committee	(1) When a spare equipment strategy does not cover the long lead time unavailability as stated in 2.1.4, will the system be treated as normal system condition or as having a contingency from which system adjustments are to be made prior to subsequent events. (2) Under R2.5 ?Past Studies may be used to support the Planning Assessment if they meet the following requirements and the sub requirement R2.5.2 states that for SS, SC, or stability analysis; the PRESENT system model shall not include any material changes, such as ".Does this mean that past studies may be used to support planning assessments as long as there are no material changes to the present system model" If so, that would be an impossible scenario to recreate.
Response: In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the	

Organization	Question 2 Comment
performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.5.2 is intended to allow the use of past study if the System that is being modeled for Assessment today has not materially changed from the one modeled in the past study for the study area. While changes are expected to occur between planning cycles, not all changes have significant impacts on System performance. For example, if the load growth in an area has not changed significantly, there is no change in the Transmission System and no addition of new generation, and then a case can be made that the past study can be used to support a new Assessment.	
TVA System Planning	Do not understand the rationale for being so prescriptive in requiring specific years to be studied in R2.1.1. Why not allow the TP and/or PC to decide on the three years to be studied in the Near Term? Since R2.3 short circuit analysis is a new raising the bar requirement, should the implementation plan for this be for 5 years like the other new raising the bar requirements? Further clarification is needed in R2.4.1 concerning load models that appropriately represent the dynamic behavior of loads. Is a NERC drafting team addressing these issues to determine an industry standard? If contingencies occur inside one utility that affect facilities in another utility, which utility is responsible for running these studies during the annual assessments? In R2.6.1, is there any limit to the time duration that a SPS and/or operating procedures can be used in the CAP? In Posting #2, undervoltage load shed, underfrequency load shed, and Special Protection Schemes were considered to be Non-Consequential Load Loss. In R2.6.1, installation or modification of Protection Systems or Special Protection Systems are now allowed as part of the Corrective Action Plan. Should undervoltage and underfrequency load shed also be allowed in the Corrective Action Plan? In R2.9, does the requirement require the maximum non-consequential load that can occur for contingencies in Table 1 or does it require just the maximum that a utility will allow on its system? Suggest clarifying permissible or perhaps using similar language as found in R2.8. Please explain the reason why Requirement R2.9 is needed in the Assessment. Reporting the largest Non-Consequential Load Loss doe not impact reliability. In R2.1, change the reference to requirement R2.6 (at the end of the last line) to R2.5. With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would

Organization	Question 2 Comment
	cause needless work to be performed on those plants or areas of the system where no changes are occurring. Recommend add the following to the end of R2.5.1: unless justification can be provided to demonstrate that the results of an older study are still valid. In Requirement R2.6.2, what constitutes a "project initiation date," and how will it be used? Please clarify. Please explain the reason why Requirement R2.8 is needed in the Assessment. Reporting the largest Consequential Load Loss does not impact reliability. R2.1 What's the value in being able to use qualified past studies if you have to use annual current studies Strike the words supplemented with and insert the word or R2.3 Insert the phrase one year of after the word addressing. In the subrequirements of 2.1.3 and 2.4.3, the use of the word timing is unclear. Consider using in service date or schedule for. In R2.6, does the Corrective Action Plan need to show all possible alternatives to fix a problem that has been identified - or does only one solution need to be shown for a problem?

Response: As written, Requirement R2 and Part 2.1.1 provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year Planning Assessment, and to assess other years in addition to those identified in Part 2.1.1. So the suggestion is already allowed as written. No change made.

The SDT does not feel that Part 2.3 raises the bar as entities should have been performing these studies all along. No change made.

Part 2.4.1 requires only that the Load model appropriately represent the dynamic behavior of Loads. It is up to the Planning Coordinator and Transmission Planner, who are closer to the issues in the planning area to determine the application of the Load models. No change made.

If Contingencies occur inside one utility that affect Facilities in another utility, the Planning Coordinator or Transmission Planner for the utility whose System is impacted would be responsible for performing the annual Assessment for those Contingencies known to cause the impact. A certain amount of coordination will need to occur between the utilities. The parties can then mutually agree upon a Corrective Action Plan.

Part 2.6 has been revised and included as Part 2.7 in the new version. In the fifth bullet in Part 2.6.1, the duration for use of an operating procedure is at the discretion of the Planning Coordinator or Transmission Planner because it may not be feasible to implement Transmission reinforcements in some locations.

> **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

UVLS and UFLS are not precluded in the Corrective Action Plan for those events where controlled Load shedding is allowed. The Standard does not address the acceptability of the tools to be used for any Corrective Action Plan. Part.2.6 does not specify how the Corrective Action Plan is written, it only requires that there is a plan to correct the potential problem identified in the Assessment. Therefore, it can be a number of alternatives or a single definitive alternative as long as the potential problem is addressed.

Organization	Question 2 Comment

Part 2.9 has been deleted.

In the new version, Part.2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

Part 2.5.1 has been revised and included as Part 2.6.1 to address your concerns.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

The SDT believes that Requirement R2, part 2.8 (now part 2.9) supports the objective of ensuring BES reliability by ensuring that the largest expected amount of Consequential Load Loss is reported in an open, transparent process. Part 2.9 has been clarified.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

In Part 2.1 it is envisioned that not all parts of the studies on which the Assessment is to be based can rely on past studies. For example, a study on year five performed during the past year may not be representative of year five in the current year. A past study can still be used if it can be demonstrated that the requirements for use of past studies are met.

Parts 2.1.3 (now Part 2.1.4) and 2.4.3 have been revised to reflect your suggestion.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

Organization	Question 2 Comment
	• Load level, Load forecast, or dynamic model assumptions. • Expected transfers. • Expected in service dates of new or modified Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. Part.2.6 does not specify how the Corrective Action Plan is written, it only requires that there is a plan to correct the potential problem identified in the Assessment. Therefore, it can be a number of alternatives or a single definitive alternative as long as the potential problem is addressed.
Exelon Transmission Planning	There are large amounts of resources required to perform the volume of studies required, including the dynamic and steady state sensitivities, extreme studies, and one-year lead time equipment spares. Many of these studies ultimately do not require additional consideration or reinforcement and have low threshold triggers, such as a 20 MW generation change. Performing these studies will be very burdensome to many TPs and result in few, if any, reliability benefits. We believe that the TP should be given more flexibility to allocate planning resources to areas of maximum benefit. The Spare Strategy in R2.1.4 is still not well defined. What types of equipment are included? How would a one-year lead time element be determined for consideration in this requirement? In R2.4.1, we recommend changing appropriately represents to a dynamic model appropriate for the type of stability study being performed? The TP should be allowed to perform only those specific stability studies needed and pertinent to its system. The same can be said about the dynamic load model. Differing interpretations are possible. We suggest changing the last sentence in R2.4.1 to .., a Load model shall be used which appropriately represents..An aggregate System Dynamic Load model which represents the overall dynamic behavior of the Load is acceptable. In 2.1.3 and 2.4.3 strike Expected from the phrase Expected transfers. Expected transfers should already be in the base case. In R2.5.2, the determination of a Material change is an engineering judgment issue and it should not be categorically defined here. There may be more significant material changes than a 20 MW increase in generation that would be better to study. In the phrase, For steady statesuch as generation or transmission additions/removals, or topology changes and would impact the study area, it is suggested to change would to could and impact the study area to significantly change the previous study results. The term should not be Corrective Action Plan, which implies a violation of a requirement. Suggest changing this term to Future Reliability Plan. What is the intended use for reporting the largest consequential and maximum non-consequential load loss amount and event? This would be a potential security concern if made public. There is a similar concern with the extreme event analysis. In 2.6.2 please define Initiation Date. While we appreciate your previous consideration of this comment, it is still not clear what this means. Is this the date of mitigation identification, regulatory approval date, construction start date, equipment procurement date, etc? If this is a commonly understood term not requiring a formal definition, could you then please

Organization	Question 2 Comment
	provide that definition in your response? If there is going to be a requirement to report on each contingency that results in non-consequential load loss it should be specified.

Response: If there are specific requirements in the standard that you feel would require the Transmission Planner to allocate their resources a certain way then you need to supply those specifics. As it stands, the SDT feels that the Transmission Planner can allocate resources any way they want. The standard does not dictate how they should meet requirements. No change made.

Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its system, or have an agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.4.1 has been revised to address your concerns.

2.4.1 System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

The SDT declines to strike "Expected Transfers" from Parts 2.1.3 (now Part 2.1.4) and 2.4.3. Parts 2.1.4 and 2.4.3 are sensitivity cases to be examined, which should cover conditions different from the base case. In any case, the Planning Coordinator or Transmission Planner are only required to examine one of the items from the list, and has the flexibility to choose other sensitivity cases if changes in expected transfer is not applicable.

Part 2.5.2 has been modified and included as Part 2.6.2. The SDT declines to change the term "Corrective Action Plan" to "Future Reliability Plan" because the Standard only requires the System performance to meet requirements. If a System meets requirements, then a Corrective Action Plan would not be necessary. An entity can still choose to install Transmission reinforcements for other reasons, but they would not be required by this Standard.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. The SDT does not believe that this requirement represents a security concern as rewritten.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2

Organization	Question 2 Comment
events in Table 1. In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: The comment – "If there is going to be a requirement to report on each contingency that results in non-consequential load loss it should be specified" does not reference any specific Requirement and therefore, the SDT can't respond. No change made.	
Southern Company	The Lower VSL describes a scenario where the TP or PC fails one or both of two particular sub-requirements. This language does not reconcile how failure of two sub-requirements is consistent with failure of only one of the same requirements. The recommendation is to restructure the VSL such that it is invoked when either sub-requirement is violated (not when both are violated). Generating unit stability has now been combined with system stability to be just one category - Stability. Previously, the shelf life of generating unit stability studies was indefinite -only needed to be restudied when system changes required it. Now the maximum shelf life of Stability studies is five years. Does this mean that generating unit stability studies must be repeated every five years whether system changes make it necessary or not? Requirement 2.3 stating that the short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon. It is not clear if the intent of the requirement is to study every year within Year One and year five. A statement similar to R2.1.1 Year One or two and year five for steady state analysis would be helpful. Some clarification is needed for R2.3 on the term Near-Term. Requirement 2.3 stating that "the analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area. What interrupting devices are included? Would the circuit breakers be enough? Moreover, the term System short circuit model is used for the first time (and the only time) here for the entire document. It is very common to use a different short circuit model for short circuit analysis while the steady state and stability analysis use different System models (power flow models). Some clarification is needed. R2.8 and R2.9 use the term megawatt "Demand". This is redundant. We suggest striking the word demand.
Response: The Lower VSL for Requirement R2 has been revised.	

R2 VSL	The responsible entity failed to comply with Requirement R2, part 2.9	The responsible entity failed to comply withRequirement R2, part 2.3 or part 2.8.	The responsible entity failed to comply with one of the following parts of Requirement R2: part 2.1,	The responsible entity failed to comply with two or more of thefollowing parts of Requirement R2: part 2.1,

Organization	Question 2 Comment			
			part 2.2, part 2.4, part 2.5, or part 2.7	part 2.2, part 2.4, or part 2.7.

Part 2.5.1 has been revised and included as Part 2.6.1 to address your concerns.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

The SDT declines to revise Part 2.3 to include short circuit analysis for one of the years in the Near-Term Transmission Planning Horizon because Part 2.3 only requires that a Planning Assessment be performed. Past studies can be used to support the Planning Assessment.

Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. Part 2.3 has been revised to provide greater clarity.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

The "megawatt" Is the qualifier for "Demand". The SDT believe it is clear as written. No change made.

Organization	Question 2 Comment
United Illuminating	R2 Comment We recommend replacing the phrase "prepare" with "conduct and document" in the first sentence. R2.1.1 Comment The requirement to evaluate year one or year two should be removed. This is not consistent with the time horizon identified in R2. R2.1.2 Comment The requirement should be removed. With no description of the system stresses and generator outages to be applied when assessing the off-peak load, it is difficult to imagine any issues which would arise which are not revealed in the peak load evaluation that could not be addressed through generation dispatch adjustments. R2.1.3 Comment - The emphasis on sensitivity testing in the existing section appears misdirected and should be focused on reasonable risk. The assessment should have to include a discussion of reasonable risk. The sensitivity list can be used to select sensitivities to assess risk. Having a requirement to perform one sensitivity just to meet the requirement of the standard does not add value to the assessment. R2.1.4 Priority Comment With respect to spare equipment strategy, this requirement imposes severe testing requirements upon the system. However, there is no discussion on the generation dispatch or system transfers that are to be used for this portion of the assessment. The expectations for changes in system stresses need to be clear as part of the standard. Additionally, this section does not contemplate changing the acceptability of load loss. After experiencing a major contingency such as this, some change in the acceptability of load loss should be expected. The standard should consider allowing Non-Consequential load loss for P1 & P2 events. The standard needs to allow Non-Consequential load loss for P3 & P4 events. Why doesn't the standard state (such as a transformer, generator or power electronic device) and not just

Organization	Question 2 Comment
	(such as a transformer). R2.2 Comment We suggest replacing the phrase “a current System peak Load study” with a valid System peak Load study in the first sentence. The word current is confusing as some read the word current to mean today’s rather than valid. R2.3 Comment Please provide guidance as to what year should be represented when performing short circuit studies. R2.4.1 Comment Change to read: “For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.5.1 Comment? We suggest deleting this requirement, and incorporating it into R2.5.2. R2.5.2 Comment To incorporate R.2.5.1 into R2.5.2; please modify the section as follows: For steady state, short circuit, or Stability analysis the study shall be less than five calendar years old or less: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. [A 20 MVA generator is fairly small in a 30,000 MW system and system concerns would already be addressed though the System Impact Study]? An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES determined to be material by the Planning Coordinator or Transmission Planner. R2.6 Priority Comment As written, this section undermines the value of the sensitivity testing. This section should require a corrective action plan to fix problems determined in sensitivity analysis if there is a reasonable risk of occurrence. We suggest making the standard read Provide documentation that explains the reasoning for the sensitivities considered and selected. R2.6 Comment At the end of the second sentence, the phrase “in the tables” is used. We suggest using more definitive language such as in Table 1. R2.6.2 Comment The phrase Project Initiation Date needs to be defined. It is unclear if this is this the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase “as well as an in-service date” should be modified to read “as well as a target in-service date”. R2.6.3 Comment Plans can provide a target in-service year but not an actual in-service year. R2.6.4 Priority Comment There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year’s assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient time to incorporate this into that year’s assessment and develop corrective actions. R2.8 Comment Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. R2.9 Comment This requirement is unclear. Is this requirement asking for each transmission planner to list their criteria for

Organization	Question 2 Comment
	non-consequential load loss, or is it asking how much non-consequential load loss was being relied upon in the assessment? We recommend that the requirement be modified to require documentation of the maximum amount of non-consequential load loss that was relied upon during the assessment.

Response: The SDT does not think that replacing "prepare" with "conduct and document" would add clarity, since Requirement R2 includes a requirement to document assumptions and results. No change made.

The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. No change made. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Part 2.1.2 requires that the Planning Coordinator and/or Transmission Planner also consider off-peak conditions because the System must be able to meet performance requirements over all demand levels. System peak condition may not represent all stressed conditions. For example, during off-peak, the Load is low, and the generation would have to be turned off to achieve Load-resource balance. Turning down resources within a Load area could result in reliability problems. Lowering the Load in areas with many non-dispatchable resources could also pose potential problems. As the System incorporates more and more renewable resources, some of them are non-dispatchable; a standard must be forward looking so the Planning Coordinator and Transmission Planner can identify potential problems as part of the Assessment. No change made.

Part 2.1.3 (now Part 2.1.4) has been rewritten to clarify the intent of the requirement. The requirement does not preclude a discussion of risk.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.

Organization	Question 2 Comment
	• Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of planned Transmission outages. In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Actions such as out of merit dispatch, operational restrictions, System reconfiguration can be part of a Corrective Action Plan if the System cannot meet performance requirements without the Facility in service. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.2 is intended to require a study performed in the current year, as opposed to studied performed in the past years. Part 2.2 has been revised to provide greater clarity. **2.2** The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6: For Part 2.3 the decision on the year to be represented in the study is left to the discretion of the Planning Coordinator or Transmission Planner. Part 2.3 only requires it to be either a study that was performed during the current year or in the past. For example, this year is 2009 and a study performed in 2009 is a current study, the study can investigate the System in a future year, which is at the discretion of the Planning Coordinator or Transmission Planner performing the study. Requirement R2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. Part 2.4.1 was revised but not changed as proposed because the intent of the last sentence is to allow the use of an aggregated System Load model as an appropriate Load representation. The suggested change could be read to mean that an aggregated System Load model would not appropriately represent the dynamic behavior of Loads. Parts 2.5 .1 and 2.5.2 (new Parts 2.6.1 and 2.6.2) were not combined. While the SDT appreciates the concern that a 20 MW generation addition can be small compared to a large System, a NERC standard needs to be clear as to the applicability. A requirement which contains "determined to be material by the Planning Coordinator or Transmission Planner" is not clear. Therefore, changing from 20 MW to "material" will also have to require justification from the Planning

Organization	Question 2 Comment
Coordinator or Transmission Planner on what is “material”. Material has been deleted. Part 2.6 has been modified and included as new Part 2.7. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur is more than one sensitivity). Although not required, the standard does not preclude the Planning Coordinator or Transmission Planner to develop Corrective Action Plans for high risk scenarios. However, if the scenario is high risk, then it should have been included in the base assumptions in the assessment and the Corrective Action Plan would have been required. The end of the second sentence has been changed to refer to Table 1 as suggested. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required. Part 2.6.4 allows the Planning Coordinator or Transmission Planner to address situations that are beyond its control by utilizing Non-Consequential Load Loss and/or curtailment of Firm Transmission Service, which are normally not permitted. Depending on the urgency of the need, the Corrective Action Plan may be developed outside the normal Assessment cycle at the discretion of the Planning Coordinator or Transmission Planner involved. Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Louisiana Energy and Power Authority	R2.5. This basic requirement intends, as we understand it, to require that earlier studies not be used for a current assessment if they are no longer accurate. But the phrasing is potentially confusing, and would be clearer if revised. Since the requirement deals with the use of past studies, we suggest that R2.5.2 be revised to state that the study may be used only if there have been no material changes, so that R2.5 reads in full:R2.5. Past studies may be used to support the Planning Assessment if they meet the following requirements: R2.5.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less. R2.5.2. For steady state, short circuit, or Stability analysis: the study may be used only if there have been no material changes, such as generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability of 20 MW or greater. An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES which total 20 MW or greater. With respect to footnote 10 to Table 1, we fear that the flexibility suggested by those provisions may be excessive for a planning standard. The ambiguity occasioned by stating emergency actions that can properly be taken in a planning standard can be utilized by those who plan the system in a manner which plans to drop non-consequential loads just as footnote b has been used in the past. If this is intended to raise the bar as stated these provisions do not belong in a

Organization	Question 2 Comment
	planning standard, at least as now stated. It may be appropriate to remove the reference to footnote 10, at least in the Initial System Condition entry in P3, where it suggests that it can be invoked after loss of a single generator, and we request the SDT to review that footnote to assure that it is appropriate in the other entries to which it is applied.

Response: Part 2.5 has been revised and included as Part 2.6 as shown.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Footnote 10 (now footnote 9) was added to address the disjoint between how some parties calculate ATC/AFC when assessing Long Term Firm Transmission Service and the currently proposed TPL-001-1 standard. TPL-001-1 requires Transmission Planners to plan their systems to meet multiple contingency events and some parties assess Long Term Firm Transmission Service on a first Contingency basis. Units obligated to re-dispatch, as contemplated in Footnote 9 are those units which are contractually bound to provide the service as well as those obligated to provide the service under Network Integrated Transmission Service, under FERC's pro forma OATT. Under the pro forma OATT, units designated as network resources receiving NITS are obligated to re-dispatch as requested by the Transmission Provider pursuant to Section 33.2 to maintain reliability. The footnote is worded such that curtailment/re-dispatch cannot result in the loss of firm Load preserves the guidance given by FERC in Order 693 that no single Contingency result in the loss of firm Load. No change made.

The SDT has reviewed the application of footnote 10 (now footnote 9) and believes that it is correct. No change made.

Organization	Question 2 Comment
System Protection and Transmission Planning Department	R2 - The term "Stability Analysis" is used frequently in the standard, but is not clearly defined. Based on an IEEE paper ("Definition and Classification of Power System Stability," Kundar, et al) there are 5 different categories of stability analysis: 1)small signal angle stability; 2) transient angle stability; 3) frequency stability; 4) large disturbance voltage stability; and 5) small disturbance voltage stability. Does the writing committee intend to make the analysis of all these types of stability issues mandatory? I recommend inserting a new definition into the standard for stability as follows: "Stability Analysis - The study of the bulk electric power system's ability, for a given initial operating condition, to regain a state of operating equilibrium after being subjected to a physical disturbance. There are 5 accepted categories of power system stability: 1) small signal angle stability; 2) transient angle stability; 3) frequency stability; 4) large disturbance voltage stability; and 5) small disturbance voltage stability. While there are situations that exist that require small signal angle and voltage stability analysis, only transient angle stability, frequency stability, and large disturbance voltage stability analysis are generally relevant to system planning performance assessments. R2.1.4 is a new requirement directing studies to consider impacts of spare equipment strategy. Does this require the TP to run scenario analysis without certain transformers? It is not clear what is required. How many spare transformers are required? What reliability level is acceptable? R2.1.4 The one year cut-off seems arbitrary. One MONTH may be unacceptably long in some cases. Instead of one year or more, we suggest the requirement state an extended time period.

Organization	Question 2 Comment
	R2.2. The wording on this requirement is not clear. Is it trying to say that a long-term (5-10 year) peak loading study is required to be performed annually R2.2: What is meant by the term current System peak Load study A powerflow study performed under expected peak-load conditions? Or a forecast of peak loads? R2.3 A short circuit analysis requirement is now added to Planning Assessment requirements. Short circuit analysis appears to be in the standard to document adequate ratings for interrupting equipment. That would be the purpose of short circuit studies we perform. If there are other intended meanings, then additional detail is needed. R2.3 We do not agree that a short circuit analysis needs to be conducted annually. The requirement for a new short circuit duty study should be driven by changes in the system, as is done for powerflow study work. In short, until system changes are made, we would not anticipate higher fault duties, and there would be no reason to rerun studies. R2.4.1 requires dynamic load models. Development of dynamic load models is ongoing, and therefore will need a much longer implementation period than the steady state portions of the standard. We are not sure two years will be enough. It depends partly on pending work that is not under our control.R1.1.2, R2.1.4, R2.5.2, R3.3.4, R4.3.3, R5 When text of a Standard Requirement includes the phrase such as or could include, then gives a list of possible choices, we take it to mean “just one of these items, or none of these, or something not listed here”. In other words, such as lists are really non-required, non-interpretable, non-measurable options. They should not be included in requirements. Lists such as these belong in transmittal notes and associated SDT commentary, not in Compliance Standard Requirements. R2.5.2 Limits such as “addition/deletion/change to a group of generating units . . . which total 20 MW or greater. are not always appropriate. Appropriateness of Generation netting with load should depend on system size and engineering judgment, not artificial limits. The suggestion list following generation changes could include: should be eliminated. R2.6.2. For the Near-Term Transmission Planning Horizon, include both a project initiation date as well as an in-service date? The assessment report should not require a full project development just a description of what is required to provide adequate service within specified operating criteria. The term project initiation is not clear. Requirement R2.6.2 should be eliminated. R2.8. The Planning Assessment shall provide the largest Consequential Load Loss (megawatt Demand) and the associated event caused by any P1 event and any P2 event in Table 1. is complicated, and may require new modeling software capability to comply. Software vendors would develop this capability. Why is this required? What is the expected benefit to system reliability?

Response: The SDT disagrees that the Standard should include a definition of Stability analysis because it is covered in Requirement R2. “Stability analysis” is not a defined NERC term and is not intended to be defined as in IEEE; however, it does not conflict with the IEEE definition. No change made.

Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won’t last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, and may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its system, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than

Organization	Question 2 Comment

one year. The Planning Coordinator and/or Transmission Planner will need to decide which pieces of major Equipment in their respective Systems would be more vulnerable to long term outage. In Part 2.1.5 when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2 has been revised to provide greater clarity. The standard will require that a study for one year within the Long-Term Transmission Planning Horizon be conducted. The Planning Assessment can be supplemented by past studies.

2.2 The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6:

Part 2.3 has been revised to provide greater clarity. In addition, Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. The Assessment is to be supported by a current or past study. Therefore, annual short circuit study is not required if no material change has occurred.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.4.1 allows the use of an aggregate System Load model which represents the overall dynamic behavior of the Load that could impact the study area. Part 2.4.1 has been revised to provide greater clarity. In addition, the SDT was not able to locate the phrase "such as" in Requirement R2.4.1. There were two places in Requirement R2 that this phrase appears (Parts 2.1.4 and 2.5.2). In both instances, what follows were examples and not requirements.

2.4.1 System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Part 2.5.2 has been revised and included as Part 2.6.2 to address your concerns.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with

Organization	Question 2 Comment
Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Part 2.8 is intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed the requirement and agrees that as written it was unclear. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
PPL Energy Plus	The standard appropriately recognizes that the planning horizon must be as long as the longest lead-time system upgrade, typically 8+ years for a new line. However, while Requirement 2.2.1 states this, it could be more clearly stated. Requirement R2.5.2 should be clarified to point out if the TP has discretion or if the 20 MW is binding. Requirement R2.6.4 should require TP's and PC's to post on an OASIS to assure easy access by affected parties to information on what is "beyond the control of these organizations. Please retain Requirements 2.8 and 2.9 as these are good measures of the quality of the plan produced by the planners.
Response: Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead time longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected. Part 2.5.2 (now Part 2.6.2) has been revised to address your suggestion. Both bullets included references to 20 MW have been deleted from the revised standard. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. The SDT declines to require a specific venue for the Planning Coordinator and/or Transmission Planner to post the information regarding Part 2.6.4. The way information is shared should be left to the individual entities involved in accordance with Requirement R7, included in the new version as Requirement R8. Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and finds that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
PacifiCorp SRP Arizona Public Service Co	Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault). Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this

Organization	Question 2 Comment
Southern California Edison Company Pacific Gas and Electric Co, California ISO Idaho Power San Diego Gas and Electric Co	could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer. This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. We also recommend changing this from a separate sub-Requirement to one of the sensitivities to be considered under 2.1.3. We also believe that the statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement. The 20 MW threshold identified as material change for generation in R2.5 is too small. The limit should be raised or based on a percentage of the study area's installed generating capacity. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event if it is documented? R2.9 should be deleted. It is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent, among other things, on the types of load being served. It very well may be a case by case situation.
NV Energy	Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault).R2.1.3 should be modified to remove the last bullet point. Transmission outages should be a part of operational study work not planning study work. Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer. This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. We also recommend changing this from a separate sub-Requirement to one of the sensitivities to be considered under 2.1.3. We also believe that the statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement. The 20 MW threshold identified as material change for generation in R2.5 is too small. The limit should be based on a percentage of the study area'sinstalled generating capacity. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event if it is documented R2.9 should be deleted. It is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent,

Organization	Question 2 Comment
	among other things, on the types of load being served. It very well may be a case by case situation.
Western Area Power Administration	Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault).The last bullet under R2.1.3 - "Planned duration or timing of Transmission Outages." does not belong in a long-term planning standard. These-type of seasonal outages are studied and implemetation plans are derived as part of the TOP Standard requirements. In the WECC - this is also covered by the seasonal studies carried out by the Operating Transfer Capability Policy Committee (OTCPC) study groups. Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer. This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. We also recommend changing this from a separate sub-Requirement to one of the sensitivities to be considered under 2.1.3. We also believe that the statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement - OR simply delete this spare equipment requirement. The 20 MW threshold identified as material change for generation in R2.5 is too small. The limit should be raised or based on a percentage of the study area’s installed generating capacity. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event if it is documented? R2.9 should be deleted. This requirement is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent, among other things, on the types of load being served. It very well may be a case by case situation.

Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt. Even though the effects of short circuit capability are localized and may be related to new planned Facilities, it is important to BES reliability. Part 2.3 has been revised to provide greater clarity.

> **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Organization	Question 2 Comment
2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.5 has been revised and included as Part 2.6 as shown. The references to a 20 MW threshold have been deleted from the revised standard. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Western Area Power Administration	Short-circuit studies as related to maintaining adequate protection devices and systems are normally performed either by a specific System Protection Group/Department or System Maintenance Department and should not be in this requirement, but Post-Transient Analysis to mitigate voltage collapse scenarios should be included (includes R2.5.1 & R2.5.2). Also, System Protection including mitigation of short-circuit duty above installed facilities capabilities or for new planned facilities are already covered by the PRC Standards and need not be included and duplicated in the TPL Planning Standard such as in R2.3 & R2.7.
Response: Parts 2.3 and 2.7 are intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt, and develop Corrective Action Plan is needed. As such, they are not specifically related to new planned Facilities. Requirement for Post-transient voltage collapse is included in Table 1, Header note (a), which states "Voltage instability, cascading outages, and uncontrolled islanding shall not occur." No change made.	
Tampa Electric	R2.1 should state R2.5 at the end of requirement instead of R2.6 R2.1.4 Consider revising to only include P0-P2 contingencies. R2.5.1 please clarify whether the 5 years is from the beginning of the assessment or end of the assessment. R2.6 Consider changing the terminology for "Corrective Action Plan" to "Transmission Plan" R2.8 Please clarify the reason for this requirement. This is not necessary for reliability and the effort to collect this information is substantial and does not benefit the BES. R2.9 Please clarify the reason for this requirement. This is not necessary for reliability and the effort to collect this

Organization	Question 2 Comment
	information is substantial.
Response: In the new version, Part.2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. For Part 2.5.1 the 5 years should be measured from the completion of the past study to be used to support the current Planning Assessment. However, Part 2.5.1 has been revised and included as Part 2.6.1, which will allow the use of studies older than 5 years if a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. In Part 2.6, the SDT declines to change the term "Corrective Action Plan" to "Transmission Plan" because the Standard only requires the System performance to meet requirements. If a System meets requirements, then a Corrective Action Plan would not be necessary. An entity can still choose to install Transmission reinforcements for other reasons, but they would not be required by this Standard. Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Requirement R2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Florida Reliability Coordinating Council, Inc - Transmission Working Group	Incorrect reference shown at the end of R2.1. The appropriate reference should be R2.5. The end of the first sentence of R2.3 should have a reference to R2.5. The end of the first sentence of R2.4 should have a reference to R2.5. R2.1.4 - Please consider revising this for the analysis to include only Contingencies P0-P2 in Table 1. Alternatively we suggest moving this requirement to be under sections 2.1.3 and 2.4.3 and treated as a sensitivity. R2.5 ? This requirement is very valuable in clarifying that past studies can be used and what criteria needs to be met for them to be used. However it is not clear if all new studies could be met using past studies (e.g. a small system with very few changes year to year) of if some sub-requirements require a new study every year, with past studies only used as supporting information. If the intent is that some sub-requirements can not be met with past studies, then consider making that clear through a foot note or a list under Section 2.5 listing which study requirements may depend only past studies that are still current.

Organization	Question 2 Comment
	R2.5.1 Please clarify if the 5 calendar years is from the date the assessment is “finished” or the date the study process for the assessment begins. R2.5.2 the identified 20 MW threshold is extremely small and would be doubtful to change the response of the BES. This requirement could also be interpreted that a previous study where the base case is not identical to the current planning case could be used. Please consider the following proposed language: For steady state, short circuit, or Stability analysis: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period that would impact the study area. (not show the list) R2.6 - Requiring sensitivities but not requiring that they meet specific performance requirements is a sound approach.R2.6 requires a corrective action plan when performance will not be met in the simulations. However, if an entity has already planned a needed facility and/or operation steps for a given conditions, the simulations will not show any deficiencies and therefore no corrective action plan is required. The term Corrective Action Plan implies that the situation is wrong or incorrect, consider changing the approach to be to require an entity to have a planning and Operations plan, Improvement Action Plan?, or simply a Transmission Plan that includes all facilities planned for the BES and descriptions of conditions where an operational process is being used. R2.6.1 (Bullet 2) This requirement should also account for the removal of a Special Protection Systems: Installation, modification or removal of Protection Systems or Special Protection Systems?. R2.6.4 This is an excellent addition R2.8 Please explain the reason for this requirement. The effort required to collect this data is substantial and does not have any benefit to the BES. R2.9 Please explain the reason for this requirement. It seems to cause Entities to develop performance criteria for themselves for Multiple and Extreme Contingencies that are not in Table 1. The effort required to collect this data to compare against any self-imposed criteria is substantial and does not have any benefit to the BES. The requirement will result in inconsistency across North America. There is also no discussion of what happens if a Multiple or Extreme contingency is shown to exceed the Entity’s self-imposed criteria, is the Entity then non-compliant? If so, what if the Entity simply changes the self-imposed criteria? We suggest eliminating this requirement.

Response: In the new version, Part.2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference.

Parts 2.3 & 2.4 have been revised to reflect your suggestion.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4 The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part2.6. The following studies are required.

Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the

Organization	Question 2 Comment
System is expected to experience due to the possible unavailability of the long lead time equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. For Part 2.5.1 the 5 years should be measured from the completion of the past study to be used to support the current Planning Assessment. However, Part 2.5.1 has been revised and included as Part 2.6.1, which will allow the use of studies older than 5 years if a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. Part 2.5.2 has been revised and included as Part 2.6.2 to provide greater clarity. The references to a 20 MW threshold have been deleted from the revised standard. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. In Part 2.6 (now Part 2.7), the SDT declines to change the term "Corrective Action Plan" to "Transmission Plan" because the Standard only requires the System performance to meet requirements. If a System meets requirements, then a Corrective Action Plan would not be necessary. An entity can still choose to install Transmission reinforcements for other reasons, but they would not be required by this Standard. Although additions of Protection Systems and Special Projection Systems are usually associated with projects to enable the System to meet performance requirements, the second bullet in Part 2.7 has been modified to include removal of Protection Systems or Special Protection Systems to provide greater clarity. **2.7 bullet 2:** Installation, modification, or removal of Protection Systems or Special Protection Systems Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
FMPA	Incorrect reference shown at the end of R2.1. The appropriate reference should be R2.5. The end of the first sentence of R2.3 should have a reference to R2.5. The end of the first sentence of R2.4 should have a reference to R2.5. R2.1.4, what does (t)he analysis shall reflect the Contingencies identified in Table 1 mean? Is the intention similar to sensitivities, where there is no direct requirement to meet the performance standards of Table 1? If so, why not include loss of a long lead time Facility followed by other contingencies one of the Sensitivities and not have a separate sub-requirement for it? Or, is the intention that the TP and PC must meet the performance requirements of Table 1 considering the outage of a long lead time Facility? We hope that the intent is not to require Entities to be able to meet the performance requirements

Organization	Question 2 Comment
	of Table 1 assuming a long lead time Facility out of service. If that is the intent, then we believe that only Contingencies P0-P2 in Table 1 ought to apply to Requirement R2.1.4. Otherwise, Requirement R2.1.4 would require building transmission to triple contingency (N-3) criteria. Contingency P3 requires building transmission to a single contingency plus a generator outage (a double contingency that has the same performance criteria requirements as single contingencies). Since generators are long term lead Facilities that no one that we know of carries spares for, R2.1.4 as written would mean that Contingency P3 becomes two generators out of service with system adjustments followed by another contingency (N-3). This would have the (possibly unintended) consequences of significantly reducing long-term firm ATC since utilities will likely use TRM to account for the potential for long-term outages. If meeting the criteria of Table 1 is the intent of the SDT, then a potential way to address this is to restate R2.1.4 to state that only P0 through P2 (zero and single contingency) apply to R2.1.4.If meeting the performance criteria of Table 1 is the intent of the SDT for R2.1.4, then we also believe that R2.1.4 should also only apply to the EHV and not the HV system. Yes, when a major piece of equipment such as a transformer fails, it could be out for a long period of time; however, a transformer failure is far less probable than an over-head transmission line failure (e.g., a transformer failure is in the range of a once in 50 year event, whereas a transmission line fails probably once a year or once every other year, almost two orders of magnitude difference). A major 500 kV/230 kV autotransformer failure will have a far larger radius of impact than a 230 kV/138 kV autotransformer meant to serve the local area, giving additional support to purchasing a spare transformer for the 500/230 kV auto (EHV system). A small utility with only one or two 230 / 138 kV autos does not have sufficient justification to purchase a spare autotransformer due to the very low failure rate and the much more localized purpose of the transformer. If the intent of the SDT is to meet the performance requirements of Table 1 for R2.1.4, then the standard would essentially cause many small utilities who cannot justify spare autos to plan to serve only load and significantly reduce ATC in the planning horizon. Based on the lesser impact of HV connected autos as compared to EHV connected autos, and if the intent of the SDT is to meet the performance requirements of Table 1 for R2.1.4, then we would recommend that, for auto-transformers, R2.1.4 should only be applicable to EHV connected auto-transformers. R2.8 Please explain the reason for this requirement. The effort required to collect this data is substantial and does not have any benefit to the BES. R2.9 Please explain the reason for this requirement. It seems to cause Entities to develop performance criteria for themselves for Multiple and Extreme Contingencies that are not in Table 1. The effort required to collect this data to compare against any self-imposed criteria is substantial and does not have any benefit to the BES. The requirement will result in inconsistency across North America. There is also no discussion of what happens if a Multiple or Extreme contingency is shown to exceed the Entity's self-imposed criteria, is the Entity then non-compliant? If so, what if the Entity simply changes the self-imposed criteria?

Response: In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference.

Parts 2.3 and 2.4 have been revised to reflect your suggestion.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned

Organization	Question 2 Comment
	generation and Transmission Facilities in service which could impact the study area. **2.4** The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part 2.6. The following studies are required. Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Transmission Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. The Planning Coordinator and/or Transmission Planner will need to decide which pieces of major Equipment in their respective systems would be more vulnerable to long term outage. In Part 2.1.5 when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.
Progress Energy Carolina (PEC)	PEC believes that "R2.1.1. System peak Load for either Year One or year two, and for year five" is unneccesarily prescriptive. PEC recommends eliminating the Year One or year two addition. PEC believes that R2.1.4. concerning an entity's spare equipment strategy is overly conservative. The standard should only require N-2 deep planning and not N-3. PEC believes that for R2.4.1 "a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads" should be clarified to include "as appropriate" clause. Induction motor load modeling should not be required for all dynamic studies. PEC believes that for R2.5.2. The language "For steady state, short circuit, or Stability analysis: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area" needs to be made more clear. The important point is that material changes must be modeled if they have occurred. Also the 20MW threshold is far too small to be material. PEC believes that R2.8. and P2.9 are unnecessary and should be removed.

Organization	Question 2 Comment
Response: Requirement R2, part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the Near-Term Transmission Planning Horizon: (1) A year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled; (2) A Year One or year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. The standard provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment, and to assess other years in addition to those identified in Requirement R2, part 2.1.1. No change made. Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. In Part 2.1.5 when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.4.1 allows the use of an aggregate System Load model which represents the overall dynamic behavior of the Load that could impact the study area. Part 2.4.1 has been revised to provide greater clarity. **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable. Part 2.5.2 has been revised and included as Part 2.6.2 to address your concerns. The references to a 20 MW threshold have been deleted from the revised standard. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
CPS Energy	As written, is it the intent of Requirement R2.1.4. to escalate the contingencies in Table 1 from "N-1" to "N-2" and "N-2" to N-3" for long lead-time replacement equipment, such as autotransformers and GSUs? If so, we feel that this requirement is

Organization	Question 2 Comment
	overly burdensome that will result in unnecessary expense to the customers. In Requirement R2.4.1., what is the intent of the second sentence if an aggregate system load model is acceptable? We feel that the second sentence should be removed. In Requirement R2.6.2., we feel that statement of the project initiation date has no benefit and should be removed as a requirement. The required in-service date should be adequate. We do not believe that there is any benefit to reliability by documenting the Consequential and Non-Consequential Load Loss data required by Requirements R2.8. and R2.9.

Response: Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

In Part 2.4.1, the intent for the second sentence is that if more accurate Load Model is available it should be used. The standard should not inadvertently disallow improved Load modeling.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

Organization	Question 2 Comment
MidAmerican Energy Company	MidAmerican commends the SDT for all its hard work on this standard. MidAmerican offers the following comments on R2: MidAmerican believes that the second sentence of R2.3 as written will result in unnecessary modeling for the required short

Organization	Question 2 Comment
	circuit analysis. MidAmerican recommends that the sentence The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study area. MidAmerican recommends that R2.3 be changed by deleting the words any and could and replace with the words materially. In this way, the sentence would read, They analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with generation and Transmission Facilities in service which materially impact the study area. Requirement 2.5 is too confining and is complicated and unnecessary. MidAmerican asks that the requirement be deleted in its entirety. Alternatively, if the SDT does not agree with deleting all of R2.5, then MidAmerican asks that the SDT consider deleting the R2.5.1. MidAmerican believes R2.4 will ensure that analysis is fresh by requiring a certain number of studies be conducted for certain years in the planning horizon. Why add the requirement for no older than 5 calander years? With the R2.4 and the material requirements in R2.5.2 shouldn't that be more than enough to ensure that the analysis is fresh enough to support the assessment?? If R2.5.2 is not deleted, the words and interconnected to the Bulk Electric System should be added behind 20 MW or greater. Requirement 2.6.2 requires the project initiation date. MidAmerican recommends that the SDT delete the requirement to provide this date as an initiation date is not related to system reliability. If the SDT believes it is critical to get this date, then the SDT should define it. Does it mean when engineering starts, when it is decided to proceed, or something else? At a minimum, MidAmerican believes that the SDT should add the word expected behind largest to avoid unnecessary compliance issues for an unexpected event, and clarify that R2.8 and R2.9 are not required for sensitivity cases.

Response: Part 2.3 has been revised to provide greater clarity. However, the SDT declines to make the changes suggested because Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt, and develop a Corrective Action Plan as needed. As such, they are not specifically related to individual new planned Facilities.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Deleting Part 2.5 would leave no guidance on when past studies can be used to support current Assessment. This can increase work load. Part 2.5 has been revised and included as Part 2.6 as shown.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

In our last meeting the SDT agreed to revise Part 2.6 (and included it as Part 2.7) and project initiation date is no longer required.

Organization	Question 2 Comment
2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Deseret Generation & Transmission	R2.5.2 For Past studies to be used in the Planning Assessment, the suggestion that the addition of a 20 MW generator would disqualify those past studies is way too restrictive. It should be left up to the Transmission Planner to evaluate the applicabililty of past studies and the two sub bullets should be removed and replace with a general statement about past studies should adequately represent the present system to be used in the Planning Assessment. Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault). Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer. This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. We also recommend changing this from a separate sub-Requirement to one of the sensitivities to be considered under 2.1.3. We also believe that the statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the “largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event” if it is documented? R2.9 should be deleted. It is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent, among other things, on the types of load being served. It very well may be a case by case situation.
Response: Part 2.5.2 has been revised and included as Part 2.6.2 to address your concerns. The references to a 20 MW threshold have been deleted from the revised standard. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to	

Organization	Question 2 Comment
demonstrate that System changes do not impact the performance results in the study area. Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. Part 2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.6 has been modified and included as new Part 2.7. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur is more than one sensitivity). Part 2.7.2 has also been added to require that the Corrective Action Plan include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur is more than one sensitivity). **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: **2.7.2** Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary. Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in he new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Northeast Utilities	R2 Comment We recommend replacing the phrase prepare with conduct and document in the first sentence. R2.1.1 Comment The requirement to evaluate year one or year two should be removed. This is not consistent with the time horizon identified in R2. R2.1.2 Comment The requirement should be removed. With no description of the system stresses and generator outages to be applied when assessing the off-peak load, it is difficult to imagine any issues which would arise which are not revealed in the peak load evaluation that could not be addressed through generation dispatch adjustments.

Organization	Question 2 Comment
	R2.1.3 Comment - The emphasis on sensitivity testing in the existing section appears misdirected and should be focused on reasonable risk. The assessment should have to include a discussion of reasonable risk. The sensitivity list can be used to select sensitivities to assess risk. Having a requirement to perform one sensitivity study just to meet the requirement of the standard does not add value to the assessment. R2.1.3 Comment - What should be the time duration for the bullet that reads Planned duration or timing of Transmission outages R2.1.4 Priority Comment With respect to spare equipment strategy, this requirement imposes severe testing requirements upon the system. However, there is no discussion on the generation dispatch or system transfers that are to be used for this portion of the assessment. The expectations for changes in system stresses need to be clear as part of the standard. Additionally, this section does not contemplate changing the acceptability of load loss. After experiencing a major contingency such as this, some change in the acceptability of load loss should be expected. The standard needs to allow Non-Consequential load loss for P3 & P6 events when spare equipment strategy is incorporated in the testing. An example of such an event, that non-consequential load loss should be acceptable, would be a long-term outage of one transformer at a station which would be modeled in the base, followed by event P6 testing on initial system condition of a transformer out of service then followed by a 2nd transformer outage. This would be three transformers out at the same station and this could approach Extreme Events Contingency. R2.2 Comment We suggest replacing the phrase a current System peak Load study with a valid System peak Load study in the first sentence. The word current is confusing, as some read the word current to mean today's rather than valid. R2.3 Comment Please provide guidance as to what year should be represented when performing short circuit studies. R2.4.1 Comment ? Change to read: "For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.5.1 Comment" We suggest deleting this requirement, and incorporating it into R2.5.2. R2.5.2 Comment To incorporate R.2.5.1 into R2.5.2; please modify the section as follows: For steady state, short circuit, or Stability analysis the study shall be less than five calendar years old or less: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. [A 20 MW generator is fairly small in a 30,000 MW system and system concerns would already be addressed through the System Impact Study]?An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES determined to be material by the Planning Coordinator or Transmission Planner. R2.6 Priority Comment As written, this section undermines the value of the sensitivity testing. This section should require a corrective action plan to fix problems determined in sensitivity analysis if there is a reasonable risk of occurrence. We suggest making the standard read Provide documentation that explains the reasoning for the sensitivities considered and selected. R2.6 Comment At the end of the second sentence, the phrase in the tables is used. We suggest using more definitive language such as in Table 1.

Organization	Question 2 Comment
	R2.6.2 Comment The phrase Project Initiation Date needs to be defined. It is unclear if this is the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase as well as an in-service date should be modified to read as well as a target in-service date. R2.6.3 Comment Plans can provide a target in-service year but not an actual in-service year. R2.6.4 Priority Comment There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year's assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient time to incorporate this into that year's assessment and develop corrective actions. R2.8 Comment Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. R2.9 Priority Comment We highly recommend that the standard should not allow non-consequential load loss to resolve any violation arising from the planning events in Table 1. Therefore, this requirement should be deleted.
ISO New England, Inc.	R2 Comment We recommend replacing the phrase prepare with conduct and document in the first sentence. R2.1.1 Comment The requirement to evaluate year one or year two should be removed. This is not consistent with the time horizon identified in R2. R2.1.2 Comment The requirement should be removed. With no description of the system stresses and generator outages to be applied when assessing the off-peak load, it is difficult to imagine any issues which would arise which are not revealed in the peak load evaluation that could not be addressed through generation dispatch adjustments. R2.1.3 Comment - The emphasis on sensitivity testing in the existing section appears misdirected and should be focused on reasonable risk. The assessment should have to include a discussion of reasonable risk. The sensitivity list can be used to select sensitivities to assess risk. Having a requirement to perform one sensitivity just to meet the requirement of the standard does not add value to the assessment. R2.1.4 Priority Comment With respect to spare equipment strategy, this requirement imposes severe testing requirements upon the system. However, there is no discussion on the generation dispatch or system transfers that are to be used for this portion of the assessment. The expectations for changes in system stresses need to be clear as part of the standard. Additionally, this section does not contemplate changing the acceptability of load loss. After experiencing a major contingency such as this, some change in the acceptability of load loss should be expected. The standard should consider allowing Non-Consequential load loss for P1 & P2 events. The standard needs to allow Non-Consequential load loss for P3 & P4 events. Why doesn't the standard state (such as a transformer, generator or power electronic device) and not just (such as a transformer). R2.2 Comment We suggest replacing the phrase a current System peak Load study with a valid System peak Load study in the first sentence. The word current is confusing as some read the word current to mean today's rather than valid. R2.3 Comment Please provide guidance as to what year should be represented when performing short circuit studies. R2.4.1 Comment Change to read: For peak System Load levels, a Load model shall be used which appropriately

Organization	Question 2 Comment
	represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.5.1 Comment? We suggest deleting this requirement, and incorporating it into R2.5.2.R2.5.2 Comment To incorporate R.2.5.1 into R2.5.2; please modify the section as follows: For steady state, short circuit, or Stability analysis the study shall be less than five calendar years old or less: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. [A 20 MVA generator is fairly small in a 30,000 MW system and system concerns would already be addressed though the System Impact Study]? An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES determined to be material by the Planning Coordinator or Transmission Planner. R2.6 Priority Comment As written, this section undermines the value of the sensitivity testing. This section should require a corrective action plan to fix problems determined in sensitivity analysis if there is a reasonable risk of occurrence. We suggest making the standard read Provide documentation that explains the reasoning for the sensitivities considered and selected. R2.6 Comment At the end of the second sentence, the phrase in the tables is used. We suggest using more definitive language such as in Table 1. R2.6.2 Comment The phrase Project Initiation Date needs to be defined. It is unclear if this is this the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase as well as an in-service date should be modified to read as well as a target in-service date. R2.6.3 Comment Plans can provide a target in-service year but not an actual in-service year. R2.6.4 Priority Comment There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year's assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient time to incorporate this into that year's assessment and develop corrective actions. R2.8 Comment Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. R2.9 Comment This requirement is unclear. Is this requirement asking for each transmission planner to list their criteria for non-consequential load loss, or is it asking how much non-consequential load loss was being relied upon in the assessment? We recommend that the requirement be modified to require documentation of the maximum amount of non-consequential load loss that was relied upon during the assessment.
Central Maine Power Company	R2 Comment We recommend replacing the phrase prepare with conduct and document in the first sentence. R2.1.1 Comment The requirement to evaluate year one or year two should be removed. This is not consistent with the time horizon identified in R2.

Organization	Question 2 Comment
	R2.1.2 Comment The requirement should be removed. With no description of the system stresses and generator outages to be applied when assessing the off-peak load, it is difficult to imagine any issues which would arise which are not revealed in the peak load evaluation that could not be addressed through generation dispatch adjustments. R2.1.3 Comment - The emphasis on sensitivity testing in the existing section appears misdirected and should be focused on reasonable risk. The assessment should have to include a discussion of reasonable risk. The sensitivity list can be used to select sensitivities to assess risk. Having a requirement to perform one sensitivity just to meet the requirement of the standard does not add value to the assessment. R2.1.4 Priority Comment With respect to spare equipment strategy, this requirement imposes severe testing requirements upon the system. However, there is no discussion on the generation dispatch or system transfers that are to be used for this portion of the assessment. The expectations for changes in system stresses need to be clear as part of the standard. Additionally, this section does not contemplate changing the acceptability of load loss. After experiencing a major contingency such as this, some change in the acceptability of load loss should be expected. The standard should consider allowing Non-Consequential load loss for P1 & P2 events. The standard needs to allow Non-Consequential load loss for P3 & P4 events. Why doesn't the standard state "(such as a transformer, generator or power electronic device)" and not just "(such as a transformer)". What constitutes "spare equipment strategy" Would a strategy that involves out-of-merit dispatch or operational restrictions be considered a valid "spare equipment strategy". If a transformer is lost, could a reconfiguration of transmission constitute a valid "spare equipment strategy"? R2.2 Comment We suggest replacing the phrase a current System peak Load study with a valid System peak Load study in the first sentence. The word current is confusing as some read the word current to mean today's rather than valid. R2.3 Comment Please provide guidance as to what year should be represented when performing short circuit studies. R2.4.1 Comment Change to read: For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.5.1 Comment We suggest deleting this requirement, and incorporating it into R2.5.2. R2.5.2 Comment To incorporate R.2.5.1 into R2.5.2; please modify the section as follows:For steady state, short circuit, or Stability analysis the study shall be less than five calendar years old or less: the present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. [A 20 MVA generator is fairly small in a 30,000 MW system and system concerns would already be addressed though the System Impact Study]? An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES determined to be material by the Planning Coordinator or Transmission Planner. R2.6 Priority Comment As written, this section undermines the value of the sensitivity testing. This section should require a corrective action plan to fix problems determined in sensitivity analysis if there is a reasonable risk of occurrence. We suggest making the standard read Provide documentation that explains the reasoning for the sensitivities considered and

Organization	Question 2 Comment
	selected. R2.6 Comment At the end of the second sentence, the phrase in the tables is used. We suggest using more definitive language such as in Table 1?. R2.6.2 Comment The phrase Project Initiation Date needs to be defined. It is unclear if this is this the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase as well as an in-service date should be modified to read as well as a target in-service date?. R2.6.3 Comment Plans can provide a target in-service year but not an actual in-service year. R2.6.4 Priority Comment There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year's assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient time to incorporate this into that year's assessment and develop corrective actions. R2.8 Comment Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. R2.9 Comment This requirement is unclear. Is this requirement asking for each transmission planner to list their criteria for non-consequential load loss, or is it asking how much non-consequential load loss was being relied upon in the assessment? We recommend that the requirement be modified to require documentation of the maximum amount of non-consequential load loss that was relied upon during the assessment.

Response: The SDT does not think that in Requirement R2 replacing "prepare" with "conduct and document" would add clarity, since Requirement R2 includes requirement to document assumptions and results. No change made.

The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. No change made. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Part 2.1.2 requires that the Planning Coordinator and/or Transmission Planner also consider off-peak conditions because the System must be able to meet

Organization	Question 2 Comment

performance requirements over all demand levels. System peak condition may not represent all stressed conditions. For example, during off-peak, that Load is low, and the generation would have to be turned off to achieve Load-resource balance. Turning down resources within a Load area could result in reliability problems. Lowering the Load in areas with many non-dispatchable resources could also pose potential problems. As the System incorporates more and more renewable resources, some of them are non-dispatchable; a standard must be forward looking so the Planning Coordinator and Transmission Planner can identify potential problems as part of the Assessment. No change made.

Part 2.1.3 (now Part 2.1.4) has been rewritten to clarify the intent of the requirement. The requirement does not preclude a discussion of risk.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. The Planning Coordinator and/or Transmission Planner will need to decide which pieces of major Equipment in their respective Systems would be more vulnerable to long term outage. In Part 2.1.5 when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2 is intended to require a study performed in the current year, as opposed to studied performed in the past years. Part 2.2 has been revised to provide

Organization	Question 2 Comment

greater clarity.

> **2.2** The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6:

For Part 2.3 the decision on the year to be represented in the study is left to the discretion of the Planning Coordinator or Transmission Planner. Part 2.3 only requires it to be either study that was performed during the current year or in the past. For example, this year is 2009 and a study performed in 2009 is a current study, the study can investigate the System in a future year, which is at the discretion of the Planning Coordinator or Transmission Planner performing the study. Part 2.3 has been revised to provide greater clarity.

> **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.4.1 was not changed as proposed because the intent of the last sentence is to allow the use of an aggregated System Load model as an appropriate Load representation. The suggested change could be read to mean that an aggregated System Load model would not appropriately represent the dynamic behavior of Loads. Note that changes were made to Part 2.4.1 based on other stakeholder comments.

Parts 2.5 .1 and R2.5.2 (new Parts 2.6.1 and R2.6.2) were not combined. The references to the “20 MW” threshold have been deleted from the revised standard.

Part 2.6 has been modified and included as new Part 2.7. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur is more than one sensitivity). Although not required, the standard does not preclude the Planning Coordinator or Transmission Planner to develop Corrective Action Plans for high risk scenarios. However, if the scenario is high risk, then it should have been included in the base assumptions in the assessment and the Corrective Action Plan would have been required. The end of the second sentence has been changed to refer to Table 1 as suggested.

> **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Requirement R2, part 2.6.3 has been deleted.

Part 2.6.4 allows the Planning Coordinator or Transmission Planner to address situations that are beyond its control by utilizing Non-Consequential Load Loss and/or curtailment of Firm Transmission Service, which are normally not permitted. Depending on the urgency of the need, the Corrective Action Plan may be developed outside the normal Assessment cycle at the discretion of the Planning Coordinator or Transmission Planner involved. No change made.

Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

> **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

Organization	Question 2 Comment
Gainesville Regional Utilities	R2.1.1- References a "system peak Load" for each of the referenced years. Some utilities are summer peaking and some are winter peaking and others may have a history of having one or the other in any given year. So can you clarify which peak you are referring to or change to statement to perform studies involving both seasonal peaks? R.2.4.1- I suggest quantifying the reference to the behavior of induction motor loads to single motors greater than 1000 hp or multi motors at one bus totalling more that 2000 hp or so, since smaller induction motors probably will not have any significant impact of the BES. I feel this is best handled as a sensitivity issue determined by the PC who is familiar with this area. R2.5.1- If the system has not had any significant changes of the last ten years, then a study going back to that change should be acceptable for the assessment. R2.5.2- Should the "shall not include" really read as "shall include"? R2.6- The reference to "tables" in line 6 should be "table" since there is only a Table 1 in the standard. R2.6.1-R2.6.3- Question-- Why is the font size of the bullet text smaller that the other bullet segments?

Response: In Requirement R2, part 2.1.1, the selection of the system peak Load conditions is at the discretion of the Planning Coordinator or Transmission Planner. The standard allows for use of past studies to support a current Assessment. Therefore, for an area with both summer and winter peaks, the Planning Coordinator or Transmission Planner can choose to perform summer and winter peak cases on alternate years and the Assessment can rely on, e.g., a summer peak study performed in the current year and a winter peak study performed in the previous year, provided the requirement for use of past year studies is satisfied. No change made.

Part 2.4.1 allows for the use of an aggregate System Load model which represents the overall dynamic behavior of the Load that could impact the study area. So as written, the suggested representation is allowed. Note that changes were made to Part 2.4.1 based on other stakeholder comments.

Part 2.5.1 has been revised and included as Requirement R2, part 2.6.1 to address your concerns.

> **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

In Part 2.5.2 “shall not include” is correct because the intent is that for the past study to be applicable, the present System should not have changed materially compared to that represented in the past study. However, Requirement R2, part 2.5.2 has been revised and included as Requirement R2, part 2.6.2 in the new version to provide greater clarity.

> **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Part 2.6 (now 2.7) was modified to use the phrase, “in Table 1” rather than “in the tables.”

Part 2.5.1 (now 2.6.1) has been revised as shown.

> **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

Organization	Question 2 Comment
2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. For Part 2.6.1 (now 2.7.1) the format has been corrected. Parts 2.6.2 and 2.6.3 were deleted from the revised standard.	
JEA	R2.1.4 It is not clear if this spare equipment strategy excludes Generator Owner's obligations for their generation plant equipment and only includes Transmission Owner's equipment. It is also not clear what Measurable document is required to back up a position of no vulnerabilities. I recommend that we limit the spare equipment strategy to TO equipment and not include GO equipment which excludes step-up transformers, turbines, generators, rotors, etc.Also, it does seem unreasonable to assess the long-term loss of a transformer to the "Extreme Events" of Table 1 or any other event other than the P3 events unless substituted in the assessment by a more extreme and probable event. An event from P3 alone should be sufficient to expose a weakness of a spare equipment strategy based on historical industry statistics for such likelihood. Propose changing "The analysis shall reflect the Contingencies identified in Table 1..." to "An analysis shall be performed that as a minimum assesses the impact of the long term outage of Transmission Owner equipment under either a P3 event that could occur in the absence of the subject equipment" or a more stressful event as deemed appropriate by the Functional Entity performing the assessment. R2.6.4 First of all, some level of expected Non-consequential load loss is always prudent to balance customer expectations on cost and reliability subject to Local and State Authority's guidance. Second, load development and gneration development are the major drivers for transmission development needs. Generation plans are more dependable and manageable as to timing and impact. Load development is not very dependable and manageable relative to transmission system improvement needs. It is not unusual for new load forecast to either expose a transmission weakness or on the other hand to eradicate a transmission weakness in the Near Term horizon. Without guidance, it could be assumed that affects from load forecast are beyond the control of the Transmission Planner and Transmission Coordinator. In addition, it is not unusual to have the load forecast lead the generation plan by a few years causing a need for Non-Consequential Load Loss until such time the additional generation is in-service providing generation balance to the load area and mitigating the transmission improvement needs. This occurs frequently as generation development lags load development in fast growing communities. Propose establishing a cap on Non-Consequential Load Loss for all Corrective Action Plans where the Table 1 events currently do not allow at all. An additional option for the SDT to consider could be to add an allowance of lag time (maybe 4-5 years) to cover the gap while the generation addition is being developed.
Response: Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Transmission Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. However, the major Equipment is not limited to the major Equipment of the Transmission Owner; this standard covers major pieces of pieces of Transmission Equipment without regard to ownership. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. Requirement R2, part 2.1.5 has been revised to require that the analysis reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.	

Organization	Question 2 Comment
2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. For Part 2.6.4 (now 2.7.5), the SDT declines to set a cap on Non-Consequential Load Loss on situations that are outside the control of the Planning Coordinator or the Transmission Planner. The premise is that the Corrective Action Plan has already been developed, but was not able to be implemented in time. The situation can occur with both unexpected changes in generation, Load pattern or delay in permitting and construction of new Transmission Facilities. In addition, a cap on the allowable Non-Consequential Load Loss may be different for different areas and may not be practical in a Continent-wide standard. No change made.	
NorthWestern Corporation NorthWestern Energy (NWE) (NWMT)	Short circuit analysis is a local issue. The reliability of the BES does not depend on the regular assessment of short circuit duty. Therefore, we believe short circuit analysis should be deleted from R2. R2.1.4 needs more clarification as to what constitutes major Transmission equipment. This would require a separate analysis (study) for each transformer (or any long lead-time equipment) for which a spare is not available, which could result in numerous additional cases. Major Transmission equipment could be limited to voltage levels greater than 200 kV. An exception should be made for phase-shifting transformers. As the system changes, with new generation and transmission lines being added, these analyses could become outdated very quickly. If a transformer were to fail, the Planning Department would immediately study the current system with this transformer removed. As stated in R2.4.1, the requirement to include induction motor loads is too prescriptive. At this time, with all of the unknown or estimated variables in the system model, accuracy of the model would not be improved. If a highly industrialized section were to develop within the NWE footprint, induction motor load could be added to the system model. The 20 MW threshold identified as "material change" for generation in R2.5 is too small. A better number for material generation changes would be 100 MW or a limit based on a percentage of the study area's installed generating capacity. Also, an aggregate of 20 MW addition/deletion generation would depend on the location of the individual generators to determine whether the overall system would be affected or not. The statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement. R2.8 should be deleted. It is not necessary for reliability. R2.9 should be deleted. It is not necessary for reliability.
Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. Requirement R2, part 2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned	

Organization	Question 2 Comment
generation and Transmission Facilities in service which could impact the study area. Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.4.1 is intended to allow the Planning Coordinator and Transmission Planner the discretion in the use of Aggregated System Load models in Stability Studies, if specific models are not available. However, it does not dictate the methodology or the process on how the studies are to be done. No change made. Part 2.5 has been revised and included as requirement R2, part 2.6 as shown. Note that the references to the "20 MW" threshold were deleted from the revised standard. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Requirement R2, part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
SMUD	R2.1.3 and R2.4.3The sentence, "sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment: ", should be modified by changing the second 'included' to 'considered'. R2.1.4Since there is no NERC reliability standard requirement for a 'spare equipment strategy', what is the standing of a requirement that is based on having one R2.5.2There is no example given for 'Transmission additions/removals' Recommend that the wording of this requirement be made more discretionary with a requirement that the Transmission Planner include language explaining the reasons for using past studies.
Response: Parts 2.1.3 (now Part 2.1.4) and R2.4.3 have been revised. However, the SDT declines to change the work "included" to "considered" because the intent is that if the base case modeled already models the stressed condition, such as 1 in 10 adverse weather Load, even higher Load may not need to be included in the sensitivity study, **2.1.4** For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of	

Organization	Question 2 Comment
	changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance. • Real and reactive forecasted Load. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of planned Transmission outages. **2.4.3** For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance. • Load level, Load forecast, or dynamic model assumptions. • Expected transfers. • Expected in service dates of new or modified Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. The SDT has included the spare equipment strategy in Part 2.1.4 to ensure that the BES is designed so that it remains reliable even with long lead time Equipment unavailable, consistent with the directive from FERC Order 693. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. The SDT revised Part 2.5.2 (now Part 2.6.2) to remove the "Transmission additions/removals" and "generation changes" language.
Progress Energy Florida, Inc.	Concerning R2.1.4, this sub-requirement is overly burdensome for two primary reasons: a) It amounts to a system-wide N-2 and N-3 analysis, which goes against FERC's policy of separation and distinction between types of events as stated in Paragraph 1788 of Order 693: Under TPL-002-0 the system is not required to be able to withstand another N-1 contingency. That N-1 requirement is a Category C contingency which is addressed by TPL-003-0. b) The requirement to perform system-wide analysis for such a scenario is a significant workload issue, and will take time away from analysis of more probable events. Concerning the issue of material changes in past studies in sub-requirement

Organization	Question 2 Comment
	R2.5.2, PEF objects to the specification of changes in units of 20 MW or greater, due to the fact that a change (or even deletion) of a 20 MW unit in a case modeling a large BES does not truly constitute a material change. The SDT in its response to Question 15 in the comments for draft 2 stated that The SDT did not want to be overly prescriptive when describing the type of changes that could be considered material and has left the text general. PEF suggests that the SDT take its own advice, making the language in R2.5.2 more general in nature and leaving such modeling details to the discretion of the Transmission Owner. In R2.6.2, PEF assumes that the term "project initiation date" is intended to mean the Construction Move-In date. If the term means the first date at which Planners had identified it as a mitigation, PEF would object to this as it would appear to preclude the right to develop superior mitigations, or to cancel a project if it can be demonstrated as no longer needed. Concerning R2.8 and R2.9, PEF strenuously objects to such requirements. These requirements have no bearing on demonstrating the reliability (or lack thereof) of the BES, and therefore should be removed from the Standard.

Response: Part 2.1.4 (now Part 2.1.5) is based on FERC Order 693, Paragraphs 1724 – 1727. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the Planning Assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.5.2 has been revised and included as Requirement R2, part 2.6.2 to address your concerns. The revised standard does not include the reference to a "20 MW" threshold.

> **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Part 2.6 has been revised and included as Requirement R2, part 2.7 in the new version.

> **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Requirement R2, part 2.9 in he new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

Organization	Question 2 Comment
2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Xcel Energy	R2.1.3 is this indicating that only one of the variations need to be studied? ("in one or more of the following conditions"). Recommend having the planner work with the load to determine what sensitivity studies to perform. R2.1.4 it is unclear as to what should be done with the analysis that incorporates the company's spare equipment strategy. Is this requirement inferring that a company's spare equipment strategy need to ensure that it can still operate to within the requirements for contingencies of Table 1 without the component? R2.2.1 is the intent to have the study for the 10 year horizon or to include any project that is started within the next 10 years and thus the study must be extended to the forecasted completion of the project (conceivably as long as 20 years or more?) R2.6.4 recommend clarifying how situations beyond the control of the TP or PC are determined. It is unclear if this is to imply that if something is outside of the control of the department who conducts the planning studies or if it is outside the control of the registered function's legal entity (i.e. corporation). R2.8 appears to be nonessential information for reliability; for what purpose does this requirement exist? R2.9 - appears to be nonessential information for reliability; for what purpose does this requirement exist?

Response: Part 2.1.3 (now Part 2.1.4) does not preclude the Planning Coordinator or Transmission Planner working with other Functional Entities to develop strategies on performing sensitivity studies. Part 2.1.4 requires that the Planning Coordinator or Transmission Planner perform sensitivity studies for at least one of the variation not already covered in the studies described in Parts 2.1.1 and 2.1.2

Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreements with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead times longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standards in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line.

> **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the

Organization	Question 2 Comment
rationale for why that year was selected. Part 2.6.4 refers to the situations beyond the control of the Transmission Planner or Planning Coordinator as Functional Entities. Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as requirement R2, part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
New Brunswick System Operator	R2.1.4 Major transmission element needs to be defined. For example, what about sync condenser, or generator step up transformer R2.2 Clearity required. Example: What is meant by "current System peak load" It is not clear what supplemental load loss is. Would load tripped due to undervoltage or SPS as a result of a contingency be considered supplemental load? As a follow up what then is Non-consequential load (provide examples). How would this load be lost? The requirements appear the same regardless of the amount of Non-consequential load loss. Is there any consideration of applying thresholds both on suppmental and non-consequential load loss where these loads are defined as (or applied as) "exceeding xxx amount of MW". Regarding Table 1 b, what does the following mean: "However, Supplemental Load Loss associated with an event shall not be used to meet steady state performance requirements." Please clearify the definition of Year One. This definition also does not include Planning coordinator. Was that intentional?
Response: In Part 2.1.4 (now Part 2.1.5), major Transmission Equipment would be those pieces of Equipment, the loss of which can have significant impact on System performance. They are typically the ones listed in the Contingency Events in Table 1. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.2 refers to a "current System peak Load study". This would be a System peak Load study that is performed in the current year. In the Definition Section, Supplemental Load Loss is defined as Load that is disconnected from the network by end-user Equipment responding to post-Contingency System conditions. Because the disconnection is at the discretion of the Load customer, not the Planning Coordinator or Transmission Planner, they cannot be counted on to leave the System. Therefore, the Transmission System cannot be planned as if such Load would disconnect. Part 2.2 has been revised to provide greater clarity. **2.2** The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the	

Organization	Question 2 Comment
following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6: A cap on the allowable Non-Consequential Load Loss may be different for different areas and may not be practical in a Continent-wide standard. No change made. See response for Part 2.2 above. The definition has been revised to include Planning Coordinator. **Year One:** The first year that a Planning Coordinator or a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the end of the current calendar year.	
Lafayette Utilities System	R2.5. This basic requirement intends, as we understand it, to require that earlier studies not be used for a current assessment if they are no longer accurate. But the phrasing is potentially confusing, and would be clearer if revised. Since the requirement deals with the use of past studies, we suggest that R2.5.2 be revised to state that the study may be used only if there have been no material changes, so that R2.5 reads in full: R2.5. Past studies may be used to support the Planning Assessment if they meet the following requirements: R2.5.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less. R2.5.2. For steady state, short circuit, or Stability analysis: the study may be used only if there have been no material changes, such as generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability of 20 MW or greater. An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES which total 20 MW or greater. With respect to footnote 10 to Table 1, we fear that the flexibility suggested by those provisions may be excessive for a planning standard. The ambiguity occasioned by stating emergency actions that can properly be taken in a planning standard can be utilized by those who plan the system in a manner which plans to drop non-consequential loads just as footnote b has been used in the past. If this is intended to raise the bar as stated these provisions do not belong in a planning standard, at least as now stated. It may be appropriate to remove the reference to footnote 10, at least in the Initial System Condition entry in P3, where it suggests that it can be invoked after loss of a single generator, and we request the SDT to review that footnote to assure that it is appropriate in the other entries to which it is applied. In addition to the foregoing, we are concerned that the language of footnote 10 to Table 1 is unclear and subject to at least one interpretation that would seriously undermine reliability. Specifically, the first sentence of footnote 10 permits "[c]urtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources obligated to re-dispatch." The reference to an "obligat[ion] to re-dispatch" is ambiguous at best and should be clarified. For example, footnote 10 should not be read as permitting Balancing Authority A to rely on curtailment of firm transmission service coupled with re-dispatch of generation by adjacent Balancing Authority B during a Level 5 TLR event, based on the theory that, if a Level 5 TLR is declared and the Reliability Coordinator assigns to Balancing Authority B an NNL reduction responsibility that compels it to reload its resources, Balancing Authority B is therefore "obligated to re-dispatch" within the meaning of footnote 10. We suspect the intent of the first sentence of footnote 10 was to recognize and give effect to arrangements in which (following the example) Balancing Authority A has made a prior contractual arrangement with

Organization	Question 2 Comment
	Balancing Authority B (or another generation owner) to provide redispatch services when requested by Balancing Authority A. In that circumstance, Balancing Authority A would be allowed to couple the curtailment of firm transmission with redispatch provided by Balancing Authority B (or another generation owner) pursuant to its contractual obligation. We suggest that this limitation be reflected by revising the first sentence of footnote 10 to read as follows: Curtailment of firm transmission service, when coupled with the appropriate re-dispatch of resources subject to a contractual obligation to provide re-dispatch service to the operator of the system for which the Transmission Planner is responsible, is allowed both as a System adjustment (as identified in the column titled "Initial System Conditions") and a corrective action, where it can be demonstrated that Facilities remain within applicable Facility Ratings and those adjustments do not result in the shedding of any firm Load. Without the limitation reflected in the foregoing revision, an entity could interpret footnote 10 as allowing it to rely on the redispatch of generation by other systems that may be (in effect) mandated by a Reliability Coordinator during a Level 5 TLR event. That sort of "leaning" on adjacent systems should not be permitted as a System adjustment or corrective action under TPL-001, especially where it imposes uncompensated burdens and costs on the system(s) forced to redispatch under these circumstances.

Response: Part 2.5 has been revised and included as Requirement R2, part 2.6 as shown. Note that the revised standard does not include any reference to the "20 MW" threshold.

> **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.
>
> **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Footnote 10 (now footnote 9) was added to address the disjoint between how some parties calculate ATC/AFC when assessing Long Term Firm Transmission Service and the currently proposed TPL-001-1 standard. TPL-001-1 requires Transmission Planners to plan their systems to meet multiple contingency events and some parties assess Long Term Firm Transmission Service on a first Contingency basis. Units obligated to re-dispatch, as contemplated in Footnote 9 are those units which are contractually bound to provide the service as well as those obligated to provide the service under Network Integrated Transmission Service, under FERC's pro forma OATT. Under the pro forma OATT, units designated as network resources receiving NITS are obligated to re-dispatch as requested by the Transmission Provider pursuant to Section 33.2 to maintain reliability. The footnote is worded such that curtailment/re-dispatch cannot result in the loss of firm Load preserves the guidance given by FERC in Order 693 that no single Contingency result in the loss of firm Load. No change made.

The SDT has reviewed the application of footnote 10 (now footnote 9) and believes that it is correct. No change made.

Organization	Question 2 Comment
Mississippi Delta Energy Agency	R2.5. This basic requirement intends, as we understand it, to require that earlier studies not be used for a current assessment if they are no longer accurate. But the phrasing is potentially confusing, and would be clearer if revised. Since the requirement deals with the use of past studies, we suggest that R2.5.2 be revised to state that the study may be used only if there have been no material changes, so that R2.5 reads in full:"R2.5. Past studies may be used to support the Planning Assessment if they meet the following requirements: R2.5.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less. R2.5.2. For steady state, short circuit, or Stability analysis: the study may be used only if there have been no material changes, such as generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability of 20 MW or greater. An aggregated

Organization	Question 2 Comment
	addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES which total 20 MW or greater. With respect to footnote 10 to Table 1, we fear that the flexibility suggested by those provisions may be excessive for a planning standard. The ambiguity occasioned by stating emergency actions that can properly be taken in a planning standard can be utilized by those who plan the system in a manner which plans to drop non-consequential loads just as footnote b has been used in the past. If this is intended to raise the bar as stated these provisions do not belong in a planning standard, at least as now stated. It may be appropriate to remove the reference to footnote 10, at least in the Initial System Condition entry in P3, where it suggests that it can be invoked after loss of a single generator, and we request the SDT to review that footnote to assure that it is appropriate in the other entries to which it is applied.
Response: Part 2.5 has been revised and included as Requirement R2, part 2.6 as shown. Note that the revised standard does not include any reference to the "20 MW" threshold. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Footnote 10 (now footnote 9) was added to address the disjoint between how some parties calculate ATC/AFC when assessing Long Term Firm Transmission Service and the currently proposed TPL-001-1 standard. TPL-001-1 requires Transmission Planners to plan their systems to meet multiple contingency events and some parties assess Long Term Firm Transmission Service on a first Contingency basis.. Units obligated to re-dispatch, as contemplated in Footnote 9 are those units which are contractually bound to provide the service as well as those obligated to provide the service under Network Integrated Transmission Service, under FERC's pro forma OATT. Under the pro forma OATT, units designated as network resources receiving NITS are obligated to re-dispatch as requested by the Transmission Provider pursuant to Section 33.2 to maintain reliability. The footnote is worded such that curtailment/re-dispatch cannot result in the loss of firm Load preserves the guidance given by FERC in Order 693 that no single Contingency result in the loss of firm Load. No change made**.**	
Ameren	In R2, The phrase document results should be changed to summarize results. While results will be documented, the Planning Assessment should just include a summary. In R2.1, the reference to requirement R2.6 (at the end of the last line) should be changed to R2.5. In R2.1.3, it is suggested that the studies be referred to as the "base studies" to avoid confusion with the sensitivity studies. Also it is suggested that another phrase be added at the end for clarity. The entire R2.1.3 would then be as follows: For each of the base studies described in Requirements R2.1.1 and R2.1.2, sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the studies shall be included in the Assessment. Sensitivity studies would include changes to: In Requirement R2.1.4, it is suggested that language be added to reflect the possible unavailability of the equipment, such as: When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The analysis shall reflect the Contingencies identified in Table 1 during the conditions that

Organization	Question 2 Comment
	the System is expected to experience the possible unavailability of the long lead time equipment. It is not clear how adequate lead times for equipment would be determined. In Requirements R2.3 and R2.4, consider adding a reference to Requirement R2.5 for the past studies. In Requirement R2.4.1, it is suggested that it be reworded to the following: System peak Load for one of the five years, including Load models which appropriately represents the dynamic behavior of Loads, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable. Load models referenced in R2.4.1 should be confined to the consideration of transient stability study work. With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would cause needless work to be performed on those plants or areas of the system where no changes are occurring. We suggest adding the following to the end of R2.5.1: unless justification can be provided to demonstrate that the results of an older study are still valid. In Requirement R2.4.3, it is suggested that this sub-requirement be reworded to the following: For each of the base studies described in Requirements R2.4.1 and R2.4.2, sensitivity case(s) that are intended to stress the System with variations in one or more of the following conditions not already included in the base studies shall be included in the Assessment. Sensitivity studies would include changes to: In bullet three of Requirement R2.6.1, would we allow automatic generation tripping for a single (P1) event if it is not consequential? It seems that tripping of generation should be restricted to P2 events 2 or 3 at a minimum. In bullet five of Requirement R2.6.1, is there a maximum duration that operating procedures can be used before a capital project must be included (or completed) in the Corrective Action Plan? In Requirement R2.6.2, it is not clear what constitutes a "project initiation date". Please clarify. Please explain the reason why Requirement R2.8 is needed in the Assessment. Reporting the largest Consequential Load Loss does not impact reliability. Please explain the reason why Requirement R2.9 is needed in the Assessment. Reporting the largest Non-Consequential Load Loss doe not impact reliability. The proposed standard not only raises the bar for system performance requirements, but also raises the bar for reporting and documentation. We need to employ almost as many librarians and technical writers as engineers to develop and keep track of the documentation. Engineers need to spend more time performing the studies and spend less time documenting studies keeping track of documentation for multiple years.

Response: Part 2 has been revised to reflect your suggestion.

> **R2.** Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.

Organization	Question 2 Comment

In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

The SDT reviewed Part 2.1.3 (now Part 2.1.4) and declined to use the term "base study" because "base study" may have different meanings in different parts of the continent, and the term, "studies described in Parts 2.1.1 and 2.1.2" should be sufficient to avoid confusion. No change made.

Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Parts 2.3 and 2.4 have been revised to include the reference to the requirements for use of past studies.

> **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.
>
> **2.4** The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part2.6. The following studies are required.

Part 2.4.1 has been revised to reflect your suggestion. In addition, Part 2.4 concerns only "The Near-Term Transmission Planning Horizon portion of the Stability analysis". Part 2.4.1 carries the same limitation as Part 2.4.

> **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

The requirement has been revised as suggested.

> **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

The SDT reviewed Part 2.4.3 and declined to use the term "base study" because "base study" may have different meanings in different parts of the continent, and the term, "studies described in Parts 2.4.1 and 2.4.2" should be sufficient to avoid confusion. No change made.

Part 2.6 has been revised and included as Requirement, part 2.7 to reflect your suggestion.

> **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

The third bullet in Part 2.6.1 (now 2.7.1) is intended to meet the requirements in Table 1. Generation tripping is allowed at the discretion of the Planning

Organization	Question 2 Comment
Coordinator or Transmission Planner for P1 Events as long as there is no loss of firm Non-Consequential Load. In addition, in the fifth bullet, the duration for use of an operating procedure is also at the discretion of the Planning Coordinator or Transmission Planner because it may not be feasible environmentally to implement Transmission reinforcements in some locations. Project initiation date has been deleted from the requirements. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Requirement R2, part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Puget Sound Energy, Inc.	Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault). Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer. This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. The 20 MW threshold identified as material change for generation in R2.5 is too small. The limit should be raised or based on a percentage of the study area's installed generating capacity. R2.7 should be deleted, see comment on R2 above. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event? if it is documented? R2.9 should be deleted. It is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent, among other things, on the types of load being served. It very well may be a case by case situation.
Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. Part 2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.	

Organization	Question 2 Comment
Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. The language in Part 2.5.2 that referenced a 20 MW threshold was deleted from the revised standard. The SDT assumes that you meant the comment on short circuit analysis above. The SDT declines to delete the requirement as the SDT believes that it is a necessary part of an overall Planning Assessment. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed the both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Requirement R2, part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Manitoba Hydro	Requirement Text: R2.1: Reference of past studies should be to R2.5, not R2.6 (typo). R2.1.3: The sensitivity to Planned duration or timing of Transmission Outages should be modified to only include Planned long duration Transmission outages that span multiple seasons, if known. Short duration planned maintenance outages should not be included in a planning assessment. R2.1.4 - The second sentence doesn't read right - the sentence should be changed to read: "The analysis shall reflect the Contingencies identified in Table 1 under the conditions that the System is expected to experience during the unavailability of the long lead time equipment. R2.2.1 - This sub-requirement should be deleted. Why do extra assessments beyond the 10 year period" Any items beyond 10 years will be covered when they fall into the 10 year period. For example, if we assess the 10 year horizon, then the project due to be complete in 12 years will be part of the assessment in 2 years when it is 10 years out. We will have to show every year how our system meets compliance regardless of this extra analysis, so what's the point. Every year we have to show how we comply in the short and long term so what difference does it make when each project is completed as long as we are in compliance or identify Corrective Action Plans (CAPs) along the way. R2.4.1: The statement "a Load model shall be used which appropriately represents the dynamic behavior of Loads is not very crisp. What will appropriate be interpreted to mean by the NERC auditor? Does an MOD standard exist that covers gathering data and validating loads models? This should be a first step. The SDT should add a statement that the application of detailed induction motor modeling can be limited to areas where poor voltage recovery is expected due to a high concentration of such load. The requirement should be modified to require the PC/TP to provide a rationale for the load models used in its specific planning area. R2.5: A Past Study is a definition and should be moved to the definition section. The definition only identifies power changes

Organization	Question 2 Comment
	as possible material changes, but should also include machine control (exciters/governors) changes. We suggest the bulleted list of Material Generation changes be expanded. R2.6.1: Can the SDT clarify how a rate application qualifies as a CAP action? R2.9 - The sentence should refer to maximum Non-Consequential Load Loss not maximum permissible Non-Consequential Load Loss.

Response: In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

In Part 2.1.3 (now Part 2.1.4), outages that span multiple seasons are included in the last bullet, “Planned duration or timing of Transmission outages”. No change made.

Part 2.1.4 (now Part 2.1.5) has been revised to reflect your suggestion.

> **2.1.5** When an entity’s spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead times longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standards in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line.

> **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

Part 2.4.1 has been revised to provide greater clarity.

> **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

The SDT declines to move past study to the Definition Section because the Definition, once approved, will apply to all NERC Standards, however, past study is only used in this TPL Standard.

In Part 2.6.1, “rate application” refers to rate incentives to change behavior of end-use customers and can be part of the “actions to achieve required System performance”. This is included to allow for non-traditional solutions to achieving required System performance.

Part 2.9 has been deleted.

Organization	Question 2 Comment
E.ON U.S.	R2.1.3Change For each of the studies to For at least one of the studies R2.1.1 and R2.1.2 require that 3 studies be performed each year. As written, the requirement indicates that the transmission planner has to perform at least one sensitivity study for the 3 studies required by R2.1.1 and R2.1.2. This means that the transmission planner would also have to perform 3 or more sensitivity studies each year. One sensitivity study for one of the 3 studies required by R2.1.1 and

Organization	Question 2 Comment
	R2.1.2 should suffice. R2.1.4.Delete "The analysis shall reflect the Contingencies identified in Table 1 during the conditions that the System is expected to experience due to the unavailability of the long lead time equipment. This statement is redundant since R3 requires this analysis for all of R2.1. Including this statement in R2.1.4 and not in R2.1.1 and R2.1.2 makes it appear that this requirement has different performance requirements. R2.4.3R2.4 does not require studies annually. However, if the transmission planner chooses to study a System Peak Load or a System Off-Peak Load condition R2.4.3 requires that the planner also study sensitivity to that same condition in the current year. E.ON U.S. believes it sufficient that the assessment include a sensitivity study for some System Peak Load and some System Off-Peak Load condition.R2.6The third sentence should be modified to include R2.1.4., so that it reads "Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3, R2.1.4 and R2.4.3. The annual studies performed for Category P6 alert the Transmission Planner to the risks of transformer failure. The Transmission Planner is required to design the system to limit those risks. If the delivery time for a piece of equipment is 11 months, then P6 allows Interruption of Firm Transmission Service and Non-Consequential Load Loss. If the delivery time for a piece of equipment is 12 months, then P1 requires that the system be designed for no Interruption of Firm Transmission Service and Non-Consequential Load Loss. This is a significant increase in performance requirements for an event that will most likely not extend beyond to a second System Peak Load period. If R2.1.4 is not included in the requirement the transmission planners would essentially be designing for an Extreme Event, i.e., events which are more severe and have a lower probability of occurrence than Planning Events. R2.6.1Operating Procedures, by NERC definition, require significantly more detail than is appropriate for a Corrective Action Plan. It is not appropriate that Transmission Planners write Operating Procedures to be used by NERC Certified System Operators. E.ON U.S. suggests that Operating Procedures be changed to mitigation plans. R2.6.5 Planning Assessments and System Facilities are not NERC defined terms. Operating Procedures, by NERC definition, require significantly more detail than is appropriate for a Corrective Action Plan. It is not appropriate that Transmission Planners write Operating Procedures to be used by NERC Certified System Operators. E.ON U.S. suggests that Operating Procedures be changed to mitigation plans. R2.8There are no requirements to limit Consequential Load Loss. Impacted customers are typically aware of the customary level of service and have chosen not to pay for extraordinary levels of service. E ON US questions the purpose and benefit of this requirement. While continuity of service to end use customers is an important measure of service reliability for which utilities answer to state authorities, BES reliability requires that the system remain balanced and that local failures not result in cascading BES events NERC standards should, pursuant to FPA Section 215, focus solely on BES reliability

Response: Parts 2.1.3 (now Part 2.1.4) and 2.4.3: The SDT disagrees with changing Parts 2.1.4 and 2.4.3 to requiring sensitivity study for only one System condition because this change potentially could reduce the Assessment to be based on one sensitivity study on one System condition. Since the same sensitivity can have different impacts on System performance under different System conditions, and different System conditions may require different sensitivities to be investigated, such limitation may not be adequate to maintain reliability going forward. No change made.

Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Transmission Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service

Organization	Question 2 Comment
such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreements with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.6 is not intended for the Planning Coordinator or Transmission Planner to write Operating Procedures, only to reflect the effects or results of the Operating Procedures in its Corrective Action Plan. Mitigation Plan carries a special meaning for Compliance and so may not be appropriate for use in this standard. No change made. The term, "Planning Assessment" is one of several terms proposed for addition to the NERC Glossary of Terms Used in Reliability Standards. "System" and "Facilities" are already approved terms. Part 2.8 is intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed the requirement and agrees that as written it was unclear. Part 2.8 has been revised and included as Requirement R2, part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
LCRA Transmission Services Corporation	In R2.6.2, it is stated that a project initiation date is required as well as an in-service date. What is considered the project initiation date, the point at which the project plan is approved or the time at which construction is to begin? If it is the time at which construction is to begin, then LCRA TSC believes this requirement does not belong in the TPL-001-1 standard as the construction timeframe for a project is developed by groups outside of Planning based on resources and outage availability.
Response: Project initiation date has been deleted from the requirements.	
National Grid	R2 Comment In the first sentence, replace the phrase prepare with conduct and document and in the second sentence replace "This Planning Assessment shall use current or past studies, document assumptions, document results, and shall cover steady state analyses, short circuit analyses, and Stability analyses" with "The Planning Assessment shall review assumptions of current or past studies and assess the continuing validity of the steady state, short circuit, and stability results. The review of assumptions, supplemental analysis, and updated results shall be documented. R2.1 Comment A. The terms assess and annual study are referenced in the same requirement. It is unclear what constitutes either. Is an annual study required for every area or is an annual assessment required for every area, which may include some supporting study to address changes to the conditions? B. Requirement R2.1 should refer to R2.5 rather than R2.6 R2.1.1 Comment A. Year One and year two do not provide enough time to implement Corrective Action Plans and are better

Organization	Question 2 Comment
	suited for Operations studies. The requirement to evaluate Year One or year two should be removed. B. Is a year 5 study required annually for every area of a system? R2.1.2 Comment ? The requirement should be removed. With no description of the system stresses and generator outages to be applied when assessing the off-peak load, it is difficult to imagine any issues which would arise which are not revealed in the peak load evaluation that could not be addressed through generation dispatch adjustments. Need to define conditions for assessment. R2.1.3 Comment A. The emphasis on sensitivity testing in the existing section appears misdirected and should be focused on the expected accuracy of the assumptions. The assessment should have to include a discussion of accuracy of the assumptions. Having a requirement to perform one more sensitivity not already included is vague and does not add value to the assessment or the standard. B. Planned Transmission Outages are not known in the Planning horizon. Also the release of the outage on any given day is controlled by operations based on the conditions. The conditions are not known for the Planning assessment. The last bullet referring to Planned Transmission Outages should be deleted. C. Delete the phrase "are intended to." It is difficult to measure intent and what is important is whether the system has been stressed, not whether the responsible entity intended to stress the system. D. What is expected from a sensitivity analysis? Is it to change the base case and see how the case responded, is it to create a new base case and rerun all of the events, or is it to change the base case and rerun a select number of events. It is anticipated that the answer will vary based on what is changed. R2.1.4 Priority Comment With respect to spare equipment strategy; this requirement potentially imposes a requirement to plan for three events, which is overly severe. After experiencing a major contingency of a long lead time facility, there should be some change in the acceptability of risk. This change in risk could include an allowance for the loss of non-consequential load or some of the multiple events from Table 1 should be evaluated as Extreme Contingency events. R2.2 Comment We suggest replacing the phrase a current System peak Load study? with a valid System peak Load study in the first sentence. The word current is confusing as some read the word current to mean today's rather than valid. R2.3 Comment A. The requirement to conduct annually isn't consistent with support. We suggest Conducted annually should be replaced with the phrase assessed annually?.B. "Interruption duty" should be changed to "interrupting duty." All terms in the IEEE dictionary related to breaker opening use the word "interrupting," while terms related to loss of supply to customers use the word "interruption." R2.4.1 Comment A. The two sentences are describing an or condition and they should be merged to read: For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.4.3 Comment - Delete the phrase "are intended to." It is difficult to measure intent and what is important is whether the system has been stressed, not whether the responsible entity intended to stress the system.

Organization	Question 2 Comment
	R2.5 Comment If past studies only support, then a new study is still required. We suggest changing “Past studies may be used to support the Planning Assessment if they meet the following requirements:” to “Past studies may be used to fulfill all or a portion of the Planning Assessment provided they meet the following requirements:” Violation Severity Levels:R2 - There is no VSL associated with R2.5. A VSL should be added, perhaps under Moderate, that "past studies were utilized to fulfill all or a portion of the requirement, but the studies did not meet the requirements in R2.5." R2.5.1 Comment? We suggest deleting this requirement, and incorporating it into R2.5.2.R2.5.2 Comment To incorporate R.2.5.1 into R2.5.2; please modify the section as follows: For steady state, short circuit, or stability analysis the study shall be less than five calendar years old from the date of completion. The present System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. A material change does not require the whole study to be redone. It only requires that the affected portion of the study be reassessed. Material generation changes include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. “ An aggregated addition/deletion/change to a group of generating units directly connected to the BES at one point of interconnection through one or more transformers and determined to be material by the Planning Coordinator or Transmission Planner. The reference to the step-up transformer may not capture a wind farm that could have transformers to step-up to a collection voltage and transformer that wouldn’t be labeled a GSU to connect to the system. R2.6 Priority Comment A. As written, this section undermines the value of the sensitivity testing. This section should require a corrective action plan to fix problems determined in sensitivity analysis if there is a reasonable risk of occurrence. We suggest making the standard read Provide documentation that explains the reasoning for the sensitivities considered and selected. B. At the end of the second sentence, the phrase in the tables” is used. We suggest using more definitive language such as in Table 1. R2.6.1 Comment -In the last bullet, the reference to "rate application" is unclear. R2.6.2 Comment The phrase Project Initiation Date needs to be defined. It is unclear if this is the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase as well as an in-service date should be modified to read as well as a target in-service date. R2.6.3 Comment Plans can provide a target in-service year, but not an actual in-service year. R2.6.4 Priority Comment There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year’s assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient time to incorporate this into that year’s assessment and develop corrective actions. R2.7 Comment A. "Interruption duty" should be changed to "interrupting duty." All terms in the IEEE dictionary related to breaker opening use the word "interrupting," while terms related to loss of supply to customers use the word "interruption."B. The requirement would be clearer if it we restructured as follows: "For short circuit analysis, if the short circuit interrupting duty determined in Requirement R2.3 exceeds the Equipment Rating of fault interrupting devices, the Planning Authority . .

Organization	Question 2 Comment
	." R2.8 Comment A. Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. B. If it is not deleted, do we have to prepare one number for P1 and a separate number for P2? The phrase any P1 event and any P2 event in Table 1 could also be read as the worst loading for each event within P1 and P2, which could be hundreds of values depending on how many events are analyzed. We recommend that the requirement be modified to require documentation of the maximum amount of consequential load loss that was relied upon during the assessment of the P1 and P2 events.C. If it is not deleted, "shall provide" should be changed to "shall identify" for consistency with R2.9 R2.9 Comment A. Largest consequential load loss is not factored into the Planning Assessment and should therefore be deleted. B. If it is not deleted, this requirement is unclear. Is this requirement asking for each transmission planner to list their criteria for non-consequential load loss, or is it asking how much non-consequential load loss was being relied upon in the assessment? Including the word “permissible” implies the responsible entity must decide how much Non-Consequential Load Loss is allowed. We recommend that the requirement be modified to require documentation of the maximum amount of non-consequential load loss that was relied upon during the assessment of the P1 and P2 events.

Response: The SDT does not think that in Requirement R2 replacing “prepare” with “conduct and document” would add clarity, since Requirement R2 includes requirement to document assumptions and results. No change made.

In the Definition Section, Planning Assessment is defined as “Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies”. Therefore, in Part 2.1, an Assessment is an evaluation of System performance based on studies performed. While an Assessment is required annually, it can be based on past studies as long as the requirement for a valid past study is met. As such, all studies used to support the Assessment do not have to be preformed annually. No change made.

In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

For Part 2.1.1 Year One and year two are within the Planning Horizon. In the Definition Section, Year One is defined as “The first year that a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the current calendar year”. Operating Studies are performed for system conditions within 12 months of the current calendar year. No change made.

Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the Near-Term Transmission Planning Horizon: (1) A Year five case to identify potential problems that can be addressed if the planned projects proceed as scheduled; (2) A Year one or Year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. The standard provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment and to assess other years in addition to those identified in Part 2.1.1. No change made.

Part 2.1.2 requires that the Planning Coordinator and/or Transmission Planner also consider off-peak conditions because the System must be able to meet performance requirements over all demand levels. System peak condition may not represent all stressed conditions. For example, during off-peak, the Load is low and the generation would have to be turned off to achieve Load-resource balance. Turning off resources within a Load area could result in reliability problems. Lowering the Load in areas with many non-dispatchable resources could also pose potential problems. As the System incorporates more and more renewable resources, some of them are non-dispatchable; a standard must be forward looking so the Planning Coordinator and Transmission Planner can identify potential problems. If studies for one of the Load periods are not needed annually, the Planning Coordinator or Transmission Planner can rely on past studies for the

Organization	Question 2 Comment

Planning Assessment. No change made.

Part 2.1.3 (now Part 2.1.4) has been rewritten to clarify the intent of the requirement. The Planning Coordinator or Transmission Planner can include a discussion of accuracy of the assumptions in response to the new Part 2.7.2 on the actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

2.7.2 Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

The last Bullet in Part 2.1.3 (now Part 2.1.4) is intended to cover planned outages of Facilities in sensitivity studies if such planned outages are known at the time the planning studies are performed, for example, planned outage of a major Transmission line during construction if the Corrective Action Plan calls for rebuilding of the line to a higher operating voltage. The sensitivity study can cover the "what if" situation where the project start can be delayed or the project may take longer to construct. No change made.

Part 2.1.3 - 'Are intended to' has been deleted.

The SDT declines to make the change as suggested. A Planning Assessment is not the same as a study. As stated in the Definition, a Planning Assessment is a "documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies". As such, a Planning Assessment is based on a number of studies from which to draw conclusions about System performance and to develop Corrective Action Plans where needed. The suggested change would necessarily imply that a study is the same as a Planning Assessment, which is not the intent of Part 2.3.

Part 2.1.4 (now Part 2.1.5) is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to address some of your concerns. Part 2.1.4 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or

Organization	Question 2 Comment
	more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2 is intended to require a study performed in the current year, as opposed to studies performed in the past years. Part 2.2 has been revised to provide greater clarity.

2.2 The Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, part 2.6:

Part 2.3 has been revised to provide greater clarity.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

Part 2.4.1 was not changed as suggested because the intent of the last sentence is to allow the use of an aggregated System Load model as an appropriate Load representation. The suggested change could be read to mean that an aggregated System Load model would not appropriately represent the dynamic behavior of loads. However, Part 2.4.1 has been revised to provide greater clarity.

2.4.1 System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Part 2.4.3 has been revised to provide greater clarity, and the phrase, “are intended to” is no longer used.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Load level, Load forecast, or dynamic model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

As revised Part 2.1.3 (now Part 2.1.4) requires the use of sensitivity studies to “demonstrate the impact of changes to the basic assumptions used in the model”. To this end the sensitivity studies need only to be able to demonstrate the impact of changes. Typically, a sensitivity study would be a subset of the study already performed. It usually involves comparing the base cases with and without the change under consideration, and rerunning a list of the worst Contingencies. However, each situation is different and the specifics are left to the Planning Coordinator or Transmission Planner who are more familiar with the situation(s) to be

Organization	Question 2 Comment

investigated.

Part 2.5 (now Part 2.6) was not changed because studies, including past studies, are used to support the annual Assessment, and are not used to support current studies.

The VSL for Part 2.5 (now Part 2.6) was added as a Lower VSL.

R2, Lower VSL: The responsible entity failed to comply with Requirement R2, part 2.9 or Requirement R2, part 2.6.

Parts 2.5.1 and 2.5.2 (new Parts 2.6.1 and 2.6.2) were not combined; however, they have been revised to address your concerns.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Part 2.6 has been modified and included as new Part 2.7. The intent is to allow discretion for the Planning Coordinator or Transmission Planner to correct those deficiencies if they are prevalent (i.e., occur is more than one sensitivity). Although not required, the standard does not preclude the Planning Coordinator or Transmission Planner to develop Corrective Action Plans for high risk scenarios. However, if the scenario is high risk, then it should have been included in the base assumptions in the assessment and the Corrective Action Plan would have been required.

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Part 2.6 has been modified and included as new Part 2.7

In Part 2.6.1, “rate application” refers to rate incentives to change behavior of end-use customers and can be part of the “actions to achieve required System performance”. This is included to allow for non-traditional solutions to achieving required System performance.

Part 2.6.3 - Project initiation date and in service date are no longer used in the requirements.

Part 2.6.4 allows the Planning Coordinator or Transmission Planner to utilize Non-Consequential Load Loss and/or curtailment of Firm Transmission Service, which are normally not permitted to address situations that are beyond its control. Depending on the urgency of the need, the Corrective Action Plan may be developed outside the normal Assessment cycle at the discretion of the Planning Coordinator or Transmission Planner involved.

Part 2.7 has been revised and included as Requirement R2, part 2.8 to reflect your suggestion.

2.8 For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

Organization	Question 2 Comment
Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed the both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Requirement R2, part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Entergy Services, Inc	The "study area" referred to in R2.3 should be defined. Does it mean external contingency events should be evaluated, or, the effects of internal contingency events on external parties. It should be clarified that generating facilities are not included in R2.1.4. The strategy may include agreements to share spare equipment among facilities, generation owners, and transmission owners. In R2.6.4 what is "prudent"? Who decides what is prudent? Recommend that the word be stricken. R2.6.4 is in conflict with the Implementation Plan. The Implementation plan omits P1 as an event where the bar has been raised but R2.6.4 allows the use of non-consequential load and firm transmission service curtailment. Clearly, the bar has been raised for any event, including P1, which allowed the curtailment of non-consequential load or firm transmission service in the existing standard. In R2.9 is the team requiring that a criteria be set by each Transmission Owner to set a maximum level of non-consequential load loss allowed by that Transmission Owner, or, that the amount of non-consequential load curtailment needed to meet the requirement be documented? What is the rationale for being so prescriptive in requiring specific years to be studied in R2.1.1 Why not allow the TP and/or PC to decide on the three years to be studied in the Near Term?? In the subrequirements of R2.1.3 and R2.4.3, the use of the word timing is unclear. Consider using in service date or “schedule for”. R2.1.4: The spare equipment strategy is too severe. The requirement should take into consideration the probability of occurrence of the events. Losing a transformer followed by the loss of a generator and a second transmission element is very unlikely. Non-consequential load loss should be allowed for this type of analysis. With the elimination of the distinction between system and generating plant stability studies, the blanket requirement in R2.5.1 that all stability analyses be five calendar years old or less, regardless of any material changes to the system, would cause needless work to be performed on those plants or areas of the system where no changes are occurring. Recommend adding the following to the end of R2.5.1: unless justification can be provided to demonstrate that the results of an older study are still valid. In R.2.4.1 it is mentioned that an aggregate System Load model that represents dynamic behavior of the load is acceptable. Does it mean that load at every bus in the study area has to be represented with an aggregate load model? This could be very cumbersome effort and we are not sure whether the software program can handle this magnitude of dynamic data. To help address this, revise Load to be Load that could impact the study area is acceptable. In Requirement R2.6.2, please clarify the definition of "project initiation date". Please explain the reason why Requirement R2.8 is needed in the Assessment and how does reporting the largest

Organization	Question 2 Comment
	Consequential Load Loss impact reliability?? Please explain the reason why Requirement R2.9 is needed in the Assessment and how does reporting the largest Non-Consequential Load Loss impact reliability?? Please clarify the use of the word permissible in the phrase “maximum permissible Non Consequential Load Loss”.

Response: In Part 2.3 because the area that can be impacted is not confined to Facilities ownership, the study area should therefore include all Facilities that can reasonably be impacted. Where the study area involves several owners, coordination is required. However, since short circuit analysis is usually a localized issue, the area impacted would not be extensive.

Part 2.1.4 (now Part 2.1.5) refers to “unavailability of major Transmission equipment” without regard to ownership. Also, Part 2.1.5 only requires a spare equipment strategy but does not dictate the details of that strategy. So sharing of spare equipment is allowed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

> **2.1.5** When an entity’s spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.6.4 has been revised to address your concerns and the word, “prudent” was removed.

The Implementation Plan has been revised to include certain P1 events where the bar is being raised.

Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the near-term planning horizon: A Year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled. A Year one or Year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. The standard provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment and to assess other years in addition to those identified in Part 2.1.1.

Parts 2.8 and 2.9 were intended to contribute to open and transparent transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

> **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

Part 2.1.3 (now Part 2.1.4) and R2.4.3 have been revised to reflect your suggestion.

> **2.1.4** For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

Organization	Question 2 Comment
	• Real and reactive forecasted Load. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of planned Transmission outages. **2.4.3** For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance. • Load level, Load forecast, or dynamic model assumptions. • Expected transfers. • Expected in service dates of new or modified Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. Part 2.4.1 has been revised to address your concerns. **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable. Part 2.5 has been revised and included as Part 2.6. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Part 2.6.2 was removed.
Great River Energy	R 2.1, 2.3, and 2.4 need consistency. 2.1 says "The Near-Term Transmission Planning portion of the Steady State analysis..." 2.3 says "The short circuit portion of the Planning Assessment ... addressing the Near-Term Planning Horizon..." 2.4 says "The Near-Term Transmission Planning portion of the Stability analysis..." These three sentences confuse the order. As I understand the Planning Assessment has two parts, a Near-Term portion and a Long-Term portion. Each of those parts has three components, a Steady state component, a Short Circuit component, and a Stability component. I

Organization	Question 2 Comment
	believe the standard's language should be structured as such. R2.1.3- The last bullet would seem to indicate that planners have the capability of predicting the future. The statement would seem to fit more in an operating standard. A suggested revision would be: Known long-term transmission outages with duration greater than one year R 2.1.4 addresses the spare equipment strategy. What is the scope of this sensitivity? Is the intent to do only a full steady state analysis with regard to long lead time spares? R2.6.2 would seem to be placing the planner again in the capability of predicting the future. Coming up with specific dates based on budgets, projected growth rates, potential permitting issues, and material delivery schedules would make it difficult to define an initiating date and an in-service date. An in-service season and year may be more applicable in a planning study for near-term projects. GRE is not sure why an initiating date is of relevance in an assessment.

Response: In the third posting, the Standard, as proposed, requires steady state, Stability and short circuit analyses for the Near-Term Transmission Planning Horizon; steady state for the Long-Term Transmission Planning Horizon. In the fourth posting, the SDT proposes to add Stability analysis to the Long-Term Transmission Planning Horizon. So the requirements are not the same as you described. However, the Requirements have been revised to provide greater clarity.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4 The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part2.6. The following studies are required.

The last Bullet in Part 2.1.3 (now Part 2.1.4) is intended to cover planned outages of Facilities in sensitivity studies if such planned outages are known at the time the planning studies are performed, for example, planned outage of a major Transmission line during construction if the Corrective Action Plan calls for rebuilding of the line to a higher operating voltage. The corresponding sensitivity could simulate unplanned delay starts or unplanned extension of construction period. No change made.

Part 2.1.4 (now Part 2.1.5) is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. As such the analysis is not limited to steady state studies. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Parts 2.6.2 and 2.6.3 have been removed since the definition of Corrective Action Plan already includes "timetable for implementation".

Organization	Question 2 Comment
BC Hydro	Comments: Consider changing the second sentence to read, This Planning Assessment shall use current or past studies, document assumptions, document results and shall cover all analyses needed to clearly demonstrate that the proposed system expansion plan meets all planning criteria and standards. This standard should not limit the studies to only steady state analyses, short circuit analyses and Stability analyses none of which seem to be defined anywhere. In some cases it would be appropriate for planning studies to cover analyses of such phenomenon as electromagnetic transients, sub-synchronous resonance, ferroresonance and harmonics. The fact that Stability is capitalized suggests that it refers to the definition of Stability in the NERC glossary, but that definition reads just, The ability of an electric system to maintain a state of equilibrium during normal and abnormal conditions or disturbances?, but stability analyses (often more properly termed dynamic simulation studies) usually encompass more than simply electromechanical or voltage stability. Usually voltage and frequency excursions are also analyzed and perhaps temporary overcurrent also (eg, assessing temporary overvoltage levels across series capacitor banks).
Response: Even though the other types of studies as identified are important for specific cases, a NERC Standard needs to be applicable continent-wide. The modification could require the inclusion of studies such as EMTP, long-term stability, etc., in the annual Planning Assessment, which is not necessary in all cases. No change made.	
Midwest ISO	Opening Remarks. Specific Comments for Requirement 2:A) Under R2, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R2 only says Long-term Planning. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: Near-Term and Long-Term Transmission Planning. B) Under R2.1 there is a reference to qualified past studies in R2.6. We believe that this reference should be pointing to R2.5 not R2.6. C) Under R2.1.3 there is ambiguity in the third bullet language new or modified Facilities and we believe that this language should mimic that of R1.1.2 in order to improve this requirement. The third bullet should read: Timing of the installation of new Planned Facilities or changes to existing Facilities. D) Under R2.1.3 there is ambiguity in the fourth bullet language capability and we believe that this language should read: Reactive resource capability (Generator, STATCOM, SVC, other?etc). We believe that this language addition improves this requirement. E) Under R2.1.3 there is ambiguity in the seventh bullet language Transmission outages and we believe that this language should read: Planned duration or timing of specifically scheduled or planned for Transmission outages. This language mimics similar language suggested above in R1.1.1 (letter C on page 3 of 9) F) When a spare equipment strategy does not cover the long lead time unavailability as stated in 2.1.4, will the system be treated as “normal system condition and Table 1 requirements or as having a contingency from which system adjustments are to be made prior to subsequent events. We believe that this task will be burdensome for large entities such as RTOs and we are not clear on the benefit that this requirement brings. For example: If in an RTO system where a party has spare equipment, how can the RTO ensure that a spare part from one asset owner can be made available to other asset owners”

Organization	Question 2 Comment
	G) Under R2.2 a System peak load study is required annually for one of the years in the assessment period. R2.2.1 requires the assessing entity to extend their planning assessment to accommodate any known longer lead time projects that may take longer than ten years to complete. It does not make sense to study the ten year horizon, find a problem in year ten which has a solution that required twelve years to build. For compliance with this standard, you would need to find another solution that can be built within ten years as opposed to the suggested language in R2.2.1 of extending the planning assessment beyond ten years to accommodate the solution that falls outside of the Long-Term Planning Horizon. No project solution greater than 10 years should be acceptable because it falls outside the Long-Term Transmission Planning Horizon. Suggestion to strike sub-requirement R2.2.1 from this standard. H) Under R2.3 the second sentence requires that "The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with any generation and Transmission Facilities in service which could impact the study year". We suggest changing the language to read: The analysis shall determine the maximum short circuit interruption duty on fault interrupting devices using the System short circuit model with Planned Facilities in service which could impact the study year". The definition of Planned Facilities was suggested to be added in the comment above in R1.1.2 under letter (E). I) Under R2.4 the second sentence requires states The following studies are required. We suggest changing the language to read: The following current studies are required. We believe that this language addition improves this requirement. J) Under R2.4.1 the first sentence leaves to much ambiguity as to who determines whether severity of system peak or off peak as well as whether the system load levels appropriately represents the dynamic behavior of loads. If the monitoring agency wishes to make this determination than it should be explicitly written here in this requirement. If the assessing entity is to make this determination than we offer the following language suggestion that we feel will improve this requirement. "For one of the five years, the more severe System peak or off peak System load level, as judged by the assessing entity, shall be used which in the judgment of the assessing entity appropriately represents the dynamic behavior of Loads including consideration of the behavior of induction motors". K) For R2.4.2, we suggest striking this requirement altogether and add System Off-Peak to R2.4.1 above in R2.4.1 under letter (I). L) Under R2.4.3 there is ambiguity in the third bullet language new or modified Facilities and we believe that this language should mimic that of R1.1.2 in order to improve this requirement. The third bullet should read: Timing of the installation of new Planned Facilities or changes to existing Facilities. M) Under R2.4.3 there is ambiguity in the fourth bullet language capability and we believe that this language should read: Reactive resource capability (Generator, STATCOM, SVC, other etc). We believe that this language addition improves this requirement. N) The sub requirement R2.5.2 states that for steady state, short circuit, or stability analysis; the present System model shall not include any material changes, such as..etc. The present language in this section is vague and requires discretion on the part of both the Transmission Planner and the Planning Coordinator performing the assessment. For example, new transmission enhancements may have been added since the previous System model was developed. In general, such topology enhancements will only improve reliability and would not necessitate re-assessment with a newly updated System

Organization	Question 2 Comment
	model. In addition, any significant generator additions would have been evaluated with a full separate generator interconnection study at which the full reliability of the System would have been taken into consideration. For this reason, we believe the following language for R2.5.2 would improve this requirement: For steady state, short circuit, or Stability analysis: the current System model of the assessed plan year shall not include any changes material to the assessment, as judged by the entity performing the assessment, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study year. Material generation changes could include: O) Under R2.6.1 the fifth bullet regarding the use of Operating Procedures needs to be made clearer. We believe that the following language will improve this requirement: Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan. Operating Procedures may not include Non-Consequential Load Loss when not permitted in Table 1. P) Under R2.6.1 the sixth bullet regarding the use of rate applications, DSM, new technologies or other initiatives can be improved with the following language additions: Use of rate applications, DSM, new technologies or other demand side initiatives can be improved with the following language additions. Q) Under R2.6.2 the language regarding project initiation date is vague. We suggest the following definition to be added to this standard and further added to the NERC Glossary of Terms: Project Initiation Date A date in which Planned Facilities are expected to break ground. R) Under R2.8 please add a coma between the words event and caused. A PC/TP would study multiple P1 and P2 events involving consequential load loss not just the largest. Unless the SDT has a measure in mind for consequential load loss, this requirement should be removed. S) Under R2.9 please strike the word permissible and replace with necessary. It is not clear what the SDT is requesting with this requirement.

Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.

Organization	Question 2 Comment

- **Operations Assessment** — follow-up evaluations and reporting of real time operations

In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made

Part 2.1.3 (including the third and seventh bullets) (and now Part 2.1.4) has been revised to provide greater clarity. The SDT declines to change the fourth bullet because adding a partial list of devices that could provide reactive resources may not improve clarity beyond the present description.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

Part 2.1.4 (now Part 2.1.5) requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. Perhaps it would help if sharing major Equipment can be part of an operating agreement within entities belonging to the RTO; however, that would be outside the scope of this Standard. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead time longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standard in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line.

2.2.1 A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the

Organization	Question 2 Comment

rationale for why that year was selected.

Part 2.3 has been revised to reflect your suggestion.

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

In Part 2.4.1, the SDT was not able to locate the reference to the comment on the "ambiguity as to who determines whether severity of system peak or off peak". No change made.

Part 2.4.1 has been revised to provide greater clarity. However, the SDT declines to modify Part 2.4.1 to require study for "the more severe System peak or off peak System load level" for one of the five years in the Near-Term Transmission Planning Horizon because the System needs to meet performance requirements under all System conditions including peak and off-peak. In addition, the Planning Coordinator or Transmission Planner can rely on past studies as provided in Part 2.5 (Part 2.6 in the new version). For this reason Part 2.4.2 has been retained.

2.4.1 System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Part 2.4.3 (including the third bullet) has been revised to provide greater clarity. The SDT declines to change the fourth bullet because adding a partial list of devices that could provide reactive resources may not improve clarity beyond the present description.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Load level, Load forecast, or dynamic model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

Part 2.5 has been revised and included as Part 2.6.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Part 2.6.1 has been revised and included as Part 2.7.1 to provide greater clarity. However, the SDT declines to include "Operating Procedures may not include Non-Consequential Load Loss when not permitted in Table 1" because it is redundant. Part 2.6.1 (now Part 2.7.1) is a sub-part of Part 2.6 (now Part 2.7), which

Organization	Question 2 Comment
explicitly requires meeting the performance requirements in Table 1. Parts 2.6.2 and 2.6.3 have been removed since the definition of Corrective Action Plan already includes “timetable for implementation” so a new NERC definition is not required. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
PJM	In R2, why require a Planning Coordinator AND a Transmission Planner to perform this analysis? Isn’t this a duplication of effort? In R2, I have always heard that dynamics studies are performed to determine Stability. In R2.1, need to update reference to R2.6 from R2.5. In 2.1.1 and R2.1.2, is this annual peak or seasonal peak? Summer peak for summer peaking entities and winter peak for winter peaking entities or both summer and winter peak for all entities. R2.1.1 year one or two studies should be only required as operating studies. By their nature, the upgrades or fixes that could be accomplished in this time frame are limited to short lead time fixes. These analyses are needed to determine how to accommodate construction schedule deviations and near term system issues that may cause issues. Traditional Planning studies will be of no benefit in this timeframe. Change the requirement to be a study for year 3,4 or 5 with updates for material changes that occur when a previous year study is still within this time frame.R2.1.2 and R2.1.1 should be combined and the TP should assess and justify its choice of the critical load scenarios to analyze. Concerned about the extent of variations required in R2.1.3. Like would I have to vary all proposed generator in-service dates? Just a couple? One? Requirements need to be clear or compliance will assume the largest scope possible. Also in R2.1.3, first bullet words should align with the words of R1.1.3. Also in R2.1.3, second bullet words should align with words of R1.1.4 and R1.1.5. Also in R2.1.3, third bullet, modified facilities are not installed, suggest changing -installation to -availability--. Also in R2.1.3, fifth bullet, suggest moving retirements-- up to third bullet and dropping -- Generation additions, retirements, or other-- leaving just dispatch scenarios R2.1.4 should be deleted. There are no NERC requirements on spare equipment availability and this requirement seems like a backhanded way to include such a requirement. R2.2.1 should be reworded because it now requires everyone to extend their studies. Suggest If planned projects will take longer than ten years to complete, the Planning Assessment shall be extended accordingly- R2.4.1 Not sure I understand. The second sentence and the third sentence seem to be in conflict

Organization	Question 2 Comment
	R2.4.2. This requirement has lost significance with the deletion of unit stability. Off-Peak scenarios are critical for unit stability and analysis of pockets of known light load stability sensitivity. This requirement should not be worded to require a general system off-peak stability study since this will not provide useful information. The requirement should be reworded to clarify that the TP should identify its critical off-peak stability sensitivities and provide annual stability analyses that address the system's off peak stability issues.R.2.4.3 should only refer to R2.4.1 since R2.4.2 are sensitivities themselves. In R2.4.3, first bullet, how would load model assumptions be varied? Same comments on bullets here as R2.1.3 above. R2.5.2 is impossible to judge. Material changes needs to be defined. The word could in the sentence before the bullets makes them useless as a definition. By trying to define material changes the SDT has created a situation where, for large interconnection, it would be virtually impossible to use a past study. The addition of a 100 MW generator two states removed from the study area would not be considered material but by the guidelines in this requirement it can be interpreted as such. R2.5.2 Add that retools of past studies that address the local impacts of specific cumulative material changes that occur are sufficient to continue to support current planning assessment. R2.6 has a mixing sigular and plural tenses. What if only one problem is found and therefore only one Corrective Action Plan is needed. Or can one Plan cover all the problems found? Responses to R2.8 and R2.9 would be considered Critical Energy Infrastructure Information (CEII) and that should be noted so it can be protected. R2.8 and 2.9 change to read that the Planning Coordinator will provide its criteria for load loss that is adheared to for all events.

Response: Requirement R2 applies to both the Planning Coordinator and Transmission Planner because the Planning Coordinator may have a larger area than the Transmission Planner. Functional Model Version 3 states that, “Like the Resource Planners and Transmission Planners at the ‘local’ level, the Planning Coordinator maintains system models and performs the necessary studies to evaluate whether the composite resource and transmission plans of its Resource Planners and Transmission Planners are in compliance with reliability standards”. No change made.

Please suggest modifications to more accurately describe “stability” Analyses. No change made.

In the new version, Part.2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

For Part 2.1.1, Year One and year two are within the Planning Horizon. In the Definition Section, Year One is defined as “The first year that a Transmission Planner is responsible for assessing. This is further defined as the planning window that begins 12-18 months from the current calendar year”. Operating Studies are performed for system conditions within 12 months of the current calendar year. Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the Near-Term Transmission Planning Horizon: (1) A Year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled; (2) A Year one or year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. The standard provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment and to assess other years in addition to those identified in Part 2.1.1. Part 2.1.2 requires that the Planning Coordinator and/or Transmission Planner also consider off-peak conditions in addition to peak conditions because the System must be able to meet performance requirements over all demand levels. System peak condition may not represent all stressed conditions. For example, during off-peak, the Load is low, and the generation would have to be

Organization	Question 2 Comment

turned off to achieve Load-resource balance. Turning down resources within a Load area could result in reliability problems. Lowering the Load in areas with many non-dispatchable resources could also pose potential problems. As the System incorporates more and more renewable resources, some of them are non-dispatchable; a standard must be forward looking so the Planning Coordinator and Transmission Planner can identify potential problems. If studies for one of the Load periods are not needed annually, the Planning Coordinator or Transmission Planner can rely on past studies for the Planning Assessment.

The bullets under Requirement R1, Part 1.1.3 have been removed from the revised standard, so no effort was made to line up the bullets in Requirement R1, Part 1.1.3 with the first two bullets under Requirement R2, Part 2.1.3. Parts 2.1.3 (now Part 2.1.4) and 2.4.3 and associated bullet lists have been revised to provide greater clarity for the expected changes. “Installation” has been removed from the third bullet. The SDT believes it is appropriate to treat generation change and transmission changes separately and did not move retirements up to the third bullet. The extent of the variations for each item listed is left to the discretion of the Planning Coordinator or Transmission Planner who are more familiar with the system being studied. Load modeling assumptions can be varied by varying, for example, the percentage of motor Load or the customer mix. It is up to the Planning Coordinator or the Transmission Planner to decide how the assumptions would be varied.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Load level, Load forecast, or dynamic model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

Part 2.1.4 (now Part 2.1.5) is based on FERC Order 693, Paragraphs 1724 – 1727. Part 2.1.4 requires that the Planning Coordinator and/or Transmission Planner consider the possibility that a piece of major Equipment can be out of service for an extended period of time because no spare piece of Equipment is on hand or

Organization	Question 2 Comment

can be purchased and be placed in service such that the outage won't last into the next planning cycle. Loss of a transformer is given as an example as a piece of major Equipment, which if forced out of service and had to be replaced with a new transformer, may have a lead time of more than one year. However, if a company has a strategy, for example, to have spare transformers in its System, or have agreement with another entity to share spare transformers, it would significantly reduce the probability of an outage of a transformer for longer than one year. The Planning Coordinator and/or Transmission Planner will need to decide which pieces of major Equipment in their respective systems would be more vulnerable to long term outage.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2.1 has been revised to reflect your suggestion.

2.2.1 A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

Part 2.4.1 is intended to allow the use of aggregated system Load models if more accurate Load models are not available. Therefore, the second and third sentences are not in conflict.

The SDT declines to include Part 2.4.2 in Part 2.4.3 because it is not intended to be a sensitivity study because the System needs to meet performance requirements under all System conditions including peak and off-peak. In addition, the Planning Coordinator or Transmission Planner can rely on past studies as provided in Part 2.5 (Part 2.6 in the new version). For this reason Part 2.4.2 has been retained.

Part 2.5 has been revised and included as Part 2.6 as shown. The language referencing "material generation changes" has been removed from the revised standard.

2.6.1 For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Part 2.6 has been revised and included as Part 2.7 to address your concerns about mixing singular and plural possibilities. .

2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The standard does not preclude protection of the Critical Energy Infrastructure Information (CEII). The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2

Organization	Question 2 Comment
events in Table 1.	
Brazos Electric Cooperative	In R2.1, end of paragraph i believe you mean Requirement 2.5, not 2.6. In R2.6.2 we believe maintaining a 'project initiation date' serves no purpose and should be deleted. These dates are wildly variable given the nature of each project and the numerous issues that can affect these dates. 2.6.2 and 2.6.3 should be combined to simply require an in-service year/date and allow the owners to work as needed to meet these dates. We think R2.9 should be deleted as it is vague in nature, seems to serve no purpose and would be hard to verify the accuracy of the value in an audit. 2.8 is direct and can be easily detailed for an audit.
Response: In the new version, Part.2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made. Project initiation date and in service date have been removed from the requirements. Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees with the majority of commenters that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
American Electric Power	AEP agrees with R2.3., but should note that the planning horizon short circuit models are not presently developed in any systematic fashion, since, unlike the development of steady-state (power flow) and stability models that are mandated under MOD-010 and MOD-012, respectively, there are no NERC Standards that mandate the development of short circuit models in a similar fashion. As to R2.4., requiring study of both peak and off-peak conditions in every stability assessment removes the possibility in this regard that stability study scopes may be defined most appropriately by engineering judgment. We believe system load level is often important, but not necessarily more important than any of the other sensitivity variables listed under R2.4.3. We suggest listing system load level along with these and removing R2.4.1. and R2.4.2. The text in R2.4.1., referring to dynamic load modeling, may still be retained somewhere, and since this falls in the category of modeling and data, we suggest including this under R1.1. With regard to R2.5., a 20 MW increase in generation may well be construed as a material generation change, but it is questionable whether a 20 MW decrease would be for transmission planning purposes. Also, the validity of many studies, particularly plant oriented stability studies, may well extend beyond five years if there have been no transmission modifications in the vicinity of the plant or to the plant itself. In these instances, it would seem counter-productive to disqualify a study after five years. The duration of the validity of certain types of past studies is better determined by the occurrence of significant transmission or generation changes. Please note, under R2.6.2., to define project initiation date [Changed sequence to keep in numerical order].

Organization	Question 2 Comment
Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt and is not specifically related to new planned Facilities. However, a NERC-wide data base or models similar to MOD-010 or MOD-012 may be neither desirable nor necessary, since short circuit study concerns localized issues and can be contained within a study area. Part 2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. The SDT declines to include Load levels in sensitivity studies in Part 2.4.3 and remove Parts 2.4.1 and 2.4.2. Since Part 2.4.3 would only require studying one or more of the list of sensitivities, this change can result in no Stability study performed for either peak Load or off-peak Load condition in the Near-Term Transmission Planning Horizon. In addition, the standard does not require a new Stability study be performed annually; the Planning Coordinator or Transmission Planner can rely on past studies as provided in Part 2.5 (Part 2.6 in the new version). For this reason no change was made. Part 2.5 has been revised and included as Part 2.6 as shown. The reference to the “20 MW” threshold has been removed from the revised standard. **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Project initiation date has been removed from the requirements.	
ITC Holdings	Comments: In R2.1, there is a reference to R2. 6. Based on the posted red-line version, we believe this reference should be changed to R2.5. Should this same reference be included in R2.4?? In R2.3, it is stated that the short circuit analysis should be supported by either current or past studies. Should a reference be added to R2.5? In R2.6 it is stated: Corrective Action Plans do not need to be developed solely to meet the performance requirements for sensitivities run in accordance with Requirements R2.1.3 and R2.4.3. While we recognize that this conforms to FERC orders, it would still seem that this statement might be interpreted to mean that CAPs intended to cover a number of sensitivities go beyond standards and be used by interveners to block such CAPs. A revision to the standard to the standard to encourage CAP when needed for numerous sensitivities might be appropriate. R 2.6.4, as written, is very subjective. While we understand the need for R2.6.4, who is the ultimate judge of what situations are beyond the control of the TP or PC responsible for the mitigation plan and if they “are taking prudent actions to resolve the situation” As written, it is the auditor. This will be difficult to prove compliance and might provide significant discrepancies in compliance with standards.

Organization	Question 2 Comment
Response: In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made. The reference has been added. **2.4** The Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as indicated in Requirement R2, part 2.6. The following studies are required: Parts 2.3 and 2.4 have been revised to add reference to Part 2.5 (included in the new version as Part 2.6). **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. Part 2.6 has been revised and included as Part 2.7. A new Part 2.7.2 has been added to require that the Corrective Action Plan include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: **2.7.2** Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary. Part 2.6.4 has been revised and included as Part 2.7.5 to address your concerns. The word “prudent” is no longer used. **2.7.5** If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.	
Northern Indiana Public Service Company	R2.3: Clarify the requirement. Does the short circuit study examine topology for a single year, the topology in years studied using the steady state models or each year of the near term planning horizon?
Response: Part 2.3 requires that the Assessment of short circuit duty requirements are conducted annually addressing the Near-Term Transmission Planning Horizon. However, the specific methodology or assumptions to be used are left to the discretion of the Planning Coordinator or Transmission Planner.	
Minnesota Power	A) Under R2, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R2 only says Long-term Planning. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: Near-Term and Long-Term Transmission

Organization	Question 2 Comment
	Plannin?. B) Under R2.1 there is a reference to qualified past studies in R2.6. We believe that this reference should be pointing to R2.5 not R2.6. C) R2.1.4 addresses the spare equipment strategy. What is the scope of this sensitivity? Is the intent only to do a steady state analysis on equipment with long lead time spares D) Under R2.2 a System peak load study is required annually for one of the years in the assessment period. R2.2.1 requires the assessing entity to extend their planning assessment to accommodate any known longer lead time projects that may take longer than ten years to complete. It does not make sense to study the ten year horizon, then find a problem in year ten which has a solution that requires twelve years to build. For compliance with this standard, you would need to find another solution that can be built within ten years as opposed to the suggested language in R2.2.1 of extending the planning assessment beyond ten years to accommodate the solution that falls outside of the Long-Term Planning Horizon. No project solution greater than 10 years should be acceptable because it falls outside the Long-Term Transmission Planning Horizon. Suggestion to strike sub-requirement R2.2.1 from this standard. E) Requirements R2.1, R2.3, and R2.4 are written inconsistently. 2.1 says The Near-Term Transmission Planning portion of the Steady State analysis 2.3 says The short circuit portion of the Planning Assessment addressing the Near-Term Planning Horizon 2.4 says The Near-Term Transmission Planning portion of the Stability Analysis These three sentences confuse the order. As we understand, the Planning assessment has two parts: a Near-Term portion and a Long-Term portion. Each of those parts has three components: a Steady State component, a Short Circuit component, and a Stability component. We suggest the language in the standard should be structured consistently and appropriately as such) Under R2.4.3 there is ambiguity in the third bullet language new or modified Facilities and we believe that this language should mimic that of R1.1.2 in order to improve this requirement. The third bullet should read: Timing of the installation of new Facilities or changes to existing Facilities. G) The sub requirement R2.5.2 states that for steady state, short circuit, or stability analysis; the present System model shall not include any material changes, such as..etc. The present language in this section is vague and requires discretion on the part of both the Transmission Planner and the Planning Coordinator performing the assessment. For example, new transmission enhancements may have been added since the previous System model was developed. In general, such topology enhancements will only improve reliability and would not necessitate re-assessment with a newly updated System model. In addition, any significant generator additions would have been evaluated with a full separate generator interconnection study at which the full reliability of the System would have been taken into consideration. For this reason, we believe the following language for R2.5.2 would improve this requirement: For steady state, short circuit, or Stability analysis: the current System model of the assessed plan year shall not include any changes material to the assessment, as judged by the entity performing the assessment, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study year. Material generation changes could include: H) Modify R2.6.2 to remove the obligation to include the project initiation date. The inclusion of this date would add unnecessary work that is not needed to assure adequate BES reliability In addition, it is not clear whether initiation refers to

Organization	Question 2 Comment
	the commencement of engineering, design, construction, etc.

Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations

In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made.

In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Transmission equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. It is not intended to limit to steady state analyses only. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead time longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standard in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line.

> **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

As written the Planning Assessment consists of 2 parts: Near-Term Transmission Planning Horizon and Long-Term Transmission Planning Horizon, Steady State and Stability Assessments are required for both near-term and long-Term, but short circuit assessment is required only for the near-term. Part 2.3 has been revised

Organization	Question 2 Comment
to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. The 3rd bullet of Part 2.4.3 has been revised. **2.4.3 bullet 3** Expected in service dates of new or modified Facilities Part 2.5.2 has been revised and included as Part 2.6.2 to provide greater clarity. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Project initiation date has been removed from the requirements.	
LADWP	R2.3 There is no value to conduct short circuit analysis on an annual basis. Short circuit contribution is location constrained. Maximum short circuit interrupting duty cannot be determined by any planning cases; so putting this requirement in TPL will cause only confusion and will creat misleading information. If there is a need to develop a standard on how to evaluate maximum short circuit interrupting duty, the more appropriate place would be FAC. R2.1.3 Controllable Loads and DWM: DSM should not be a stand alone item in planning studies because DSM already is imbedded in load forecasts. Not sure what controllable loads are. R2.1.4 Any requirment dealing with spare parts should be handled in TOP, not TPL. TOP is the forum to develop operating procedures,"work-arounds", and so on when the non-availability of spare forced a company to develop temporary mitigations and it would be a mistake to suggest that planners should be able to consider such temporary fixes as acceptable planning solutions.R 2.5.2 The 20 MW threshold, at best, is "noise" for us. We would not be concerned with generation chnages that is 10 times this threshold. What is the rationale for requiring a new study just because there is a change in generation capability? R2.8 and 2.9 What measurements would this required information be measured against? I can't find any and if there is no measurement, it really does not belong. R2.6.2 Project initiation date is hard to define. Is it the date the project is budgeted? or the date the management approved the budget and at what level? or is it the date when engineering design is initiated? For both short term and long term planning horizons, the project in service date should be sufficient. there are too many variables to define "project initiation date" not to mention there is no measurable to benchmark such a requirement.
Response: Parts 2.3 and 2.7 are intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers supporting the BES have the interrupting capability for Faults that they will be expected to interrupt. No change made. Part 2.1.3 (now Part 2.1.4) is intended to cover sensitivity studies, for example, if DSM is imbedded in the Load forecast, the sensitivity study can simulate	

Organization	Question 2 Comment
conditions where not all effects of DSM is realizable, and the Load may be higher than studied . Controllable Load can be part of the local rate incentive program, where the customer Load can be controlled by the Transmission Operator. The bullets are examples, so the Planning Coordinator or Transmission Planner can choose the sensitivity and does not have to study, for example, controllable Load, if the related Load-Serving Entity does not have such a program. Part 2.1.4 (now Part 2.1.5) is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Transmission Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Parts .2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1. Part 2.5.2 (now 2.6.2) has been revised for clarity and the 20 MW threshold has been removed. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Project initiation date has been removed from the requirements.	
Platte River Power Authority	R2.6.2. Expand on the meaning of the "initiation date." R2.8. I don't understand the relevance of this requirement. May your intention be explained differently? R2.9. I don't understand the relevance of this requirement. May your intention be explained differently?
Response: Project initiation date has been removed from the requirements. Parts 2.8 and R2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
MAPPCOR	R2.1.1 Consider calling this Near Term years instead of specifically naming certain years.

Organization	Question 2 Comment
	R2.1.3 eliminate the last bullet. Planned duration or timing of Transmission outages is part of R1.1.1 which already specifies that models will include planned outages of generation and transmission facilities. R2.1.4 the second line is unclear. There is a reference to lead time of one year or more Is the intent for that to mean outage duration of one year or more??? If so, it should be written that way. Also, in the 3rd line, eliminate the words an analysis of (otherwise it would direct one to assess an analysis.) This in essence is an N-3 study. This risk that a TO or GO takes will show up in the operations of the BES. Also some states assess a penalty for equipment that is sitting idle that cost the taxpayers, so you could be penalize for not have spare equipment or if you do have it. R2.2.1 does this mean, for example, that entities may be doing 12 year or 15 year assessments? It should be written to say what it means. R2.4.1 Change to read: For peak System Load levels, a Load model shall be used which appropriately represents the dynamic behavior of Loads, including consideration of the behavior of induction motor Loads or an aggregate System Load model which represents the overall dynamic behavior of the Load. R2.5.1 Suggest deleting this requirement, and incorporating it into R2.5.2. R2.5.2 Incorporate R.2.5.1 into R2.5.2; please modify the section as follows:For steady state, short circuit, or Stability analysis the study shall be less than five calendar years old or less: the latest Transmission Planning Horizon System model shall not include any material changes, such as, generation or Transmission additions/removals, or topology changes that have occurred in the intervening period and would impact the study area. Material generation changes could include: The addition/deletion/change of individual generating unit capability determined to be material by the Planning Coordinator or Transmission Planner. An aggregated addition/deletion/change to a group of generating units directly connected through their step-up transformer(s) to the BES determined to be material by the Planning Coordinator or Transmission Planner. R2.6 ? The creation of hard and fast Corrective Action Plans for the LTRA is not a good use of resources. The reason for planning studies is to uncover possible weak spots in the system for some number of years into the future, and then pursue additional studies to examine the issues. Planning studies include many assumptions, and the issues may not even arise on the real system. If they do, there may be many possible remedies. Creating CAPs with milestones and other firm dates for potential problems uncovered in assessments of future years is simply not practical, and the PC (PA) may have little or no influence on what remedy is selected even if a problem appears to be real. R2.6.2 The phrase Project Initiation Date needs to be defined. It is unclear if this is this the date of ground breaking, purchase orders being issued, solution study initiation, etc. Additionally, in the second sentence the phrase as well as an in-service date should be modified to read as well as a target in-service date. R2.6.3 Plans can provide a target in-service year but not an actual in-service year. R2.6.4 recommend clarifying how situations beyond the control of the TP or PC are determined. It is unclear if this is to imply that if something is outside of the control of the department who conducts the planning studies or if it is outside the control of the registered function's legal entity (i.e. corporation). There should be a cutoff point when changes occur beyond a certain date. When that date occurs, further changes will be evaluated in the next year's assessment. Otherwise, if a state makes a decision not to site a project a few weeks prior to the end of the assessment period, there will not be sufficient

Organization	Question 2 Comment
	time to incorporate this into that year's assessment and develop corrective actions. R2.8 appears to be nonessential information for reliability; for what purpose does this requirement exist? R2.9 - appears to be nonessential information for reliability; for what purpose does this requirement exist?

Response: Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the Near-Term Transmission Planning Horizon: (1) A year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled; (2) A Year One or year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. The standard provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment, and to assess other years in addition to those identified in R2.1.1.

The last Bullet in Part 2.1.3 is intended to cover planned outages of Facilities in sensitivity studies if such planned outages are known at the time the planning studies are performed, for example, a planned outage of a major Transmission line during construction if the Corrective Action Plan calls for rebuilding of the line to a higher operating voltage. The corresponding sensitivity could simulate unplanned delay starts or unplanned extension of construction period of the planned project. No change made.

Part 2.1.4 (now Part 2.1.5) is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Transmission equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed**.** Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

> **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead time longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standard in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line.

> **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

Part 2.4.1 has been modified.

> **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

Part 2.5.1 (now Part 2.6.1) is considered a separate requirement by the SDT and has not been deleted or merged. It has been revised for clarity.

> **2.6.1** For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided

Organization	Question 2 Comment
to demonstrate that the results of an older study are still valid. Part 2.5.2 (now Part 2.6.2) has been revised for clarity. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Part 2.6 has been revised and included as Part 2.7 to address your concerns. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: Project initiation date has been deleted from the requirements. The requirement for in service date has been deleted. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees with the majority of the commenters that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in he new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Orlando Utilities Commission	-I think R2.1 has a typo and should reference requirement R2.5, not R2.6. – R2 Does the phrase “System Peak Load” require true system peak be tested, or a peak condition. As an example, FRCC experience a two peak loads, a summer peak that occurs regularl
Response: In the new version, Part 2.6 now contains the requirement for the use of past studies, so Part 2.1 now has the correct reference. No change made. System peak Load means the highest Load within the time period that is being evaluated.	
American Transmission Company	We propose the following comments for R2:In sections R2.1.3 and R2.4.3 please explain the reference to expected transfers and how that differs from R1.1.5 interchange. If these are analogous, then change the references to interchange. Modify R2.5.2 second bullet to clarify that this addresses an aggregated addition/deletion/change to a group of generating units directly connected through a shared step-up transformer . . . . Modify R2.6.2 to remove the obligation to include the project initiation date. The inclusion of this date would add unnecessary work that is not needed to assure adequate BES reliability. In addition, it is not clear whether initiation refers to the commencement of engineering, design, construction, etc.ATC agrees that the Transmission Planner should be responsible for a corrective action plan (R 2.6) and its associated sub-requirements, but we do not agree that the Planning

Organization	Question 2 Comment
	Coordinator should also be listed. Unlike a Transmission Planner, a Planning Coordinator does not have the ability or responsibility to implement a corrective action plan. Requirement 2.6 and its associated sub-requirements should be limited to only the Transmission Planner. Remove the R2.8 requirement. The activity of identifying and including the largest Consequential Load Loss caused by any P1 or any P2 events in the Planning Assessment may not assure adequate BES reliability. A P1 or P2 event with the largest Consequential Load Loss could occur at a location on the system that is strong enough to not result in any performance violation. The amount of Consequential Load Loss may not have a relevant correlation to system performance and reliability. Remove the R2.9 requirement. The activity of identifying and including the maximum permissible Non-Consequential Load Loss caused by selected Table 1 Planning Events may not assure adequate BES reliability. The maximum permissible Non-Consequential Load Loss could occur at a location on the system that is strong enough to not result in any performance violation. The maximum amount of Non-Consequential Load Loss may not have a relevant correlation to system performance and reliability. Add R2.10. The obligation to identify and observe applicable steady state voltage and post-Contingency voltage deviations should be a Requirement, rather than performance note a in the Planning Events, Steady State Only section of Table 1. And the obligation to identify and observe applicable transient voltage response limits should be a Requirement, rather than performance note b in the Planning Events, Stability Only section of Table 1. In addition, due to the system limit requirements of FAC-010 and FAC-014 the reference to the PC and TP is unnecessary. We suggest this text: The Planning Assessment shall identify the applicable steady state voltage, post-Contingency voltage deviations, and transient voltage response limits.

Response: Part 1.1.5 has been revised to state "Known commitments for Firm Transmission Service and Interchange" The NERC Glossary of Terms defines Firm Transmission Service as "the highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption" and Interchange as "Energy transfers that cross Balancing Authority boundaries. "Transfer" can cover more than Firm Transmission Service or Interchange. Parts 2.1.3 and 2.4.3 would cover the sensitivity of changes in expected transfers regardless of the cause.

Part 2.5.2 – The examples in the bullets have been deleted.

Part 2.6.2 - Project initiation date has been deleted from the requirements.

Part 2.6 has been revised and included as Part 2.7 in the new version to address your concerns. The SDT declines to limit the application of Part 2.6 to the Transmission Planner because the Planning Coordinator would be responsible for coordination between Transmission Providers.

> **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees with the majority of the commenters that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new

Organization	Question 2 Comment
version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1. The obligation to identify potential steady state, transient, post-transient and post-Contingency problems is already included in Parts 2.1 through 2.4 and in Part 2.6 (Part 2.7 in the new version). Therefore adding a new Part 2.10 is not needed.	
Turlock Irrigation District	TID expresses concern that the planning extension of R2.2.1 could lead to a scenario where a single members long term project (beyond 10 years) could then require all neighboring members to extend their own planning horizons (similar to a lowest common denominator issue) and face unnecessary technical issues.
Response: Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead time longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standard in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line. If a neighboring Planning Coordinator or Transmission Planner extends their planning horizon beyond ten years, it may be prudent for the Planning Coordinator or Transmission Planner to similarly extend the associated planning horizon, but it is not necessary for compliance of this standard. Therefore, the Planning Coordinator or Transmission Planner can choose whether to extend the planning horizon beyond 10 years for its own planning area(s) for the purpose of compliance. **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.	
New York Independent System Operator	R2.1.2 - System off-peak is more likely a stability issue than a steady state issue. If system off-peak becomes a steady state issue, it can be mitigated through generation redispatch. Accordingly, it appears that this requirement is not necessary for steady state analysis R2.1.4 - With respect to spare equipment strategy, this requirement potentially imposes a requirement to plan for three events, which is overly severe. As previously stated in R1, the system model should be a model of the projected system, which would include a long term actual forced outage. If this requirement is not referring to actual outages, then it is suggesting an N-1-1-1 analysis, which is a requirement that would require significant additional work with little value added for reliability because such contingencies have a very low probability. Under R2.5 - Past Studies may be used to support the Planning Assessment if they meet the following requirements and the sub-requirement R2.5.2 states that for SS, SC, or stability analysis “the PRESENT (emphasis added) System model shall not include any material changes, such as, . The NYISO interprets this language to mean that past studies may be used to support planning assessments as long as there are no material changes to the LATEST PLANNING HORIZON system model. The Standards Drafting Team should clarify whether this interpretation is correct. The standard should further state whether, if there was a material change such as a 20 MW generator, the past study may be used if the impact of this small change is assessed. Finally, the regional entity should have a process to determine whether changes are material that is

Organization	Question 2 Comment
	similar to the NPCCs process for determining what level of annual transmission review should be conducted each year.

Response: Regarding comment on Part 2.1.2, NERC Standards require that Systems can operate reliably over all demand levels. If steady state problems under off-peak conditions needed to be corrected through re-dispatch and/or switching to reconfigure the System, then a Corrective Action Plan involving re-dispatch and switching will need to be developed to ensure that the plan can be implemented. Since a past study can be used to support a current Assessment in accordance with Part 2.5 (Part 2.6 in the new version), an off-peak study would not have to be performed every year.

In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the “normal” (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity’s spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.5.2 (now 2.6.2) has been revised for clarity. The bullets under 2.5.2 have been removed from the revised standard.

2.6.2 For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.

Organization	Question 2 Comment
Duke Energy	R2 Instead of document results the requirement should be to summarize results. While results will be documented, the Planning Assessment should just include a summary. R2.1 What’s the value in being able to use qualified past studies if you have to use annual current studies? Strike the words supplemented with and insert the word or. R2.5.2 Suggest deleting the phrase Material generation changes could include: and the two accompanying bullets. A change of 20 MW on a large system may not always be material. R2.8 and R2.9 should be deleted. We don’t see a reliability-related need for these requirements. In the sub-requirements of 2.1.3 and 2.4.3, the use of the word timing is unclear. Consider using in service date or schedule for. R2.4.1: It is not clear how much Load a dynamic model must have. Likely, it must still be proven that the analysis software can accommodate every load in the model having a load model that includes induction motor models. To help address this, revise Load to be Load that could impact the study area is acceptable.

Response: Requirement R2 has been revised to provide greater clarity and the word, “summarize” was added in support of your suggestion.

Organization	Question 2 Comment

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.

In Part 2.1 it is envisioned that not all parts of the studies, on which the Assessment is to be based, can rely on past studies. For example, a study on year five performed during the past year may not be representative of year five in the current year. A past study can still be used if it can be demonstrated that the requirements for use of past studies are met. No change made.

2.5.2 – Both bullets under 2.5.2 have been deleted as suggested

Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees with the majority of the commenters that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only.

2.9 The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.

Parts 2.1.3 (now Part 2.1.4) and 2.4.3 have been revised.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of planned Transmission outages.

2.4.3 For each of the studies described in Requirement R2, parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

- Load level, Load forecast, or dynamic model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Facilities.

Organization	Question 2 Comment
• Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. Part 2.4.1 has been revised to reflect your suggestion. **2.4.1** System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.	
Tucson Electric Power Company	Short circuit analyses is a local phenomenon and should not be required as part of a transmission planning assessment of the BES. In any case, the effects of failure of over-stressed breakers are already included in the Events to be assessed in Table 1. For example, P2-3 and P2-4 (Internal Breaker Fault), and P4 (Stuck Breaker while attempting to clear a fault). In R2.1, we believe the reference for past studies should be Requirement R2.5 not Requirement R2.6. Also, we suggest removing the phrase supplemented with and replacing it with the word or. This phrase indicates that previous studies cannot be a primary source for the assessment, which contradicts section 2.5.Remove the phrase not already included in the studies in R2.1.3. With this phrase included, you cannot use a previous sensitivity study to support the current assessment and Requirement R2.5 allows the use of previous studies if the conditions are met. Clarity is needed in R2.1.4. The requirement to assess the Contingencies identified in Table 1 is too burdensome. This requirement does not specify any limits on the equipment for which an analysis must be conducted. As currently drafted, this could require a separate analysis for each transformer (or any long lead-time equipment) for which a spare is not available. A separate initial case would need to be developed to assess the Contingencies identified in Table 1 for each transformer. This could result in a countless number of additional cases. We recommend a threshold be established, such as all transformers with a low side voltage above 200 kV. We also recommend changing this from a separate sub-Requirement to one of the sensitivities to be considered under 2.1.3. We also believe that the statement at the end of R2.6 that indicates corrective action plans are not required solely to meet the performance requirements for sensitivities should also apply to the spare equipment requirement.Remove the phrase “not already included in the studies” in R2.4.3. With this phrase included, you cannot use a previous sensitivity study to support the current assessment and Requirement R2.5 allows the use of previous studies if the conditions are met. The 20 MW threshold identified as “material change” for generation in R2.5 is too small. The limit should be raised or based on a percentage of the study area’sinstalled generating capacity. R2.8 should be deleted. It is not necessary for reliability. What will be done with this information on the “largest Consequential Load Loss and the associated event caused by any P1 event and any P2 event” if it is documented? R2.9 should be deleted. It is not necessary for reliability. It will be difficult to determine the maximum permissible Non-Consequential Load value. It will end up being based on cost (monetary, societal, environmental, etc.), which is dependent, among other things, on the types of load being served. It very well may be a case by case situation.
Response: Part 2.3 is intended for the Planning Coordinator and/or Transmission Planner to assess the whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt. Even though the effects of short circuit capability is localized and may be related to new	

Organization	Question 2 Comment
planned Facilities, it is important to BES reliability. Part 2.3 has been revised to provide greater clarity. **2.3** The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area. Part 2.1 requires certain current studies be conducted each year for the Near-Term steady state assessment, which can be supplemented with past studies. The SDT disagrees that the statements are contradictory. No change made. Part 2.1.4 (now Part 2.1.5) has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.6 (now Part 2.7) has been revised for clarity. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: The material change wording has been deleted from the requirement. . Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
Independent Electricity System Operator	1. We think "conduct and document" is more appropriate than "prepare". Suggest to make this change. 2. We understand the reason for introducing the spare equipment strategy in R2.1.4 is to address comments raised on planned and long-term outages. However, this is not the only cause of unavailability of major Transmission equipment for more than 12 months. Construction or line upgrade program may also require certain transmission facilities be taken out of service for a protracted period. We suggest that R2.1.4 be revised to "When an entity's spare equipment strategy or transmission project construction plan could result in the unavailability of".. 3. When would PCs and TPs be expected to perform the analysis referred to in R2.1.4 ? in anticipation of the possibility of unavailability of major transmission equipment of after such unavailability has occurred or is planned?

Organization	Question 2 Comment
	4. R2.3: The first sentence is unclear and the wording can be supported is misleading. We suggest the first sentence be revised to: The short circuit analysis portion of the Planning Assessment addressing the Near-Term Transmission Planning Horizon shall be conducted annually and be supported by current or past studies. Alternatively, language similar to R2.4 may be considered: "The Near-Term Transmission Planning Horizon portion of the short circuit analysis shall be assessed annually and be supported by current or past studies. 5. R2.4 stipulates the details of the study for Near-Term Transmission Planning horizon for the stability analysis. Unlike its steady state analysis counterpart, there is no requirement stipulated for the Long-Term Transmission Planning horizon for the stability analysis. Is this intentional, or do the same conditions apply to the Long-Term stability analysis" 6. R2.6: Suggest to change in the tables to Table 1 at the end of the second sentence. 7. We agree with the VRFs, Mitigation Horizons and Measures. We also agree with the VSLs except R2.5 is not included. However, If R2.5 is meant to be explanatory (to illustrate the conditions under which past studies may be used), then the conditions should be provided in those requirements (e.g. R2.3) that allow for the use of past studies. If, however, these conditions are meant to be requirements, then their VSLs should be developed.

Response: The SDT does not see the proposed language as an improvement. No change made.

In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment.

2.1.5 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment.

Part 2.3 has been revised to provide greater clarity**.**

2.3 The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

The SDT added Part 2.5 to address your concern.

2.5 The Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed generation additions or changes in that timeframe and be supported by current or past studies.

Organization	Question 2 Comment
Part 2.6 (now Part 2.7) has been changed as suggested. **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity run in accordance with Requirements R2, parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall: The Lower VSL has been revised accordingly. R2, Lower VSL: The responsible entity failed to comply with Requirement R2, part 2.9 or Requirement R2, part 2.6.	
Kansas City Power & Light	R2.1.3 is this indicating that only one of the variations need to be studied? (in one or more of the following conditions). Recommend having the planner work with the load to determine what sensitivity studies to perform. R2.1.4 it is unclear as to what should be done with the analysis that incorporates the company's spare equipment strategy. Is this requirement inferring that a company's spare equipment strategy need to ensure that it can still operate to within the requirements for contingencies of Table 1 without the component? R2.2.1 ? is the intent to have the study for the 10 year horizon or to include any project that is started within the next 10 years and thus the study must be extended to the forecasted completion of the project (conceivably as long as 20 years or more?) R2.5.2 - Remove the word intervening and this requirement must be more specific about what this requirement is trying to communicate and acccomplish. R2.6.4 recommend clarifying how situations beyond the control of the TP or PC are determined. It is unclear if this is to imply that if something is outside of the control of the department who conducts the planning studies or if it is outside the control of the registered function's legal entity (i.e. corporation). R2.8 appears to be nonessential information for reliability; for what purpose does this requirement exist? R2.9 - appears to be nonessential information for reliability; for what purpose does this requirement exist?
Response: Part 2.1.3 (now Part 2.1.4) is intended for the Planning Coordinator or the Transmission Planner to investigate at least one of the conditions listed. Part 2.1.3 has been revised to provide greater clarity. It is expected that there will be coordination between the Planning Coordinator, the Transmission Planner and the other impacted Functional Entities. **2.1.4** For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance. • Real and reactive forecasted Load.	

Organization	Question 2 Comment
	• Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of planned Transmission outages. In Part 2.1.4 (now Part 2.1.5) when a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the "normal" (P0) condition in Table 1 and the rest of Table 1 will apply. Part 2.1.5 is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare Equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of equipment will be replaced. If not, its impact of unavailability would need to be assessed. Part 2.1.5 has been revised to require that the assessment reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time Equipment. **2.1.5** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), an analysis of the impact of this possible unavailability on System performance shall be assessed. The Planning Assessment shall reflect the P0, P1, and P2 categories identified in Table 1 during the conditions that the System is expected to experience due to the possible unavailability of the long lead time equipment. Part 2.2.1 has been revised because extending the Planning Horizon beyond 10 years for projects with lead time longer than 10 years is already covered in the definition of Long-Term Transmission Planning Horizon. This allowance is needed to provide planning flexibility, and is at the discretion of the Planning Coordinator or Transmission Planner. For example, if the System is found not to meet performance standard in year 10, but the project to correct the loading cannot be placed in service for 12 years, then the Corrective Action Plan needs to identify the interim solutions before the project can be brought on line. **2.2.1** A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected. Part 2.5.2 has been revised and included as Part 2.6.2 in the new version to provide greater clarity. **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Part 2.6.4 (now 2.7.5) does not prejudge the acceptability of the situation outside the control of the Planning Coordinator or Transmission Planner, which has prevented the implementation of the Corrective Action Plan, provided that the Planning Coordinator or Transmission Planner documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service. Parts 2.8 and 2.9 were intended to contribute to open and transparent Transmission planning for peer review. The SDT reviewed both requirements and agrees that as written, they were unclear. Part 2.9 has been deleted. Part 2.8 has been revised and included as Part 2.9 in the new version to require that the Planning

Organization	Question 2 Comment
Assessment provides the expected largest Consequential Load Loss identified by the analysis of P1 and P2 events in Table 1 only. **2.9** The Planning Assessment shall provide the expected largest Consequential Load Loss (megawatt Demand) identified by the analysis of P1 and P2 events in Table 1.	
ReliabilityFirst Corporation	R2- Suggest changing annual Planning Assessment to "annual Planning Assessment Report". Requires short circuit analysis, at present NERC wide common data base for conducting short circuit analysis, does not exist. Short circuit analysis is only performed when there are major system changes and their impact is local. R2.1.1 requires either Year One or year two, and year five. NERC members utilize Models developed by MMWG for the assessment study needs and they are usually lag by one year. R2.1.3 -Suggest changing last bullet to read "Transmission lines, Transformers, Generating unit and Reactive sources that are scheduled for extended outages during the study period should not be included in the Assessment Model." R2.4.1- The requirements in the two sentences seem to contradict each other. R2.4.2 – This does not mention modeling dynamic behavior of loads. R2.5.2 – "could include" is weak and may not be enforceable. Suggest removing all the text after the first paragraph. Does this require any additional studies to demonstrate that the changes do not impact previous conclusions? R2.7 – Short Circuit analysis should not be a part of Performance Requirements". These should be included in "PRC" Standards

Response: Requirement R2 has been revised.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.

Part 2.1.1 is intended to require studies for System Peak Load Conditions for 2 of the years in the near-term planning horizon: (1) A year five case to identify potential problem that can be addressed if the planned projects proceed as scheduled; (2) A Year One or year two case to identify any potential problems unanticipated in the five-year case, which if not addressed, could impact operations as time progresses. The standard provides flexibility for the Planning Coordinator or Transmission Planner to use past studies to support the current year assessment, and to assess other years in addition to those identified in Part 2.1.1. Therefore, if the models developed by MMWG lag by one year, it can qualify as a valid past study.

Planned outages of generation and Transmission Facilities are included in Part 1.1.1 (included as Part 1.1.2 in the new version). Transmission Facilities covers lines, reactive devices, and other substation equipment. Part 2.1.3 (now Part 2.1.4) is intended to cover sensitivity studies on "what if" scenarios. Part 2.1.4 has been revised to provide greater clarity.

2.1.4 For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model for the list of items shown below. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions not already included in the studies by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance.

Organization	Question 2 Comment
	• Real and reactive forecasted Load. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of planned Transmission outages. Part 2.4.1 is intended to allow the use of aggregated system Load models if more accurate Load models are not available. Therefore, the second and third sentences are not in conflict. In Part 2.4.1 the SDT specifies the dynamic Load model representation for on peak because the System voltages are generally lower during on peak. The percentage of motor Load, e.g., in air conditioners, could significantly increase reactive power requirements especially when they stall due to low System voltage and can therefore impact dynamic System performance on-peak. However, motor Load would likely not pose the same problem during off-peak as the System voltages are usually higher. So, in Part 2.4.2, it can be left to the discretion of the Planning Coordinator or Transmission Planner whether the dynamic motor Load would need to be represented per the requirement in Part 2.4.1, Part 2.5.2 has been revised and included as Part 2.6.2 in the new version to provide greater clarity**.** **2.6.2** For steady state, short circuit, or Stability analysis: the study shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area. Part 2.7 is intent to require a Corrective Action Plan if the short circuit duty requirement exceeds the current interrupting duty of the circuit breaker. No change made.

3. Requirement R3 – Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: Minor wording changes were made to Requirement R3 to clarify that this requirement pertains to the requirements of the studies needed to support the Planning Assessment. Several industry commenters wanted confirmation that Requirement R3 applied to both the Planning Coordinator and the Transmission Planner feeling that the requirement could result in duplication of effort. The SDT directed the commenters to Requirement R6 (now Requirement R7), which provides a mechanism for determining individual and joint responsibilities for performing the required studies for the Planning Assessment. Several clarifying changes were made to the wording of the parts under Requirement R3 to address industry comments.

R3 For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1.

R3.1 Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4.

R3.2 Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, part 3.5.

R3.3 Contingency analyses shall be performed and:

R3.3.2 Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

R3.3.3 Ensure relay loadability limits are respected.

R3.3.4 Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

R3.4 Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

R3.4.1 The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

R3.5 Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

R3, moderate VSL: The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.

Organization	Question 3 Comment
Northeast Power Coordinating Council	R3.3.2 Traditionally transmission planners have used their judgment about the minimum steady state voltage limitations of generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R3.3.3 " PRC-023 requires relay loadability to be reflected in facility ratings. Therefore this additional requirement is unnecessary and should be deleted. R3.5 ? We recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:- Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events- It should be clear that an evaluation does not require solution development for all Extreme Events- Change "an evaluation of possible actions" to "where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered. For Requirements R3.4 and R3.5, what defines "more severe System impacts"?
Response: R3.3.2: The SDT agrees that judgment is used today. There is a project (PRC-024) that will address this issue. The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure that they are being treated within the simulation as they will react in the real world. No change made for this comment. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. **R3.3.3** Ensure relay loadability limits are respected. R3.5: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, the SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event. The need to identify possible actions addresses an Order 693 directive. Your suggested wording would make identification of possible actions optional. No change made. R3.4 & R3.5: Requirement R3, parts 3.4 and 3.5 require the Planning Coordinator/Transmission Planner to prepare a list of planning event and extreme event Contingencies that, in the Planning Coordinator's and Transmission Planner's judgment, are expected to produce more severe System impacts, and to document the reasons for the Contingencies selected. The documented rationale provided by the Planning Coordinator/Transmission Planner will define what is considered to be the more severe System impacts.	
Transmission Planning	R3.3.1. COMMENT: This would make sense for 3-terminal lines which we are including in contingency files, but for normal 2-terminal lines, very unnecessary. Suggested language at the end would say "Simulation of individual element outages is allowed if it produces an effect more severe that the entire circuit outage". This implies that by modeling individual branch outages would represent more severe conditions than entire circuit outages due to the fact that there would be consequential load loss. R3.4. COMMENT: Table 1 as drafted is very confusing and could be interpreted incorrectly. Recommend revising the header for "Table 1 " Steady State & Stability Performance Extreme Events" Should be changed to "Table 2 - Steady State & Stability Performance Extreme Events" because the expected performance requirements associated with Planning Events could be

Organization	Question 3 Comment
	interpreted to be applicable to Extreme Events as well. Alternatively, the performance requirements at the top of Table 1 need to include a statement that they are applicable to Planning Events only.
Response: R3.3.1: The SDT disagrees with the comment as the intent of Requirement R3, part 3.3.1, consistent with FERC Order 693, is to perform the simulation to reflect how the Protection System will operate in the real System for each Contingency without operator intervention. The requirement does not preclude the Planning Coordinator/Transmission Planner from studying individual elements or other maintenance scenarios. Planning event P2-1 addresses an element outage configuration. Please also see footnote 8. No change made. R3.4: The SDT feels that the table headings are sufficiently clear as stated. No change made.	
SERC Engineering Committee Planning Standards Subcommittee	R3.1:In Requirement R3.1, it is suggested that the word "contingency" be added to describe the lists created in R3.4.: "Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created in Requirement R3.4. R3.3.1: Recommend that it be clarified that simulation of the more conservative case of a single branch (bus-to-bus) outage is acceptable, as opposed to always simulating the full breaker-to-breaker outage. R3.3.2The requirement needs to be clarified. It is not clear if it is referring to the ability of plants to meet their voltage schedule, or to their ability to stay connected during post contingencies. R3.3.4:In Requirement R3.3.4, it is suggested adding the words "and switched" to capacitors and reactors:"Simulate the expected operation of existing and planned devices designed to provide Steady State control of electrical system quantities. These devices include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.
Response: R3.1: The SDT agrees and has modified Requirement R3, part 3.1 accordingly **R3.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4. R3.3.1: The SDT disagrees with the comment as the intent of Requirement R3, part 3.3.1, consistent with FERC Order 693, is to perform the simulation to reflect how the Protection System will operate in the real System for each Contingency without operator intervention. The requirement does not preclude the Planning Coordinator/Transmission Planner from studying individual elements or other maintenance scenarios. Planning event P2-1 addresses a branch outage configuration. Please also see footnote 8 (now footnote7). No change made. R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.4: The SDT agrees and has revised the wording. **R3.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities	

Organization	Question 3 Comment
when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.	
Modesto Irrigation District	On page 10 under Section R3.3.3, I believe more specifics on what is meant by "relay loadability" need to be given in regard to the requirement of "identify how loadability is analyzed in the steady state simulation". For example, does the analyst need to state that the maximum loading allowed on any system element is less than or equal to 150% of the element's maximum seasonal rating ? We believe that R3.3.1-R3.3.4 should be bullets under R3.3
Response: R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected. R3.3.1-R3.3.4: The SDT disagrees as these are mandatory requirements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. No change made.	
OPUC	3. Requirement R3 ? Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.Comments:A: R3.3 should be modified to become the requirement to conduct contingency analyses with R3.3.1 thru 4 presented as bullets there-under.
Response: R3.3.1-R3.3.4: The SDT disagrees as these are mandatory requirements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. No change made.	
Bonneville Power Administration	R3.1 should be clarified. Suggested clarification: R3.1 - "Studies shall be performed to determine whether the BES meets the performance requirements in Table 1. A reduced set of contingencies can be simulated based on a list created in requirement R3.4." As currently drafted, R3.3 is not a requirement. Without the statements in R3.3.1-R3.3.4, R3.3 is simply a phrase. Sub-Sub-Requirements R3.3.1 through R3.3.4 should be bullets under R3.3, with the language in R3.3 modified so that it becomes the requirement to conduct contingency analyses that address the four resulting bullets R3.3.2 is unclear as drafted. The minimum steady state voltage limitation for synchronous generators is not a very meaningful value. All generators with an automatic voltage regulator will maintain the set point voltage until the VAR capability of the generator is exceeded, and then the voltage will deteriorate. Requirement R3.4 also needs to be clarified as follows: R3.4 - "A reduced list of Contingencies can be developed for System Performance evaluation in Requirement R3.1 that includes those Planning Event Contingencies that are expected to produce more severe System impacts based on system performance as required in Table 1. "The Statement at the end of R3.4 and R4.4 says "rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an

Organization	Question 3 Comment
	explanation of why the remaining Contingencies would exhibit better system performance." The statement does not make sense and should be deleted since the contingencies selected are those to produce more sever system performance. R3.5 ? We disagree with the requirement to explain why remaining Extreme Contingencies would produce less severe System results than the ones selected for study. The first part of the requirement requires identification of events that produce more severe System impacts. The reason the others were not selected is because they were less severe or non-credible. In any case, theoretically, there can always be a more severe Extreme Contingencies than the one selected for study. For example, if the Extreme Contingency studied were simultaneous loss of 3 transmission lines with failure of redundant RAS, then simultaneous loss of 4 lines with failure of 2 sets of redundant RAS would be more severe. Listing all possible extreme events could result in a limitless list.

Response: R3.1: The SDT agrees and has modified the requirement.

> **R3.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4.

R3.3:The SDT has modified the wording to provide greater clarity. The SDT disagrees that Requirement R3 parts 3.3.1- 3.3.4 should be bullets as these are mandatory parts of the required contingency analyses. Bullets are only used to identify the possible but not all inclusive elements of a menu. No change made.

> **R3.3** Contingency analyses shall be performed and:

R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world.

> **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

R3.4: The SDT has made a revision to the posted wording of the requirement to add clarity and address your comment.

> **R3.4** Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

R3.4 & R4.4: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the Contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".

R3.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".

> **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible

Organization	Question 3 Comment
actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.	
MRO MRO NERC Standards Review Subcommittee	MRO NSRS proposes the following comments for R3.Revise the R3.3.2 text to clarify that subsequent analysis is performed on generators whose voltages are expected to fall below the minimum voltage limits. MRO NSRS suggests this text: "Consider the minimum steady state voltage limitations of all generators and identify how generators with bus voltages below its minimum voltage limits are analyzed in the subsequent steady state simulations. Revise the R3.3.3 text to more clearly relate to the specific requirements in PRC-023. MRO NSRS suggests this text: "Incorporate relay loadability per PRC-023 and identify how relay loadability is analyzed in the steady state simulation.
Response: R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement. **R3.3.3** Ensure relay loadability limits are respected.	
SERC Engineering Committee Dynamics Review Subcommittee (DRS)	R3.3.3 applies to "all Transmission lines. Should this only apply to lines above 230 kV and lines identified as critical below 230 kV" At least this should be limited to BES lines. R3.3.4 says "Simulate the expected operation of existing and planned devices designed to provide Steady State control of electrical system quantities. This should say, "Simulate the expected operation of existing and planned BES devices designed to provide Steady State control of BES electrical system quantities.
Response: R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected. R3.3.4: The SDT disagrees as this standard only applies to the BES. No change made.	
SERC Engineering Committee Reliability Review Subcommittee (RRS)	In R3, should the "and" in the first sentence actually be "or"? especially for same footprint? Perhaps the "and" should be replaced by "and/or". Can the PC satisfy this requirement by reviewing studies performed by differing TPs or is separate analysis really required especially when the TP and PC have the same footprint"? In Requirement R3.1, it is suggested that the word "contingency" be added to describe the lists created in R3.4. R3.3.1. Recommend that it be clarified that simulation of the more conservative case of a single branch (bus-to-bus) outage is acceptable, as opposed to always simulating the full breaker-to-breaker outage. R3.3.2The requirement needs to be clarified. It is not clear if it is referring to the ability of plants to meet their voltage schedule, or

Organization	Question 3 Comment
	to their ability to stay connected during post contingencies. Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created in Requirement R3.4. "R3.3.2"For all generators, studies shall consider the minimum steady state voltage limitations and identify how the generators are analyzed in the steady state simulation. The above wording needs to be changed, as the intent of this sentence is unclear. Is the intent that Transmission Planners need to ensure that generating plants can meet their voltage schedule under Base Case (N-0) conditions? Is this the same as the generator underexcited operation limit?? In R3.3.2, need guidance on how to consider minimum steady state voltage limitations. Is there a NERC team addressing this" R3.3.3"For all Transmission lines, studies shall consider relay loadability and identify how loadability is analyzed in the steady state simulation. The above wording needs to be changed, as the intent of this sentence is unclear. Is the intent that Transmission Planners need to ensure that relay loading limits are included in the facility ratings? Is this the 130% of conductor rating limit?? Revise M3 to include a reference to R6, since the allocation of responsibilities will directly affect the evidence which is to be provided. In the VSL for R3, a severe VSL is listed as failing to meet performance requirement for P0 or P1. We do not understand why a severe VSL would be applied to an all ties closed event which should have little if any problems. We believe that this should be a lower or moderate VSL instead of severe. In R3.3.3 is the relay loadability required for all HV and EHV voltage levels? Previously NERC had required this for 230-kV and above only. This would be massive requirement for our Transmission Lines between 100 and 200-kV. Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created in Requirement R3.4. ? In Requirement R3.3.4, it is suggested adding the words "and switched" to capacitors and reactors: Simulate the expected operation of existing and planned devices designed to provide Steady State control of electrical system quantities. These devices include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

Response: R3: The SDT believes that the requirement belongs to both the Planning Coordinator and the Transmission Planner. Requirement R7 provides a mechanism for determining individual and joint responsibilities for performing the required studies for the Planning Assessment regardless of whether the Planning Coordinator and Transmission Planner footprints overlap or not. No change made.

R3.1. The SDT agrees and has modified the requirement.

> **R3.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4.

R3.3.1: The SDT disagrees with the comment as the intent of Requirement R3, part 3.3.1, consistent with FERC Order 693, is to perform the simulation to reflect how the Protection System will operate in the real System for each Contingency without operator intervention. The requirement does not preclude the Planning Coordinator/Transmission Planner from studying individual elements or other maintenance scenarios. Planning event P2-1 addresses a branch outage configuration. Please also see footnote 8 (now footnote 7). No change made.

R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage

Organization	Question 3 Comment
limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. There is a project (PRC-024) that will address this issue of minimum steady state voltage limitations. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected. M3: The SDT disagrees. Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis required to meet the requirements of the TPL standard and to the Corrective Action Plan developed as part of the assessment. The intent of this requirement is to clarify that TPL requirements can be met through joint or shared analysis. Coordinating and/or joint analysis does not alleviate the responsibility that all entities need to comply with the standard requirements. Therefore, the SDT sees no reason to link Requirement R3 directly to Requirement R6 (now Requirement R7) in the measure or anywhere else. The requirements stand by themselves and do not require such a linkage. No change made. VSL: The SDT disagrees with your assessment. The failure to perform studies to determine the BES meets performance requirement for the P0 and P1 categories is deemed to be severe as these categories represent steady state (no Contingency) and single Contingency (probable) operation and are significant elements of the overall requirement. No change made. R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. R3.3.4: The SDT agrees and has revised the wording. **R3.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.	
FirstEnergy Corp	Specific comments, Requirements of R3:A. R3: For readability revise "computer simulations using models utilizing data" to "computer simulation models utilizing data" B. R3.3.2: The intent of this requirement is not clear. What is the voltage limitation sought? Vmin at the generator terminals, high-side of the GSU, low-side GSU, etc. Also the requirement text "identify how the generators are analyzed in the steady state simulation" does not drive a particular reliability goal. If the objective is to require tripping of units during a contingency simulation that are identified to be below their stated Vmin then the requirement should clearly state that the unit should be tripped and solution resolved. C. R3.3.3: This requirement should be removed as it is redundant with facility rating requirements stated in PRC-023, FAC-008 and FAC-009. D. R3.3.4: For readability we suggest inserting the word "may" in between "devices include".We agree with the stated Measures, VRF, Time-Horizon, Data Retention and VSL of requirement R3
Response: R3: The SDT has revised the wording accordingly.	

Organization	Question 3 Comment
R3 For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections **R3.3.3** Ensure relay loadability limits are respected. R3.3.4: The STD has added the word "may" in between "devices include". **R3.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors. Measures, VRF, Time Horizon, Data Retention and VSLs: Thank you for your comment.	
TVA System Planning	In R3.3.2, need guidance on how to consider minimum steady state voltage limitations. Is there a NERC team addressing this? It is not clear if it is referring to the ability of plants to meet their voltage schedule, or to their ability to stay connected during post contingencies. In R3, should the "and" in the first sentence actually be "or"? especially for same footprint? Perhaps the "and" should be replaced by "and/or". Can the PC satisfy this requirement by reviewing studies performed by differing TPs or is separate analysis really required especially when the TP and PC have the same footprint? In the VSL for R3, a severe VSL is listed as failing to meet performance requirement for P0 or P1. We do not understand why a severe VSL would be applied to an all ties closed event which should have little if any problems. We believe that this should be a lower or moderate VSL instead of severe. In R3.3.3 is the relay loadability required for all HV and EHV voltage levels? Previously NERC had required this for 230-kV and above only. This would be massive requirement for our TLs between 100 and 200-kV.
Response: R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. There is a project (PRC-024) that will address this issue. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through	

Organization	Question 3 Comment
voltage limitations. Include in the assessment any assumptions made. R3: The SDT believes that the requirement belongs to both the Planning Coordinator and the Transmission Planner regardless of whether the Planning Coordinator and Transmission Planner footprints overlap or not. No change made. VSL: The SDT disagrees with your assessment. The failure to perform studies to determine the BES meets performance requirement for the P0 and P1 categories is deemed to be severe as these categories represent steady state (no Contingency) and single Contingency (probable) operation and are significant elements of the overall requirement. No change made. R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected.	
Exelon Transmission Planning	In R3.3.2 it should be clear that the TP / TO is not required to provide whatever voltage that the unit desires and that the intent of this requirement is to ensure that if a generator is going to trip due to low voltage that the simulation will include the generator tripping. 3.3.2 and 3.3.3. are somewhat redundant with 3.3.1 " suggest rewording 3.3.1 to say including transmission lines with respect to relay loadability and generators with respect to minimum operating voltage. If 3.3.3 is targeting the low voltage ride through capability of the wind generators it should be clear.
Response: R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and that they are being treated within the simulation as they will react in the real world (in your comment 3.3.3 referring to low voltage ride through, we assume in our response that you were referring to 3.3.2) **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.2 & R3.3.3: The SDT does not agree that Requirement R3 parts 3.3.1, 3.3.2 and 3.3.3 are somewhat redundant as they require distinctly different simulation actions. No change made. R3.3.3: This requirement is for all generators, not just wind. It is important for the planning models to accurately reflect how the System will actually perform.	
Southern Company	R3.3.3 applies to "all Transmission lines. To be consistent with the relay loadability standard, this should only apply to lines above 230 kV and lines between 100 kV and 230 kV identified as critical. R3.2 and R3.5 are both addressing the Extreme Events. However, R3.2 is referring to R3.5 while R3.5 is referring to R3.2. We suggest deleting the reference back to R3.2 which is in R3.5. A similar situation exists for R3.1 and R3.4. R3 seems to use the words studies and analyses interchangeably. Did the SDT intend for them to be the same? Using one term or the other would be better understood.

Organization	Question 3 Comment
	There are two tables labeled table 1. It would be much clearer to mark them table 1 Planning Events and table 2 Extreme Events.
Response: R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected. R3.1 & R3.4 and R3.2 & R3.5: The SDT has decided to retain the back references for clarity. No change made. R3: The SDT agrees that use of studies and analyses can be confusing. The wording in Requirement R3 has been revised to use studies. **R3** For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. Table 1: Based on Industry feedback, the SDT has decided to have one Table and believes that the headings are sufficiently clear to distinguish between planning and extreme events. No change made.	
United Illuminating	R3.3.2 Comment Traditionally transmission planners have used their judgment about the minimum steady state voltage limitations of generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R3.3.3 Comment ? PRC-023 requires relay loadability to be reflected in facility ratings. Therefore this additional requirement is unnecessary and should be deleted. R3.5 Priority Comment ?We recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:- Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events- It should be clear that an evaluation does not require solution development for all Extreme Events- Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered.
Response: R3.3.2: The SDT agrees that judgment is used today. There is a project (PRC-024) that will address this issue. The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. **R3.3.3** Ensure relay loadability limits are respected. R3.5: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the	

Organization	Question 3 Comment
possibility or limit the consequences of an extreme event. The need to identify possible actions addresses an Order 693 directive. Your suggested wording would make identification of possible actions optional. No change made.	
System Protection and Transmission Planning Department	R3 appears to require redundant studies by TP and PC.If the TP and PC participate in the same studies, would this meet the intent of this requirement? This would include studies that are RRO sponsored, or performed by sub-regional planning groups.
Response: R3: The SDT believes that the requirement belongs to both the Planning Coordinator and the Transmission Planner. Requirement R7 (formerly Requirement R6) provides a mechanism for determining individual and joint responsibilities for performing the required studies for the Planning Assessment regardless of whether the PC and TP footprints overlap or not. No change made.	
PPL Energy Plus	It appears there is a 24 month grace period to allow modeling updates to meet R 3.3.1. This is a good idea since the powerflow computer models may not include the required data and will need to be updated.
Response: Thank you for your comment.	
PacifiCorp Deseret Generation & Transmission SRP Arizona Public Service Co Southern California Edison Company Western Area Power Administration Pacific Gas and Electric Co, Puget Sound Energy, Inc. NV Energy San Diego Gas and Electric Co California ISO Tucson Electric Power Company	As currently drafted, R3.3 is not a requirement. Without the statements in R3.3.1-R3.3.4, R3.3 is simply a phrase. Sub-Sub-Requirements R3.3.1 through R3.3.4 should be bullets under R3.3, with the language in R3.3 modified so that it becomes the requirement to conduct contingency analyses that address the four resulting bullets R3.3.2 is unclear as drafted. The minimum steady state voltage limitation for synchronous generators is not a very meaningful value. All generators with an automotive voltage regulator will maintain the set point voltage until the VAR capability of the generator is exceeded, and then the voltage will deteriorate. R3.5 ? We disagree with the requirement to explain why remaining Extreme Contingencies would produce less severe System results than the ones selected for study. The first part of the requirement requires identification of events that produce more severe System impacts. The reason the others were not selected is because they were less severe or non-credible. In any case, theoretically, there can always be a more severe Extreme Contingencies than the one selected for study. For example, if the Extreme Contingency studied were simultaneous loss of 3 transmission lines with failure of redundant RAS, then simultaneous loss of 4 lines with failure of 2 sets of redundant RAS would be more severe. Listing all possible extreme events could result in a limitless list.
NorthWestern Corporation NorthWestern Energy (NWE)	R3.3 is unclear. Requirements R3.3.1 through R3.3.4 should be bullets under R3.3, with R3.3 modified so that it becomes the

Organization	Question 3 Comment
(NWMT)	requirement to conduct contingency analyses that address the four resulting bullets R3.3.2 is unclear. The minimum steady state voltage limitation for synchronous generators is not a very meaningful value. All generators with an automatic voltage regulator will maintain the set point voltage until the VAR capability of the generator is exceeded, and then the voltage will deteriorate. In R3.3.3 the term "loadability" needs to be defined. R3.5 needs to be modified. It would be better to combine R3.2 with R3.5. The first part of the requirement requires identification of events that produce more severe System impacts. The presumed reason that the other contingencies were not selected is because they were deemed to be less severe or non-credible. In any case, theoretically, there can always be examples of more severe Extreme Contingencies than the one selected for study. This can be achieved by simply choosing events that are even less credible. For example, if the Extreme Contingency studied was a simultaneous loss of 3 transmission lines with the failure of a redundant RAS (SPS), then an event resulting in the simultaneous loss of 4 lines with the failure of 2 sets of redundant RASs would be even more severe. Listing all possible extreme events could result in a limitless list.
Response: R3.3: The SDT has modified the wording to provide greater clarity. The SDT disagrees that Requirement R3, parts 3.3.1- 3.3.4 should be bullets as these are mandatory requirements of the contingency analyses. Bullets are only used to identify the possible but not all inclusive elements of a menu. **R3.3** Contingency analyses shall be performed and: R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the Contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results". **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.	
Western Area Power Administration	R3.3.3 should be covered in the PRC Standards. While R3.3 is labeled as "Contingency analysis", R3.3.4 is related to Steady State control and therefore should not be within R3.3.
Response: R3.3.3**:** The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. **R3.3.3** Ensure relay loadability limits are respected. R3.3.4: The SDT disagrees with your comment. The simulation of the expected operation of devices such as phase-shifting transformers, load tap changing transformers, etc., impacts the post-Contingency performance of the System. No change made.	

Organization	Question 3 Comment
Tampa Electric	Consider revising standard for clarity. Subrequirements are not clear as written. Consider moving subrequirements R3.3.1 - R3.3.4 under other requirements for clarification. R3.5 Including an explanation of why remaining contingencies would produce less severe system results could be a limitless effort. Listing all "possible" extreme events seems unrealistic.
Response: The SDT requires more information in order to respond to your request to clarify the standard and sub-requirements. Numerous clarifications have been made to the fourth posting due to specific industry comments. R3.3.1-R3.3.4: The SDT disagrees as these are mandatory requirements of the Contingency analyses. No change made. R3.5: Several industry commenters have indicated that an explanation of “why the remaining Contingencies would produce less severe System performance” should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an “explanation of why the remaining contingencies would produce less severe System results”. **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.	
Florida Reliability Coordinating Council, Inc - Transmission Working Group	R3.3.1 & 3.3.4 “ Consider adding language that the entity should not be held responsible for simulating “the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention? on neighboring systems, only on the entity’s own system. Also, consider moving R3.3.1 and R3.3.4 under R3.1 as sub-requirements and require that the overall studies take into account the effect of protection systems and control devices in the performance of the BES and it’s ability to meet the table 1 requirements. R3.3.1 ? This seems unnecessary for normal 2-terminal lines, consider adding language to the effect of: “Simulation of individual element outages is allowed if it produces an effect more severe than the entire circuit outage”. R3.4 - Consider changing the header for table 1 - “Steady State & Stability Performance Extreme Events” to Table 2 - “Steady State & Stability Performance Events”. As is, it could be interpreted that the expected performance requirements associated with Planning Events apply to Extreme Events also.
Response: R3.3.1 & R3.3.4: The SDT has determined that it is necessary for the Planning Coordinator and Transmission Planner to coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list created in Requirement R3, part 3.4. Consequently, “the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention” will also apply for the Contingencies on adjacent Systems. The fourth draft of the standard will include this change by adding Requirement R3, part 3.4.1. **R3.4.1** The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.	

Organization	Question 3 Comment
The SDT believes that Requirement R3, parts 3.3.1 and 3.3.4 are separate mandatory requirements and disagrees that they should be moved under Requirement R3, part 3.1. No change made. R3.3.1: The SDT disagrees with the comment as the intent of Requirement R3, part 3.3.1, consistent with FERC Order 693, is to perform the simulation to reflect how the Protection System will operate in the real System for each Contingency without operator intervention. The requirement does not preclude the Planning Coordinator/Transmission Planner from studying individual elements or other maintenance scenarios. Planning event P2-1 addresses an individual outage configuration. Please also see footnote 8. No change made. R3.4 Table 1: Based on Industry feedback, the SDT has decided to have one Table and believes that headings are sufficiently clear. No change made.	
FMPA	R3.1, The criteria in Table 1 do not allow load shedding following a single contingency (e.g., the old footnote "b" was removed). While we agree this ought to be the case for the EHV system, we believe that there are cases where for the HV system, which often acts more like a distribution system, the costs to meet this standard would be prohibitive and unfair to the consumers served by those utilities. For instance, the Florida Keys served by the Florida Keys Electric Coop (FKEC) and Keys Energy Services (KEYS) is connected to the mainland by two 138 kV lines down to Tavernier Key (about 1/3rd the distance from the mainland to Key West). Currently, the system is planned and operated under single contingency to allow non consequential load shedding automatically via Under-Voltage Load Shedding, and to meet thermal limits by manual load shedding, all load shed is in the Florida Keys following the single contingency with no impact to the Bulk Electric System. The standard, as written, would force one of two things: 1) the construction of a third line in this environmentally pristine area at a very high cost that might increase rates to customers in the Florida Keys by 20% for a level of reliability that much of the Keys would not even experience since 2/3rds of the Keys is fed by a radial line with consequential load loss; or 2) separate the two lines such that both are operated radially with resultant consequential load loss, compliant with the standards, but actually causing consumers to have a lower level of reliability. We propose to reinstate footnote "b" for the HV system, allowing non-consequential load loss for lower voltage system that have little to no impact on the Bulk Electric System and limit the elimination of non-consequential load loss to be applicable to only the EHV. Alternatively, but less appealing and more of an administrative challenge would be to establish a Regional Entity administered process for application for exception to this criteria. FERC's Order 693 at paragraph 1794 states that: "(t)he Commission also clarifies that an entity may seek a regional difference to the Reliability Standard from the ERO for case-specific circumstances". We interpret this as meaning the Regional Entity can allow exceptions under certain criteria such as a significant increase in costs to consumers with little discernable benefit as is the case with the Florida Keys. For R3.2, we are at a loss of how a hurricane event can be modeled, and why such an evaluation is needed. Albeit, many contingencies can occur during a hurricane event, it is not likely that multiple contingencies will happen within the same < 1 minute window it takes to go from transient stability conditions to steady state conditions, and then it is unlikely that multiple significant contingency events will occur within the 30 minutes it takes operators to adjust the system to prepare for the next contingency. Therefore, we do not understand the significance of modeling a hurricane event. In addition, a hurricane can have an infinite number of different scenarios and time-lines of contingencies and picking one or two would be a meaningless exercise since an actual hurricane will be completely different than what is modeled. At least an earthquake has a fault line that makes it relatively easier to identify which facilities might be affected, but a hurricane has an infinite number of possibilities. We suggest eliminating hurricanes from extreme events and model potential results of a hurricane, such as loss of a ROW, loss of a substation or plant, and loss of a major load center. R3.3, the list ought to consider contingencies on neighboring systems that could impact the TP's / PC's system (this comment

Organization	Question 3 Comment
	would not carry over to R4.3 since stability is more a protection system / clearing time issue). R3.3.1, the entity should not be held responsible for simulating "the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention" on neighboring systems, only on the Entity's own system. R3.4 and the first part of R3.5 ought to be combined, e.g., both require justification for why a limited set of worst case contingencies are studied for N-1, N-2 and extreme contingencies. The latter part of R3.5 concerning cascading outages for an extreme contingency should become the only requirement of R3.5 (there are currently two requirements embedded within R3.5).

Response: R3.1: To comply with Order 693, the SDT have decided to raise the performance requirements such that Non-Consequential Load loss should not be allowed for P1 events of Table 1. No change made.

R3.2: Table 1 extreme events: Requirement R3, part 3.5 requires the Planning Coordinator/Transmission Planner to identify and compile a list of the extreme events that are expected to produce more severe System impacts, along with a rationale for selection of those Contingencies. The wide area extreme events such as item 3.iv are provided as examples and not meant to be a mandatory list of events to be simulated. No change made.

R3.3: The SDT assumes that the comment "R3.3, the list ought to consider contingencies on neighboring systems that could impact the TP's / PC's system" actually refers to Requirement R3, part 3.4 where the Contingency list is created. The SDT agrees with your comment and has determined that it is necessary for the Planning Coordinator and Transmission Planner to coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list created in Requirement R3, part 3.4. The fourth draft of the standard will include this change by adding Requirement R3, part 3.4.1. The need to include Contingencies on adjacent Systems will also apply to Stability.

> **R3.4.1** The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

R3.3.1: The SDT has determined that it is necessary for the Planning Coordinator and Transmission Planner to coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list created in Requirement R3, part 3.4. Consequently, "the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention" will also apply for the Contingencies on adjacent Systems. The fourth draft of the standard will include this change.

R3.4 & R3.5: The SDT does not agree that these requirements should be combined. Requirement R3, part 3.4 requires the development of a Contingency list of planning events, and Requirement R3, part 3.5 requires a Contingency list of extreme events - two separate requirements. The SDT agrees that both require that a rationale be provided for stating why the events selected are expected to produce the more severe System impacts. No change made.

R3.5: The SDT disagrees and sees no reason to split these out as they would still be essentially the same requirement. No change made.

Organization	Question 3 Comment
CPS Energy	Requirement R3.3.2. needs clarification.

Response: R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world.

> **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through

Organization	Question 3 Comment
	voltage limitations. Include in the assessment any assumptions made.
MidAmerican Energy Company	MidAmerican commends the SDT for it hard wok on this standard and specifically its R3.3.1 wording. MidAmerican has suggestions for the following parts of R3:" . " R3.3.2 " delete the words "For all generators" at the beginning. It is unnecessary in that later in the requirement it states specifically that the responsible entity is to "identify how the generators are analyzed in the steady state limitation". R3.3.3 " use a similar construction to R3.3.2 but delete the words "For all transmission lines". In other words, replace "For all Transmission lines, studies shall consider relay loadability and identify how loadability is analyzed in the steady state limitations. With "Studies shall consider relay loadability and identify how loadability for transmission lines is analyzed in the steady state simulations. " R3.4 and R3.5 " change "remaining Contingencies" to "remaining unselected Contingencies".

Response: Thank you for your comments.

R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world.

> **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis

> **R3.3.3** Ensure relay loadability limits are respected..

R3.4 & R3.5: The SDT has revised Requirement R3, parts 3.4 and 3.5 by eliminating the requirement to provide the rationale for the unselected Contingencies.

> **R3.4** Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

> **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

Organization	Question 3 Comment
Northeast Utilities	R3.3.2 Comment - Traditionally transmission planners have used their judgment about the minimum steady state voltage limitations of generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to inclusion of R3.3.2 as a requirement in this standard. R3.3.3 Comment - PRC-023 requires relay loadability to be reflected in facility ratings. Therefore this additional requirement is

<table>
<tr><th>Organization</th><th>Question 3 Comment</th></tr>
<tr><td></td><td>unnecessary and should be deleted.

R3.5 Priority Comment - We recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:-Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events-It should be clear that an evaluation does not require solution development for all Extreme Events-Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered.</td></tr>
<tr><td>ISO New England, Inc.

Central Maine Power Company</td><td>R3.3.2 Comment - Traditionally transmission planners have used their judgment about the minimum steady state voltage limitations of generators. R3.3.3 Comment - PRC-023 requires relay loadability to be reflected in facility ratings. Therefore this additional requirement is unnecessary and should be deleted.

R3.5 Priority Comment -We recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:- Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events- It should be clear that an evaluation does not require solution development for all Extreme Events- Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered.</td></tr>
<tr><td colspan="2">Response: R3.3.2: The SDT agrees that judgment is used today. There is a project (PRC-024) that will address this issue. The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world.

R3.3.2 Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections.

R3.3.3 Ensure relay loadability limits are respected.

R3.5: extreme events: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, the SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event. No change made.</td></tr>
<tr><td>JEA</td><td>R3. Change wording from "The studies shall be based on computer simulations using models utilizing data provided in Requirement R1." to "The studies shall be based on computer simulations using models that are the best representation of the future planned system and its associated use as provided by Requirement R1. The studies shall detail the effects of all future</td></tr>
</table>

Organization	Question 3 Comment
	equipment connectivity and topology arrangements and their associated Protection system responses to Contingency events regardless of model details." R3.3.2. I assume the concern here is on voltage ride through of generators and generator auxillary equipment. Propose changing language from "For all generators..." to"Include analysis of how generator and generator auxillary equipment over and under voltage protection and ride through capability were considered for the post-contingency steady state bus voltage levels." R3.3.3. I assume the concern here is ensuring consideration is given to how system protection relays could respond to post-contingency circuit emergency loadings. Protection systems that could limit the emergency ratings of transmission circuits should be considered in the Facitility Rating standard and therefore not necessary to include in the TPL standard. However, if requirement does remain in the TPL standard, propose changing language from:"For all transmission lines..." to"Include analysis of how implemented relay protection systems and their potential automatic response prior to timely corrective actions are considered for the post-contingency steady state circuit loadings".
Response: The SDT has revised Requirements R1 and R3 to provide greater clarity to the SDT's intent. **R1** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions **R3** For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. **R3.3.3** Ensure relay loadability limits are respected.	
SMUD	R3.5Listing all possible scenarios for studying extreme contingencies will result in a limitless list. Discretion should be given to the transmission planner on the selection of the contingencies without a requirement to list why other extreme contingencies have not been included. R3.3.2:When the word, 'consider' is used, it can be read as a guidance and not a requirement. The requirement is unclear.
Response: R3.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the Contingencies selected are those to produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".	

Organization	Question 3 Comment
R3.5 Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted. R3.3.2: The wording has been changed to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.	
Progress Energy Florida, Inc.	Concerning R3.3.1, PEF believes that, in virtually every conceivable scenario, contingency analyses show that analysis of individual elements will reveal overloading or undervoltages, whereas the same event modeled according to protection system design (i.e. simulating the event as the actual “breaker-to-breaker” operation would occur) may not. Analysis of individual elements is therefore a more conservative method for studying the BES. PEF is not opposed to analysis of entire circuit outages; PEF therefore suggests that in addition to the existing language of R3.3.1, an additional sentence be added as follows: “Simulation of the loss of individual elements is acceptable in lieu of simulating the loss of all elements in a protection zone if it produces greater overloads or lower voltages. This approach would allow for more efficient coordination with Transmission Operators as they schedule planned outages or make system adjustments in outage scenarios.
Response: R3.3.1: The SDT disagrees with the comment as the intent of Requirement R3, part 3.3.1, consistent with FERC Order 693, is to perform the simulation to reflect how the Protection System will operate in the real System for each Contingency without operator intervention. The requirement does not preclude the Planning Coordinator/Transmission Planner from studying individual elements or other scenarios. Planning event P2-1 addresses an individual element outage configuration. Please also see footnote 8 (now footnote 7). No change made.	
Xcel Energy	R3.3.3: Relay loadability has no bearing beyond the near term horizon. Loadability is not determined several years out. R3.5 “ does this imply that mitigation plans must be implemented” If not, then this is highly subjective and the last sentence of this requirement should be deleted.
Response: R3.3.3: The SDT does not agree with your comment**.** No change made. R3.5: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, the SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event. The need to identify possible actions addresses an Order 693 directive. No change made.	
Ameren	In Requirement R3.1, it is suggested that the word "contingency" be added to describe the lists created in R3.4. Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created

Organization	Question 3 Comment
	in Requirement R3.4. R3.3.2 -For all generators, studies shall consider the minimum steady state voltage limitations and identify how the generators are analyzed in the steady state simulation. The above wording needs to be changed, as the intent of this sentence is unclear. It is not clear whether Transmission Planners need to ensure that generating plants can meet their voltage schedule under Base Case (N-0) conditions, or whether this would be the same as the generator underexcited operation limit. R3.3.3?For all Transmission lines, studies shall consider relay loadability and identify how loadability is analyzed in the steady state simulation. The above wording needs to be changed, as the intent of this sentence is unclear, whether the intent is that Transmission Planners ensure that relay loading limits are included in the facility ratings, or whether this reflect some rule of thumb, such as 130% of conductor rating. In Requirement R3.3.4, it is suggested adding the words "and switched" to capacitors and reactors: Simulate the expected operation of existing and planned devices designed to provide Steady State control of electrical system quantities. These devices include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

Response: R3.1: The SDT agrees and has modified the requirement.

R3.1 Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4.

R3.3.2: The SDT has changed the wording to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world.

R3.3.2 Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis

R3.3.3 Ensure relay loadability limits are respected.

R3.3.4: The SDT agrees and has revised the wording to read “and switched capacitors and inductors”.

R3.3.4 Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

Organization	Question 3 Comment
Manitoba Hydro	R3.1: The requirement text should be changed to read “studies shall be performed for Planning Events to determine whether the BES meets the performance requirements in Table 1 based on the contingency list of events created in Requirement R3.4. . R3.2: Requirement wording should be similar to R3.4 for consistency. R3.4 & R3.5: The selection of the contingency list is based on the knowledge of the PC/TP. How do you produce “an explanation

Organization	Question 3 Comment
	of why the remaining Contingencies would produce less severe System results. without proving this with a study? If the explanation is "that based on engineering judgment, the remaining contingencies would produce less severe system results" then the explanation is implied and not necessary. VSLs: Under the moderate to severe VSL, the performance requirements currently refer to P2 through P7. We believe this is a typo and should be P1 through P7.
Response: R3.1: The SDT agrees and has modified the requirement. **R3.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4. R3.2: The SDT has revised the requirement. **R3.2** Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, part 3.5. R3.4 & R3.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results". **R3.4** Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted. VSL: The VSL matrix is correct. No change made.	
LCRA Transmission Services Corporation	In R3.3.4, what is meant by the term "electrical system quantities"? Quantities is typically an amount and its use here would indicate that a term such as parameters would be better suited.
Response: R3.3.4 Checking a few dictionary definitions: parameter: "an expression, a constant or variable whose value determines the specific form of the expression; one of an independent variable in a set of parametric equations; whereas quantity is defined as: an exact or specified amount or measure; that property by virtue of which is measurable; extent; measure, size, any amount. It appears that "quantities" is the better choice. No change made.	
National Grid	R3 Comment "Planning Assessment" and "shall perform analysis" are contradictory. R3 and its sub-requirements then reference study requirements. If this is an assessment, then the standard shouldn't be requiring a study.R3.1 Comment ? A. It is not clear what should be included in the list related to R3.4. Events P0 through P4 should include analysis of all BES facilities for which the Transmission Planner is responsible. Events P5 and higher should be limited to contingency events

Organization	Question 3 Comment
	that are deemed the most significant by the Transmission Planner. B. R3.1 refers to "lists". Is R3.4 creating one list or multiple lists" Suggest changing "lists" to "list" R3.2 Comment - Since R3.4 and R3.5 both require the responsible entity to create a list, the words in R3.2 be should be revised to be more similar to the words in R3.1. Suggest changing "Studies shall be performed to assess the impact of the Extreme Events identified in Requirement R3.5. to "Studies shall be performed to assess the impact of the Extreme Events, which are identified by the list created in Requirement R3.5. R3.3.2 Comment " A. Traditionally transmission planners have used their judgment about the minimum steady state voltage limitations of generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. B. Voltage limitations are for both minimum and maximum. If this requirement is kept, then "minimum" should be deleted. C. Is this requirement really looking at "voltage limits" or generator "reactive capability"? R3.3.3 - This requirement should be deleted. Each reliability issue should be addressed in one standard and relay loadability is addressed in PRC-023. If requirements of PRC-023 are met, the relay loadability does not constitute a limitation. If this requirement is intended to apply to modeling relay characteristics in stability simulations, which is not addressed by PRC-023, then the requirement should be more explicit. However, as written it appears that the intent was to be in-line with Blackout Recommendation 8a which relates to steady-state loadability, which is covered by PRC-023. R3.4 Comment - Table 1 includes both Steady State and Stability events. R3.4 needs to indicate that it only applies to the Steady State portion of the Table. R3.5 Priority Comment ?It is recommended that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences and the requirements are too vague to have auditable value. If the requirement is not deleted, the following is recommended:- Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events. If not, it will be difficult to utilize the results to obtain projects approvals.- It should be clear that an evaluation does not require solution development for all Extreme Events- Change "an evaluation of possible actions"? to "where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered. – The statement "and shall include an explanation of why the remaining Contingencies would produce less severe System results" is too open and should be deleted. Violation Severity Levels:R3.4 Since this is a binary requirement, should this have a Severe VSL? R3.5 Since this is a binary requirement, should this have a Severe VSL?

Response: R3: The SDT agrees that use of studies and analyses can be confusing and has changed the wording to provide greater clarity.

R3 For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, parts 2.1, and 2.2. The studies shall be based on computer simulation models using

Organization	Question 3 Comment
	data provided in Requirement R1. R3.4: Requirement R3, part 3.4 has been revised to indicate that the Planning Coordinator/Transmission Planner is to produce a Contingency list, of those planning events that are expected to produce more severe results on its portion of the BES. The Planning Coordinator/Transmission Planner is required to identify the Contingency list to be studied and provide the rationale as to why these Contingencies are expected to produce more severe results. There is no requirement to include all BES facilities for P0 to P4. No change made. R3.1: The SDT has changed "lists" to "list". **R3.1** Studies shall be performed for Planning Events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4. R3.2: The SDT has revised the wording of the requirement. **R3.2** Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, part 3.5. R3.3.2: The SDT agrees that judgment is used today. There is a project (PRC-024) that will address this issue. The SDT has changed the wording to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and that they are being treated within the simulation as they will react in the real world. The word minimum was retained as the intent is to address low voltage ride through. No change made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. R3.4: Although Table 1 includes both steady state and stability events, Requirement R3 is "for the steady state portion of the Planning Assessment.."; so there is no need for adding further clarification in Requirement R3, part 3.4. No change made. R3.5: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the PC/TP with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event. The need to identify possible actions addresses an Order 693 directive. Your suggested wording would make identification of possible actions optional. No change made. Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the Contingencies selected are those to produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining contingencies would produce less severe System results". **R3.4** Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed

Organization	Question 3 Comment
to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted. VSLs: The VSLs for Requirement R3, parts 3.4 & 3.5 are required elements of the primary requirement. The VSLs categorize noncompliance with the requirement, "in total" – not with each of the individual parts of the requirement. No change made.	
Entergy Services, Inc	In R3.5 what would constitute "an evaluation of possible actions designed to reduce?" R3 should be broken into two pieces where the near term portion could be a Medium VRF but the long term section should be a Low VRF. Violations occuring in the longer term horizon are subjective and assumptions concerning future plans too broad to justify a Medium VRF. In Requirement R3.1, it is suggested that the word "contingency" be added to describe the lists created in R3.4.
Response: R3.5: In the event that an extreme event causes cascading outages, the "possible actions" would be the possible actions that would reduce the likelihood or mitigate the consequences and adverse impacts of the event". VRF: The SDT believes that all of the steady state responses are equally important. No change made. R3.1: The SDT agrees and has revised the wording. **R3.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4.	
Great River Energy	R3.3.3 The relay loadability section needs better definition. Is this identifying that: if the relay load limit is the most Limiting Element of a transmission line how it would be handled if it is overloaded considering that there may be some margin before opening the line and/orif the line reaches a certain overload level based on a non-Relay Load Limit being the Most Limiting Element that the relay load limit should be analyzed to see if it will actually activate an opening of the transmission line or the planners need to review all of the relays associated with all transmission lines within the model and indicate if loadability is a concern for each contingency analyzed. There are a lot of lines, (probably the majority), that have not defined a relay capability within the rating fields of the model! This would seem to be a FAC-009 issue. As a discussion point on R3.3.3, it would seem that relay loadability should be addressed in FAC-009 and the Model Building process. Putting this burden in the planning assessment will be difficult to determine if the Most Limiting Element within the model is not a relay load limit as those parameters typically are not the Most Limiting Element. Every line in the model may need to be defined as to what its relay loadability is to meet this requirement. Our regional model build reports a Most Limiting Element, a short term emergency level, and a long-term emergency for the three ratings available within the model. It would seem that the long-term emergency field should be replaced with a Relay Load Limit value such that the R3.3.3 would not be as great of a burden on the planner.
BC Hydro	R3.3.3: Consider changing it to read, "Demonstrate that, for all Transmission lines, relay loadability standards are met in accordance with the PRC series of standards"
Response: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections and to	

Organization	Question 3 Comment
ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected.	
Midwest ISO	Opening Remarks. Specific Comments for Requirement 3:A) Under R3, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R3 only says "Long-term Planning". By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: "Near-Term and Long-Term Transmission Planning". B) Under R3.1 the "Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the lists created in the Requirement 3.4". We believe that the following language will improve this requirement: Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the more severe contingency lists created in the Requirement 3.4. C) Under R3.3.2 the Midwest ISO generally agrees with FirstEnergy's comments on this. D) Under R3.3.3 the Midwest ISO feels that this sub-requirement is redundant with PRC-023-2 and therefore we feel that this sub-requirement needs to be removed and replaced with our suggested bullet language under R1.1.2 ? Relay Loadability Limitation (see F on page 3 of 9 above) E) Under R3.4 to make this requirement clearer, please add the following language between the words "expected to" in the first sentence: "expected by the assessing entity to" We believe that this language addition improves the clarity of this requirement. The first sentence would then read: Those Planning Event Contingencies in Table 1 that are expected by the assessing entity to produce more severe System impacts shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created. F) Under R3.5 to make this requirement clearer, please add the following language between the words "expected to" in the first sentence: "expected by the assessing entity to" We believe that this language addition improves the clarity of this requirement. The first sentence would then read: Those Extreme Events in Table 1 that are expected by the assessing entity to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3.2 created.
Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made. **Mitigation Time Horizon** The time horizons available for mitigating a violation to a requirement include the following: • **Long-term Planning** — a planning horizon of one year or longer. • **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.	

Organization	Question 3 Comment
• **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time. • **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system. • **Operations Assessment** — follow-up evaluations and reporting of real time operations. R3.1: The SDT has modified the requirement. **R3.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, part 3.4. R3.3.2 The SDT has changed the wording to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. **R3.3.3** Ensure relay loadability limits are respected. R3.4 & R3.5: The Planning Coordinator/Transmission Planner are the applicable entities for this standard, so adding "by the assessing entity" is redundant. No change made.	
PJM	In R3, why require a Planning Coordinator AND a Transmission Planner to perform this analysis? Isn't this a duplication of effort? R3.4 should come before R3.1. You should never reference down in a standard. Please present the items in the order in which they should be performed/considered. R3.5 should come before R3.2. You should never reference down in a standard. Please present the items in the order in which they should be performed/considered. R3.3.2 should be broken into two requirements since two separate tasks need to be performed. R3.3.3 should be broken into two requirements since two separate tasks need to be performed. Also in R3.3.3, analysis of relay loadability will require the inclusion of all relay models 200 kV and above. This information is not presently gathered by the ERAG MMWG for the Eastern Interconnection. To help with compliance, questions R3.3.4 needs more specificity. Maybe define a minimum percentage of total possible contingencies as a bright line whether you have performed enough more severe contingencies. Would expect a number between 10 and 25 percent. R3.4 should be broken into two requirements since two separate tasks need to be performed. To help with compliance questions, R3.3.5 needs more specificity. Maybe define a minimum percentage of total possible contingencies as a bright line whether you have performed enough more severe extreme contingencies. Would expect a number

Organization	Question 3 Comment
	between 10 and 25 percent. R3.5 should be broken into three requirements since three separate tasks need to be performed.
Response: R3: The SDT believes that the requirement belongs to both the Planning Coordinator and the Transmission Planner. No change made. R3.4 & R3.5: The SDT disagrees. No change made. R3.3.2: The SDT sees this as only one requirement to identify how the generators are analyzed. No change made. R3.3.3: The SDT sees this as only one requirement to identify how the relay loadability is analyzed. No change made. R3.3.3: The SDT has clarified the requirement to ensure all relay loadability limits are respected in the analysis. R3.3.4: The number of Contingencies is system specific and any percentage that the SDT would establish would be wrong for some entities. No change made. R3.4: The SDT disagrees as the tasks are related. No change made. R3.3.5: The number of Contingencies is system specific and any percentage that the SDT would establish would be wrong for some entities. No change made R3.5: The SDT disagrees as the tasks are related. No change made.	
Brazos Electric Cooperative	R3.4 and 3.5 give us a concern. Table 1 identifies a number of events that are to be assessed but requiring an explanation of why certain events would produce less severe results seems to be open ended thus making it hard to audit. If all the events in Table 1 are studied or have been studied in the past then what is one supposed to document? we understand this is to allow the planner a certain amount of flexibility in their analysis but it seems counter to the idea of requiring a review of all the events in Table 1. We don't have any suggested wording changes, just passing along a general idea.
Response: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".	
American Electric Power	With regard to R3.3.3., please include transformers as relay loadability also applies to transformers.
Response: The SDT has clarified the requirement to ensure relay loadability limits are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected.	
ITC Holdings	Comments: If the SDT feels that a requirement such as R3.3.4 is necessary, it may also be necessary to identify further limitations on the use of the control devices referred to. For example, a manually controlled phase shifter would require a time period, or loading limits, to readjust flows to limit a post-contingency flow if not pre-set in the pre-contingency state. Similarly, a tap-changing transformer also requires an adjust period for voltage control. We suggest adding a statement to this requirement (or somewhere in performance requirements) that "all post-contingency flows/voltages must remain within the applicable facility ratings before,

Organization	Question 3 Comment
	during, and after the use of such control devices.
Response: The SDT has revised the requirement wording to clarify that the intent is to simulate automatic operation of existing and planned devices. **R3.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.	
Northern Indiana Public Service Company	R3.3.3: Evaluation of loadability should be triggered only for those circuits with new protection settings issued since the last assessment; evaluation of circuits that have not been newly assigned or re-assign protection settings is a misuse of resources.
Response: The SDT has clarified the requirement to ensure all relay loadability limits are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected.	
Minnesota Power	A) Under R3, the Time Horizon of the TPL standards is intended for years one through 10; however, the Time Horizon shown in R3 only says “Long-term Planning”. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: “Near-Term and Long-Term Transmission Planning”. B) R3.3.3 Is this sub-requirement redundant with PRC-023-2? Is it covered in FAC-009? We believe the SDT should review these standards and if it is a redundant requirement, then this sub-requirement needs to be removed. C) Under R3.4 to make this requirement clearer, please add the following language between the words “expected to” in the first sentence: “expected by the assessing entity to”? We believe that this language addition improves the clarity of this requirement. The first sentence would then read: “Those Planning Event Contingencies in Table 1 that are expected by the assessing entity to produce more severe System impacts shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3.1 created. D) Under R3.5 to make this requirement clearer, please add the following language between the words “expected to” in the first sentence so that the phrase reads: “expected by the assessing entity to”? We believe that this language addition improves the clarity of this requirement. The first sentence would then read: “Those Extreme Events in Table 1 that are expected by the assessing entity to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3.2 created.
Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made. **Mitigation Time Horizon** The time horizons available for mitigating a violation to a requirement include the following:	

Organization	Question 3 Comment
• **Long-term Planning** — a planning horizon of one year or longer. • **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal. • **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time. • **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system. • **Operations Assessment** — follow-up evaluations and reporting of real time operations. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections. **R3.3.3** Ensure relay loadability limits are respected. R3.4& R3.5: The Planning Coordinator/Transmission Planer are the applicable entities, so adding "by the assessing entity" is redundant. No change made.	
LADWP	R3.4 This requirement is very strange. If there is a known planning event that is more severe than those listed in Table 1, it should be so identified in Table 1. It is not fair to ask every planner to search for more severe contingencies without any specifics. R3.4 should be deleted. R3.5 This is similar to R3.4; this requires proving of null set. The only way this requirement can be met is to perform an exhaustive and unlimited list of extreme event, real or imaginery, before a rationale can be rendered. This requirement should be deleted with the exception of the last sentence regarding "cascading outages.
Response: R3.4: Requirement R3.4 has been revised. The intent is not to identify additional Contingencies in addition to the planning events in Table 1, but to identify those Table 1 planning events that are expected to be more severe for your portion of the BES. Based on industry comments, the SDT has deleted the requirement to provide an explanation of "why the remaining Contingencies would produce less severe System performance". **R3.4** Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. R3.4 & R3.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the Contingencies selected are those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results". **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.	
Platte River Power Authority	R3.3.3. Zone 3 type relay loadability studies (single and multiple contingency analyses) should be performed in the OPERATING HORIZON to provide results flagged for possible problems to the Relay Engineers who will evaluate a relay setting change on an Facility or a modification to a relay setting for a new Facility about to be put in-service. I do not see the value of Zone 3 relay

Organization	Question 3 Comment
	loadability checks in the Planning Horizon.
Response: The SDT does not agree that relay loadability should be limited to the Operating Horizon. The SDT has clarified the requirement to ensure relay loadability limits are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected.	
MAPPCOR	R3.3.2 - Traditionally transmission planners have used their judgment about the minimum steady state voltage limitations of generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R3.3.3 - PRC-023 requires relay loadability to be reflected in facility ratings. Therefore this additional requirement is unnecessary and should be deleted. R3.4 is there a measure for what is a “more severe system impact”? R3.5 Recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:-Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events-It should be clear that an evaluation does not require solution development for all Extreme Events-Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered.
Response: R3.3.2: The SDT agrees that judgment is used today. There is a project (PRC-024) that will address this issue. The SDT has changed the wording to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT believes that the requirement is necessary for the TPL standard and has clarified the requirement in an attempt to remove the objections **R3.3.3** Ensure relay loadability limits are respected. R3.4: Requirement R3, part 3.4 requires the Planning Coordinator/Transmission Planner to prepare a list of planning event Contingencies that, in the Planning Coordinator’s and Transmission Planner’s judgment, are expected to produce more severe System impacts, and to document the rationale for the Contingencies selected. The documented rationale provided by the Planning Coordinator/Transmission Planner will define what is considered to be the more severe System impacts relative to the Contingencies not selected because they are expected to be less severe. No change made. R3.5: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, the SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event. The need to identify possible actions addresses an Order 693 directive. Your suggested wording would	

Organization	Question 3 Comment
make identification of possible actions optional. No change made.	
Orlando Utilities Commission	For Requirement 3.3.1 and 3.3.4 I suggest adding language similar to 3.3.2 and 3.3.3 establishing that “studies shall consider” rather then requiring every simulation precisely recreate this usually minor part of system performance. These devices generally do not respond except for a nearby event, and even then their response is rarely such that it would make the situation “worse”. The effect of these devices must be considered, but mandating that every simulation faithfully reproduce the response of every device is not only an efficient way to do this, it actually provides a counter incentive to going above and beyond the standard requirements. Any simulation used to meet this standard that failed to precisely reproduce the performance of this equipment would be a violation of this requirement (as currently written). As such there is no incentive for an entity to include anything but the absolute minimum number of simulations required to meet the standard, since each extra simulation represents an opportunity to miss this requirement. Good planning is based on running a broad range of events against a broad range of conditions and evaluating those responses against a set of performance criteria. This is encouraged by requiring that studies consider the response of equipment to these events rather then mandating their precise reproduction in simulation.
Response: R3.3.1: The SDT disagrees with the comment as the intent of Requirement R3, part 3.3.1, consistent with Order 693, is to perform the simulation to reflect how the Protection System will operate in the real System for each Contingency without operator intervention. No change made. R3.3.4: The SDT disagrees with your comment. The simulation of the expected operation of devices such as phase-shifting transformers, load tap changing transformers ,etc. impacts post-Contingency the performance of the System. No change made.	
American Transmission Company	We propose the following comments for R3.Revise the R3.3.2 text to clarify that subsequent analysis is performed on generators whose voltages are expected to fall below the minimum voltage limits. We suggest this text: Consider the minimum steady state voltage limitations of all generators and identify how generators with bus voltages below its minimum voltage limits are analyzed in the subsequent steady state simulations. Revise the R3.3.3 text to more clearly relate to the specific requirements in PRC-023. We suggest this text: “Incorporate relay loadability per PRC-023 and identify how relay loadability is analyzed in the steady state simulation. Add R3.3.5. The obligation to consider only planned System adjustments that are executable should be a Requirement, rather than performance note “e” in the Planning Events, Steady State & Stability section of Table 1. We suggest this text: “Consider planned System adjustments, such as Transmission configuration changes and redispatch of generation, that are executable within the time duration of the applicable Facility Ratings.
Response: R3.3.2: The SDT has changed the wording to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected.	

Organization	Question 3 Comment
R3.3: The SDT disagrees as such planned System adjustments are considered to be operator corrective actions as opposed to automatic actions considered in Requirement R3, part 3.3. No change made.	
Idaho Power	R3.3.2 is unclear as drafted. The minimum steady state voltage limitation for synchronous generators is not a very meaningful value. All generators with an automatic voltage regulator will maintain the set point voltage until the VAR capability of the generator is exceeded, and then the voltage will deteriorate. R3.5 -The requirement to explain why remaining Extreme Contingencies would produce less severe System results than the ones selected for study is overly burdensome. The first part of the requirement requires identification of events that produce more severe System impacts. The reason the others were not selected is because they were less severe or non-credible. Listing all possible extreme events could result in a limitless list.
Response: R3.3.2: The SDT has changed the wording to clarify the intent of the requirement. For this standard, all that is required is to identify the assumptions concerning voltage limitations of the unit and ensure they are being treated within the simulation as they will react in the real world. **R3.3.2** Trip generators where simulations show generator bus voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. R3.5: Several industry commenters have indicated that an explanation of “why the remaining Contingencies would produce less severe System performance” should be deleted since the Contingencies selected are those to produce more severe System performance. The SDT agrees and has deleted the requirement for an “explanation of why the remaining contingencies would produce less severe System results”. **R3.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R3, part 3.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.	
New York Independent System Operator	R3.5. - The Extreme Events testing in Table 1 should be removed from this standard since there is no requirement to develop a Corrective Action Plan to address unacceptable consequences and the requirements are very general or vague. At a minimum, testing should only be required for EHV facilities or facilities specified by the Regional Entity ? for example, NPCC designates facilities that can have consequences outside an area as bulk power system facilities.
Response: R3.5: extreme events: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event. No change made.	
Duke Energy	Revise M3 to include a reference to R6, since the allocation of responsibilities will directly affect the evidence which is to be provided.
Response: M3: The SDT disagrees. Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis required to meet	

Organization	Question 3 Comment
the requirements of the TPL standard and to the Corrective Action Plan developed as part of the assessment. The intent of this requirement is to clarify that TPL requirements can be met through joint or shared analysis. Coordinating and/or joint analysis does not alleviate the responsibility that all entities need to comply with the standard requirements. Therefore, the SDT sees no reason to link Requirement R3 directly to Requirement R6 (now Requirement R7) in the measure or anywhere else. The requirements stand by themselves and do not require such a linkage. No change made	
Independent Electricity System Operator	1. In our opinion, R3 as drafted is rather convoluted as it attempts to cover several objectives. Firstly, we recommend replacing “utilizing data in Requirement R1” with “developed in accordance with Requirement R1” both in the requirement and the VSLs. Secondly, is the main objective of R3 to ensure studies are conducted based on computer simulation utilizing data provided in Requirement R1? Or is it to ensure that this is done, and that all the other objectives are also fulfilled, for example: assessment of system performance (R3.1 and R3.5), conducting the analysis as specified in R3.2 and R3.3, identification of critical Planning Event contingencies (R3.4), etc. If it is the former, then not conducting studies based on computer simulation utilizing data provided in Requirement R1 alone should have a VSL of Severe. If it is the latter, then the requirement should be either: (a) Revised to place all supporting conditions in the subrequirements. As an example, R3 could be revised as follows:R3. The steady state analyses of the Near-Term and Long-Term Planning Assessment as stipulated in R2.1 and R2.2 shall be performed as follows:R3.1. Studies are conducted based on computer simulation utilizing data provided in Requirement R1;R3.2. Studies shall be performed to determine?. (the rest of the existing R3.1) R3.2. The existing R3.3, and so on.This way, not conducting studies based on computer simulation utilizing data provided in Requirement R1 will be “rolled up” to the VSLs for the main requirement, as is currently stated in the VSL table.Or(b) Restructure, if there are multiple main objectives in R3, to clearly have the main objectives in the main requirement, or split it into more than one main requirement.2. Based on the way R3 is written, we agree with the VRF, Time Horizon and Measure. However, we do have a difficulty with the VSL based on our comments above on the requirement, especially on the Moderate VSL for “The Transmission Planner or Planning Coordinator did not base its studies on computer simulations using models utilizing data provided in Requirement R1.
Response: Requirement R3 has been modified. **R3** For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. R3 is a single requirement and the SDT disagrees with the concept of splitting this up into separate requirements. No change made. The moderate VSL has been modified to align with the changes made to the wording of the requirement. **R3, moderate VSL**: The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.	
Kansas City Power & Light	R3.3.3: Relay loadability has no bearing beyond the near term horizon. Loadability is not determined several years out. R3.5 “ does this imply that mitigation plans must be implemented” If not, then this is highly subjective and the last sentence of this requirement should be deleted.

Organization	Question 3 Comment
Response: R3.3.3 The SDT does not agree that relay loadability should be limited to the near term horizon. The SDT has clarified the requirement to ensure relay loadability limits, as defined in the relay loadability standard, are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected. R3.5: extreme events: The SDT disagrees that the standard should mandate corrective actions for extreme events due to the low probability of these events. However, SDT believes that those extreme events that are expected to produce more serve System impacts should be analyzed to assess the extent of the impacts on the System to provide the Planning Coordinator/Transmission Planner with information to decide, where appropriate, if it is reasonable to provide some corrective actions to reduce the possibility or limit the consequences of an extreme event.	
ReliabilityFirst Corporation	R3- Throughout this requirement there is a mention of developing a contingency table. It will be nice that such a table is developed under MOD-010 and MOD-012 standard. ERAG can develop such a list as part of their base case development effort. R3.3.3- Suggest changing it to read “For all Transmission lines, studies shall consider relay loadability, if that is the limiting factor for line loading.” R3.3.4 The term “expected operation” is vague. Some of these devices have relays which cause them to automatically respond to system changes, others are controlled by an operator. In both cases, the devices are “expected” to be utilized. Given that operator controlled devices are less certain to be utilized, and may be delayed in being utilized. The expected operation needs to be studied differently for automated devices and those requiring operator interventions.
Response: R3: Requirements R3.4 & R3.5 place the responsibility of creating planning event and extreme event Contingency lists on the applicable entities, the Planning Coordinator and the Transmission Planner as owners, operators or users of the BES. The SDT believes that requirement to develop these Contingency lists of planning and extreme events expected to produce the most severe results, and the rationale for the selection of these events, is best left to the Planning Coordinator/Transmission Planner responsible for its portion of the BES. However, the SDT does not believe that the standard would preclude ERAG from playing a role in the development of these Contingency lists; however, the compliance responsibility will fall to the Planning Coordinator/Transmission Planner. R3.3.3: The SDT has clarified the requirement to ensure relay loadability limits are respected in the analysis. **R3.3.3** Ensure relay loadability limits are respected. R3.3.4: The SDT agrees and has added automatic to the requirement. **R3.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide Steady State control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.	

4. Requirement R4 – Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: The SDT has made numerous clarifying changes to the requirements due to industry comments. In addition, Requirement R4, part 4.3.3 has been added.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1.

4.1 Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4.

4.2 Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, part 4.5.

4.3 Contingency analyses shall be performed and:

4.3.2 Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.3 Simulate the impact of transient swings on Protection System operation for Transmission lines and transformers.

4.3.4 Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4 Those planning events in Table 1that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4, part 4.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1 The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5 Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R4, part 4.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

Footnote 2 Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria.

R4 VSL	The responsible entity did not identify planning events as described in Requirement R4, part 4.4 or extreme events as	The responsible entity did not perform studies as specified in Requirement R4, part 4.1 to determine	The responsible entity did not perform studies as specified in Requirement R4, part 4.1 to determine	The responsible entity did not perform studies as specified in Requirement R4, part 4.1 to determine that the BES meets the

	described in Requirement R4, part 4.5.	that the BES meets the performance requirements for one of the categories (P1 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R4, part 4.2 to assess the impact of extreme events. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.	that the BES meets the performance requirements for two of the categories (P1 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R4, part 4.3.	performance requirements for three or more of the categories (P1 through P7) in Table 1.

Organization	Question 4 Comment
Dominion - Electric Transmission	R4.4 - Dominion believes that creating a master list of all contingencies a planner must take is burdensome and provides no planning value. In addition the contingencies will vary based on the loading configuration and the specific study case. In general, we start out with the very worst contingencies. If these cause hard rotor swings, we know we will probably have to do most of the possible contingencies in the station until we get down to contingencies that do not swing the generator much. But if the swings are light, then that particular load/topology situation probably does not need in-depth exploration. Creating a master list could create unnecessary study. However, we do support a list of the extreme contingencies in R4.5.
Response: Requirement R4, part R4.4 does not require a master list of all possible contingencies. The requirement is to create a list of those Contingencies expected to produce more severe results. There is nothing that prevents you from modifying the list based on simulation results (e.g., hard rotor swings). No change made.	
Northeast Power Coordinating Council	R4.3.2 - Traditionally transmission planners have assumed that generators would ride through low voltages associated with Planning Events which is generally adequate for non-wind generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R4.5 Priority Comment ?We recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:- Extreme Event performance should be a consideration when developing Corrective Action Plans to

Organization	Question 4 Comment
	address Planning Events- It should be clear that an evaluation does not require solution development for all Extreme Events- Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered. For Requirements R4.4 and R4.5, what defines “more severe System impacts”?
Response: R4.3.2: There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. Requirement R4, part 4.3.2 requires you to include in the assessment how you analyzed voltage ride-through capability. If complete information on the ride-through capability is not available, then you should just document your assumptions regarding ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.5: The SDT considers extreme event testing to be an important part of the assessment and therefore will not delete it. The expectation for extreme event testing is that for major problems you will evaluate actions to reduce likelihood or mitigate consequences. The SDT believes the original words express this concept better than your suggested words. No change made. R4.4 and R4.5: The definition of "more severe impacts" is left to the engineering judgment of the Transmission Planner and Planning Coordinator.	
Transmission Planning	R4.3.2. COMMENT: The inability to survive a given low voltage transient is often dependent on motor performance within the generating facility’s auxiliary load distribution system and is not a specific relay setting. Determination of specific generating plant low voltage ride through capability requires extensive modeling of the plant distribution system and is outside the scope of this standard.
Response: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of a generating plant's distribution system. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	
SERC Engineering Committee Planning Standards Subcommittee	R4.1:In Requirement R4.1, it is suggested that the word "contingency" be added to describe the lists created in R4.4?Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created in Requirement R4.4. R4.4:Regarding Requirement R4.4, it is suggested that a rewording be considered such as described below:? For each category of the Planning Events in Table 1, those Planning Event Contingencies that are expected to produce more severe System impacts shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4.1 shall be created. The rationale for the Contingencies selected for evaluation shall be available as supporting information

<table>
<tr><th>Organization</th><th>Question 4 Comment</th></tr>
<tr><td></td><td>with an explanation of why the remaining Contingencies would produce less severe System results.

R4.3.2:R4.3.2 requires that voltage ride through capability be analyzed. It is not clear what should be analyzed (e.g. auxiliary loads, generator protection, generator capability, etc.) This requirement needs more clarity.

Footnote #3:Footnote #3 needs to be revised to include 2LG faults in addition to 3-Phase faults indicating that the SLG criteria is met.</td></tr>
<tr><td colspan="2">Response: R4.1: The SDT agrees and has added the word "Contingency".

4.1 Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4.

R4.4: The SDT agrees and has modified the wording similar to your suggested wording, however - due to other stakeholder comments, the phrase requiring an explanation was deleted from the revised standard.

4.4 Those planning events in Table 1that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4, part 4.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information

R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of a generating plant's distribution system. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this.

4.3.2 Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

Footnote #3 (now footnote #2): The SDT agrees and has modified the wording similar to your suggested wording.

Footnote 2 Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria.</td></tr>
<tr><td>Modesto Irrigation District</td><td>Comments: We believe that R4.3.1-R4.3.3 should be bullets under R4.3</td></tr>
<tr><td colspan="2">Response: R4.3.1-R4.3.3: The SDT disagrees as these are mandatory elements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. No change made.</td></tr>
<tr><td>OPUC</td><td>4. Requirement R4 ? Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Comments: A: R4.3 should be modified to become the requirement to conduct contingency analyses with R4.3.1 thru 3</td></tr>
</table>

Organization	Question 4 Comment
	presented as bullets there-under. B: R4.3.2 should clarify whether all relay protection must be modeled

Response: R4.3: The SDT disagrees as these are mandatory requirements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. However, R4.3 has been modified to read more like a requirement as shown below.

4.3 Contingency analyses shall be performed and:

R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this.

4.3.2 Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

Organization	Question 4 Comment
Bonneville Power Administration	Requirement R4 should be consistent with R3. Suggested edit for R4. - "For the Stability portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term Transmission Planning Horizon studies in Requirement R2.4. The studies shall be based on computer simulations using models developed from the data provided in Requirement R1." R4.1 should be clarified consistent with comments to R3.1. Suggested clarification for R4.1 - "Studies shall be performed to determine whether the BES meets the performance requirements in Table 1. A reduced set of contingencies can be simulated based on a list created in requirement R4.4." As currently drafted, R4.3 is not a requirement. Without the statements in R4.3.1-R4.3.3, R4.3 is simply a phrase. Sub-Sub-Requirements R4.3.1 through R4.3.3 should be bullets under R4.3, with the language in R4.3 modified so that it becomes the requirement to conduct contingency analyses that address the three resulting bullets. R4.3.2 ? it is not clear what is required to be modeled. Typically a generator may have 10 or more protective relays. Is the intent to model all relay protection? The existing commercial programs do not have sufficient models or capacity to do that for all generators in the system. Requirement R4.4 also needs to be clarified as follows: R4.4 - "A reduced list of Contingencies can be developed for System Performance evaluation in Requirement R4.1 that includes those Planning Event Contingencies that are expected to produce more severe System impacts based on system performance as required in Table 1. R4.5 ? We disagree with the requirement to explain why remaining Extreme Contingencies would produce less severe System results than the ones selected for study. The first part of the requirement requires identification of events that produce more severe System impacts. The reason the others were not selected is because they were less severe or non-credible. In any case, theoretically, there can always be a more severe Extreme Contingency than the one selected for study. For example, if the Extreme Contingency studied were simultaneous loss of 3 transmission lines with failure of redundant RAS, then

Organization	Question 4 Comment
	simultaneous loss of 4 lines with failure of 2 sets of redundant RAS would be more severe. Listing all possible extreme events could result in a limitless list.

Response: The wording in Requirement R4 has been made identical to that in Requirement R3.

> **R4.** For the Stability portion of the Planning Assessment, as described in Requirement R2, parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1.

R4.1: The intent is to run the contingencies developed in Requirement R4, part 4.4, not a reduced set of them. No change made.

R4.3: The SDT disagrees as these are mandatory elements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. However, Requirement R4, part 4.3 has been modified to read more like a requirement as shown below.

> **4.3** Contingency analyses shall be performed and:

R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require modeling of all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4.3.2 to clarify this.

> **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

R4.4: The intent of Requirement R4, part 4.4 is to identify and develop a list of Contingencies to be run. Your proposed wording does not capture that intent. No change made.

R4.5: Several industry commenters have indicated that an explanation of “why the remaining Contingencies would produce less severe System performance” should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an “explanation of why the remaining Contingencies would produce less severe System results”.

Organization	Question 4 Comment
MRO MRO NERC Standards Review Subcommittee	MRO NSRS proposes the following comments for R4:Add R4.3.3 text include relay loadability in the R4 (Stability) requirements to parallel R3.3.3 in the R3 (Steady State) requirement which would more clearly relate to the specific requirements in PRC-023. MRO NSRS suggests this text: “Incorporate relay loadability per PRC-023 and identify how relay loadability is analyzed in the dynamic simulation. In R4.3.4, MRO NSRS proposes limiting the scope to automatic devices and adding the notion of “including but not limited to”. MRO NSRS suggests R4.3.4 text of: “Simulate the expected automatic operation of existing and planned control devices including but not limited to generation exciter control and power system stabilizers, static VAR compensators, power flow controllers, and DC Transmission controllers.

Response: R4.3: The SDT agrees with the general idea and has added Requirement R4, part 4.3.3. However, Requirement R4, part 4.3.3 requires that you "Simulate the impact of transient swings on Protection System operation for Transmission lines and transformers" rather than creating a stability requirement for relay loadability. This requirement is more applicable to stability studies than a relay loadability requirement would be. Relay loadability is more of a steady state

Organization	Question 4 Comment
issue than a dynamic issue. **4.3.3** Simulate the impact of transient swings on Protection System operation for Transmission lines and transformers. R4.3.4: The SDT has added the word "automatic" into Requirement R4, part 4.3.4 such that it now reads as follows: **4.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.	
SERC Engineering Committee Reliability Review Subcommittee (RRS)	In R4, should the “and” in the first sentence actually be “or”?” Footnote #3 needs to be revised to include 2LG faults in addition to 3Phase faults indicating that the SLG criteria is met. In Requirement R4.1, it is suggested that the word "contingency" be added to describe the lists created in R4.4”Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created in Requirement R4.4. ? Regarding Requirement R4.4, it is suggested that a rewording be considered such as the following: For each category of the Planning Events in Table 1, those Planning Event Contingencies that are expected to produce more severe System impacts shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4.1 shall be created. The rationale for the Contingencies selected for evaluation shall be available as supporting information with an explanation of why the remaining Contingencies would produce less severe System results. ? R4.3.2 requires that voltage ride through capability be analyzed. It is not clear what should be analyzed (e.g. auxiliary loads, generator protection, generator capability, etc.) This requirement needs more clarity. ? R4.3.2 ? By in large, the industry does not have the input data or the methods to do this. It would seem necessary to have PRC-024 approved before this can be met. In R4.3.2, need guidance on how to consider minimum steady state voltage limitations.
Response: R4: Requiring the Planning Coordinator AND the Transmission Planner to perform analysis should not result in a duplication of effort. Requirement R6 (now Requirement R7) requires the two entities to agree on their individual and joint responsibilities. The SDT believes that ‘AND’ is the proper word rather than ‘OR’. Using ‘OR’ could be interpreted by one entity as not applying to them. No change made. Footnote #3 (now footnote #2): The SDT agrees and has made the suggested change. **Footnote 2** Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria. R4.1: The SDT agrees and has made the suggested change. **4.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4.	

Organization	Question 4 Comment
R4.4: The SDT agrees and has made the suggested change however - due to other stakeholder comments, the phrase requiring an explanation was deleted from the revised standard. **4.4** Those planning events in Table 1that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4, part 4.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require modeling of all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	
FirstEnergy Corp	Specific comments, Requirements of R4:A. R4.1: A space is needed between the text "Requirement and R4.4" which are run together in the requirement. B. R4.3.3: For readability we suggest inserting the word "may" in between "devices include". We agree with the stated Measures, VRF, Time-Horizon, Data Retention and VSL of requirement R4
Response: R4.1: The SDT has corrected this problem. **4.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4. R4.3.3: The SDT agrees and has made the suggested change. **4.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.	
TVA System Planning	In R4, should the "and" in the first sentence actually be "or"? R4.3.2 requires that voltage ride through capability be analyzed. It is not clear what should be analyzed (e.g. auxiliary loads, generator protection, generator capability, etc.) This requirement needs more clarity. By in large, the industry does not have the input data or the methods to do this. It would seem necessary to have PRC-024 approved before this can be met.
Response: R4: Requiring the Planning Coordinator AND the Transmission Planner to perform analysis should not result in a duplication of effort. Requirement R6 (now Requirement R7) requires the two entities to agree on their individual and joint responsibilities. The SDT believes that 'AND' is the proper word rather than 'OR'. Using OR could be interpreted by one entity as not applying to them. No change made. R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require modeling of	

Organization	Question 4 Comment
all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	
Exelon Transmission Planning	See comment in response to question 9 regarding the lack of definition related to the failure of a “single Protection System”.
Response: See response to question 9 comment.	
Southern Company	Generating unit stability should be separated from system stability like in previous drafts. R4.2 and R4.5 are both addressing the extreme events. However, R4.2 is referring to R4.5 while R4.5 is referring to R4.2. We suggest deleting the reference back to R4.2 which is in R4.5. A similar situation exists for R4.1 and R4.4.
Response: The majority of the industry believes that there should be no distinction between generating unit stability and System Stability. No change made. R4.2, R4.5, R4.1, R4.4: The SDT does not see any harm in having the cross referencing. No change made.	
United Illuminating Northeast Utilities ISO New England, Inc. Central Maine Power Company	R4.3.2 Priority Comment - Traditionally transmission planners have assumed that generators would ride through low voltages associated with Planning Events which is generally adequate for non-wind generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R4.5 Priority Comment ?We recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:- Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events- It should be clear that an evaluation does not require solution development for all Extreme Events- Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered.
Response: R4.3.2: There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. Requirement R4, part 4.3.2 requires you to include in the assessment how you analyzed voltage ride-through capability. If complete information on the ride-through capability is not available, then you should document your assumptions regarding ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.5: The SDT considers extreme event testing to be an important part of the assessment and therefore will not delete it. The expectation for extreme event testing is that for major problems you will evaluate actions to reduce likelihood or mitigate consequences. The SDT believes the original words express this concept better	

Organization	Question 4 Comment
than your suggested words. No change made.	
System Protection and Transmission Planning Department	Comments under R1 apply here as well. The requirement to "utiliz[e] data provided in Requirement R1" is redundant with MOD-012, and should be moved to MOD-012. To conform with R1, we suggest a phrase be inserted that requires model data used in Stability Studies used for Annual Assessments be consistent with data submitted under MOD-012.
Response: R4: MOD-012 does not require the data to be used for an assessment of the Transmission System. Therefore, the requirement to utilize data provided under Requirement R1 is needed in this standard. No change made. R4: Because Requirement R1 references the data provided under MOD-012, there is no need for a reference to MOD-012 in Requirement R4. No change made.	
PPL Energy Plus	It should be pointed out that Breaker Failure (i.e. fail to open) and Breaker Fault (internal fault in breaker) are two different events.
Response: Breaker failure and breaker fault are two different events and that is reflected by having two different designations for these events in Table 1 (P2.3 and P4). No change made.	
PacifiCorp Deseret Generation & Transmission SRP Arizona Public Service Co Southern California Edison Company Western Area Power Administration Pacific Gas and Electric Co, Puget Sound Energy, Inc. NV Energy San Diego Gas and Electric Co Tucson Electric Power Company	As currently drafted, R4.3 is not a requirement. Without the statements in R4.3.1-R4.3.3, R4.3 is simply a phrase. Sub-Sub-Requirements R4.3.1 through R4.3.3 should be bullets under R4.3, with the language in R4.3 modified so that it becomes the requirement to conduct contingency analyses that address the three resulting bullets. R4.3.2 - it is not clear what is required to be modeled. Typically a generator may have 10 or more protective relays. Is the intent to model all relay protection? The existing commercial programs do not have sufficient models or capacity to do that for all generators in the system. R4.5 ? We disagree with the requirement to explain why remaining Extreme Contingencies would produce less severe System results than the ones selected for study. The first part of the requirement requires identification of events that produce more severe System impacts. The reason the others were not selected is because they were less severe or non-credible. In any case, theoretically, there can always be a more severe Extreme Contingency than the one selected for study. For example, if the Extreme Contingency studied were simultaneous loss of 3 transmission lines with failure of redundant RAS, then simultaneous loss of 4 lines with failure of 2 sets of redundant RAS would be more severe. Listing all possible extreme events could result in a limitless list.
NorthWestern Corporation NorthWestern Energy (NWE)	R4.3 is unclear. Requirements R4.3.1 through R4.3.3 should be bullets under R4.3, with R4.3 modified so that it becomes the requirement to conduct contingency analyses that address the three resulting bullets

Organization	Question 4 Comment
(NWMT)	R4.3.2 is unclear. It appears to be a broken sentence. Typically a generator may have 10 or more protective relays. Is the intent to model all relay protection? The existing commercial programs do not have sufficient models or capacity to do that for all generators in the system. It is our understanding that the voltage ride through standard is not complete at this time. R4.5 needs to be modified. It would be better to combine R4.2 and R4.5. The first part of the requirement requires identification of events that produce more severe System impacts. The presumed reason that the other contingencies were not selected is because they were less severe or non-credible. In any case, theoretically, there can always be examples of more severe Extreme Contingencies than the one selected for study. This can be achieved by simply choosing events that are even less credible. For example, if the Extreme Contingency studied was a simultaneous loss of 3 transmission lines with the failure of redundant RAS (SPS), then an event resulting in the simultaneous loss of 4 lines with the failure of 2 sets of redundant RASs would be even more severe. Listing all possible extreme events could result in a limitless list.
Response: R4.3: The SDT disagrees as these are mandatory elements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. However, Requirement R4, part 4.3 has been modified to read more like a requirement as shown below. **4.3** Contingency analyses shall be performed and: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require modeling of all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".	
Western Area Power Administration	R4.3.3 need not include the operation of exciters and power system stabilizers as modeling of these parts of a generation system is already covered in Mod-12 & Mod-13 Standards and therefore are inherent in the dynamic analysis conducted using a program such as the GE PSLF or PTI power system simulation programs.
Response: R4.3.3: MOD-012 and MOD-013 do not require the data to be used for an assessment of the Transmission System. Therefore, the requirement to simulate the operation of exciters and stabilizers is needed in this standard. No change made.	
Tampa Electric	Clarification needed on modeling of protection system equipment.
Response: Requirement R4, parts 4.3.1 and 4.3.2 do not require modeling of Protection System equipment. It just requires you to have simulations which include the effect of Protection System equipment operation. You don't have to specifically model a relay to simulate the effect of clearing a fault at 3 cycles. No change made.	

Organization	Question 4 Comment
Florida Reliability Coordinating Council, Inc - Transmission Working Group	R4.3.1 - Please clarify, is the intent of this requirement to have every relay modeled? We suggest clarifying that the intent is that Protection System Equipment would be incorporated into the contingency list, and that modeling the Protection System equipment settings and logic would only be done for Protection Systems that could significantly impact stability response (e.g., out-of-step relaying) as deemed appropriate through engineering judgment, and that the intent would be to do this only for the Region under study and not the entire Interconnection (e.g., studies in Florida should not need to include relays in Canada). R4.4 & R4.5 - Does the intent of allowing this “More severe events” to establish actual study parameter extend between the planned events and extreme events (e.g. if a range of extreme events establishes that planning events performance requirements are met, would a redundant analysis of the planning events still be required)
Response: Requirement R4, part 4.3.1 does not require modeling of Protection System equipment. It just requires you to have simulations which include the effects of Protection System equipment operation. You don't have to specifically model a relay to simulate the effect of clearing a fault at 3 cycles. If you need to model a relay to capture its effect, then model that relay. And certainly engineering judgment should be used to determine which relay effects should be included in the simulations. No change made. R4.4 and R4.5: You can always demonstrate that performance requirements are met by meeting them for a more severe Contingency. It is possible that you could demonstrate that performance requirements are met for planning events by performing extreme events (e.g., using a three-phase fault with stuck breaker Contingency can demonstrate that performance requirements for a single phase fault plus stuck breaker contingency is met). No change made.	
FMPA	R4.2, see comment on R3.3 concerning how to model a hurricane event or other weather event. R4.3, contingency analysis ought to specifically exclude studying contingencies on neighboring systems since stability is more related to protection system and clearing times. R4.3.1, please clarify, is the intent of this requirement to have every distance relay in each Interconnect modeled? We suggest clarifying that the intent is that Protection System Equipment would be incorporated into Facility Ratings and the contingency list, and that modeling the Protection System equipment settings and logic would only be done for Protection Systems that could significantly impact stability response (e.g., out-of-step relaying) as deemed appropriate through engineering judgment, and that the intent would be to do this only for the Region under study and not the entire Interconnection (e.g., studies in Florida should not need to include relay models in Canada). R4.3.2, we assume that the intent of this requirement would be to help establish the magnitude and duration of acceptable post-transient voltage dips, presumable to meet the curve published in the PRC-023 standard under draft. Is this a correct assumption? We assume the drafting team does not expect models to be written for every generator to actually model potential loss of station service due to voltage dips and automatically model potential generator trips. R4.4 and R4.5, see comments on R3.4 and R3.5 about re-arranging these requirements.
Response: R4.2: There are no hurricane events or weather events in the extreme events for stability analysis. No change made. R4.3: The SDT disagrees. There may be some contingencies on external systems which can have a dynamic impact on the system under study. Part 4.4.1 has been added to Requirement R4 to address this possibility.	

Organization	Question 4 Comment
4.4.1 The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list. R4.3.1: Requirement R4, part 4.3.1 does not require modeling of Protection System equipment. It just requires you to have simulations which include the effects of Protection System equipment operation. Certainly engineering judgment should be used to determine which relay effects should be included in the simulations. No change made. R4.3.2: The intent of this requirement is to include in the Planning Assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of a generating plant's distribution system. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the Planning Assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4 and R5: The SDT does not agree that the requirements should be re-ordered. No change made.	
MidAmerican Energy Company	MidAmerican commends the SDT for its hard work on this standard. MidAmerican suggests that R4.5 be revised by changing “remaining Contingencies” to “remaining unselected Contingencies.
Response: R4.5: Several industry commenters have indicated that an explanation of “why the remaining Contingencies would produce less severe System performance” should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an “explanation of why the remaining Contingencies would produce less severe System results”. **4.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R4, part 4.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.	
SMUD	R4.3:R4.3.2 - The requirement is unclear. If it is to cover modeling issues, then it should be under MOD series. If it is to cover voltage ride through performance, then performance metrics should be provided. R4.5Listing all possible scenarios for studying extreme contingencies will result in a limitless list. Discretion should be given to the transmission planner on the selection of the contingencies without a requirement to list why other extreme contingencies have not been included.
Response: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of a generating plant's distribution system. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this.	

Organization	Question 4 Comment
4.3.2 Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".	
Progress Energy Florida, Inc.	For R4.3.2, PEF assumes that the SDT understands that the extent of analyzing generation voltage ride-through capability does not extend to modeling of individual inductive loads on the Distribution side, as this does not fit the definition of the BES. Motor loads on the Distribution system do have an effect on generation voltage ride-through capability, however, and PEF therefore is perplexed as to what extent the SDT expects concerning analysis for this sub-requirement.
Response: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of a generating plant's distribution system. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	
Xcel Energy	R4.3 - requires very labor intensive and detailed studies to be conducted; there are concerns about being able to accomplish the required studies within the 24 month implementation period; additionally, while there may be some reliability benefit to requiring these studies, have the costs of this requirement been studied?; an alternative could be some sort of phased implementation (x% completed by 24months, etc.) R4.3.3 - to what degree is generator relaying factored into the model/study?
Response: R4.3: The SDT believes that 24 months is sufficient to perform the additional studies. No change made. R4.3.3: Generator relaying is not a part of Requirement R4, part 4.3.3.	
Ameren	In Requirement R4.1, it is suggested that the word "contingency" be added to describe the lists created in R4.4Studies shall be performed to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists created in Requirement R4.4. Regarding Requirement R4.4, it is suggested that a rewording be considered such as described below:For each category of the Planning Events in Table 1, those Planning Event Contingencies that are expected to produce more severe System impacts shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4.1 shall be created. The rationale for the Contingencies selected for evaluation shall be available as supporting information with an explanation of why the remaining Contingencies would produce less severe System results.

Organization	Question 4 Comment
	R4.3.2 requires that voltage ride through capability be analyzed. It is not clear what should be analyzed. e.g. auxiliary loads, generator protection, generator capability, etc. We would like to see more clarity on this requirement. It seems that the stuck breaker scenarios would always be more severe than the internal breaker failure scenario since they would be clearing in delayed clearing time and thus make P2.3 redundant. Are there is some question on whether P3 contingencies would be necessary for stability analysis. Revise wording in VSL from “categories” to “applicable categories”. e.g. some entities may not have common tower facilities and thus there would be no P7 category contingencies to evaluate. Footnote #3 needs to be revised to include Double-Line-To-Ground faults in addition to Three-Phase faults indicating that the SLG criteria is met.

Response: R4.1: The SDT agrees and has added the word "Contingency".

> **4.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4.

R4.4: The SDT agrees and has modified the wording similar to your suggested wording however - due to other stakeholder comments, the phrase requiring an explanation was deleted from the revised standard.

> **4.4** Those planning events in Table 1that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R4, part 4.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of a generating plant's distribution system. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this.

> **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

Stuck breaker comment: A stuck breaker scenario would not always be more severe than an internal breaker fault. Depending on the location of CTs and PTs, an internal fault could take longer to clear.

P3 comment: Fault induced delayed voltage recovery simulations could be more severe in a Load area when a generator is out of service. Therefore, P3 events are applicable to Stability analysis.

VSL: The SDT does not believe it is necessary to add the word "applicable" in front of "categories" in the VSL for Requirement R4. The requirement in Part 4.1 is to study the list (Part 4.4) of "Those planning event Contingencies in Table 1 that are expected to produce more severe System impacts". If you have no applicable events in one of the categories, then just state that in the Planning Assessment. This will not be considered as not performing a study for one of the categories.

Organization	Question 4 Comment			
R4 VSL	The responsible entity did not identify planning events as described in Requirement R4, part 4.4 or extreme events as described in Requirement R4, part 4.5.	The responsible entity did not perform studies as specified in Requirement R4, part 4.1 to determine that the BES meets the performance requirements for one of the categories (P1 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R4, part 4.2 to assess the impact of extreme events. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.	The responsible entity did not perform studies as specified in Requirement R4, part 4.1 to determine that the BES meets the performance requirements for two of the categories (P1 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R4, part 4.3.	The responsible entity did not perform studies as specified in Requirement R4, part 4.1 to determine that the BES meets the performance requirements for three or more of the categories (P1 through P7) in Table 1.
Footnote #3 (now footnote #2): The SDT agrees and has modified the wording similar to your suggested wording. **Footnote 2** Unless specified otherwise, simulate Normal Clearing faults. Single line to ground (SLG) or three phase (3Ø) are the fault types, that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria.				
Manitoba Hydro	R4.1: The requirement text should be changed to read “studies shall be performed for Planning Events to determine whether the BES meets the performance requirements in Table 1 based on the contingency lists of events created in Requirement R4.4. R4.2: Requirement wording should be similar to R4.4 for consistency. R4.3: We agree that consideration of generator voltage ride through is important. However, we also suggest that frequency ride through capability be analyzed. R4.4 & R4.5: The selection of the contingency list is based on the knowledge of the PC/TP. How do you produce “an explanation of why the remaining Contingencies would produce less severe System results. without proving this with a study” If the explanation is “that based on engineering judgment, the remaining contingencies would produce less severe system results” then the explanation is implied and not necessary.			

Organization	Question 4 Comment
Response: R4.1: The SDT agrees and has changed the wording similar to your suggestion. **4.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4. R4.2: The SDT does not understand this comment. No change made. R4.3: Frequency ride-through for generators would only be needed for a limited number of simulations, and therefore the SDT does not see the need to make a general requirement for this. No change made. R4.4 and R4.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".	
LCRA Transmission Services Corporation	In R4.3.3, what is meant by the term "electrical system quantities"? Quantities is typically an amount and its use here would indicate that a term such as parameters would be better suited.
Response: "Electrical system quantities" are items such as voltage, current, power, etc. The SDT believes the use of this term is appropriate in Requirement R4, part 4.3.3 (now 4.3.4). No change made.	
National Grid	R4 Comment " "Planning Assessment" and "shall perform analysis" are contradictory. R4 and its sub-requirements, then reference study requirements. If this is an assessment, then the standard shouldn't be requiring a study. R4.1 Comment ? A. It is not clear what should be included in the list related to R4.4. Events P0 through P4 should include analysis of all facilities BES facilities for which the Transmission Planner is responsible. Events P5 and higher should be limited to contingency events that are deemed the most significant by the Transmission Planner. B. R4.1 refers to "lists". Is R4.4 creating one list or multiple lists? Suggest changing "lists" to "list" R4.2 Comment - Since R4.4 and R4.5 both require the responsible entity to create a list, the words in R4.2 be should be revised to be more similar to the words in R4.1. Suggest changing "Studies shall be performed to assess the impact of the Extreme Events identified in Requirement R4.5. " to "Studies shall be performed to assess the impact of the Extreme Events, which are identified by the list created in Requirement R4.5. R4.3.2 Priority Comment - Traditionally transmission planners have assumed that generators would ride through low voltages associated with Planning Events which is generally adequate for non-wind generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R4.5 Priority Comment ?It is recommended that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. If the requirement is not deleted, the following is recommended:- Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events. If not, it will be difficult to utilize the results to obtain projects approvals.- It should be clear that an evaluation does not require solution development for all Extreme Events- Change "an evaluation of possible

<table>
<tr><th>Organization</th><th>Question 4 Comment</th></tr>
<tr><td></td><td>actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered. - The statement “and shall include an explanation of why the remaining Contingencies would produce less severe System results” is too open and should be deleted.

Violation Severity Levels:R4.4 Since this is a binary requirement, should this have a Severe VS? R4.5 Since this is a binary requirement, should this have a Severe VSL?</td></tr>
<tr><td colspan="2">Response: R4: The SDT does not see a contradiction. Requirement R4 is a study requirement. The assessment requirement for stability is Requirement R2, part 2.4 and requires the use of current or past studies. No change made.

R4.1A: The SDT disagrees. P1 - P4 (P0 not applicable to Stability) should be run for those Contingencies expected to produce more severe results. It is not necessary to study faults on every line in the System. No change made.

R4.1B: The SDT agrees and has changed "lists" to "list".

4.1 Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4.

R4.2: The SDT agrees and has changed to your suggested wording.

4.2 Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, part 4.5.

R4.3.2: There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. Requirement R4, part 4.3.2 requires you to include in the assessment how you analyzed voltage ride-through capability. If complete information on the ride-through capability is not available, then you should document your assumptions regarding ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this.

4.3.2 Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

R4.5: The SDT considers extreme event testing to be an important part of the assessment and therefore will not delete it. The expectation for extreme event testing is that for major problems you will evaluate actions to reduce likelihood or mitigate consequences. The SDT believes the original words express this concept better than your suggested words. No change made.

R4.4 and R4.5 VSLs: The VSLs are based on taking Requirement R4 as a whole with Requirement R4, parts 4.4 and 4.5 being portions of that whole. The SDT does not think that failing to create a list of Contingencies should be a severe violation. When taking Requirement R4 as a whole, failing to create the list was deemed to be lower violations. No change made.</td></tr>
<tr><td>Entergy Services, Inc</td><td>In R4.5 what would constitute "an evaluation of possible actions designed to reduce?"?

R4.3.2 requires that voltage ride through capability be analyzed. It is not clear what should be analyzed (e.g. auxiliary loads, generator protection, generator capability, etc.) This requirement needs more clarity. “

R4.3.2 “ By in large, the industry does not have the input data or the methods to do this. It would seem necessary to have PRC-024 approved before this can be met.</td></tr>
</table>

Organization	Question 4 Comment
Response: R4.5: "An evaluation of actions designed to reduce" means looking for ways to reduce the probability of the event occurring or reducing the magnitude of the consequences of that event. For example, if a three phase fault with a bus differential failing to operate results in the collapse of a large Load area, a possible action would be to add a redundant bus differential relay. This reduces the probability of the event occurring. Or if a three phase fault with a stuck breaker results in a large area of the system pulling out of synchronism, an SPS could be used to trip a generator and keep the rest of the system in synchronism. This would reduce the magnitude of the consequences of the event. The evaluation would be comparing potential solutions and their cost with the consequences of the event to determine the best course of action to take (if any). R4.3.2: There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. Requirement R4, part 4.3.2 requires you to include in the assessment how you analyzed voltage ride-through capability. If complete information on the ride-through capability is not available, then you should document your assumptions regarding ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	
BC Hydro	Comments: Consider changing R4.3.2 to, "Confirm proper generator performance under anticipated conditions including low voltage ride-through capability" In R4.3.3, change "VAR" to "var". The IEC has adopted the name var, var (volt ampere reactive power), for the coherent SI unit volt ampere for reactive power. (see: http://www.iec.ch/zone/si/si_elecmag.htm#si_rpo). Is there an overlap between R4.3.3 and the MOD standards? If so, perhaps R4.3.3 should be deleted. If not, perhaps the MOD standard should be expanded to include this. Consider adding R4.3.4, "not simulate any operator intervention"
Response: R4.3.2: The SDT has changed the wording of Requirement R4, part 4.3.2 for additional clarification. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.3.3: The SDT agrees and has changed "VAR" to "var". **4.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers. R4.3.3: MOD-012 and MOD-013 do not require the data to be used for an assessment of the Transmission System. Therefore, the requirement to simulate the operation of exciters and stabilizers is needed in this standard. No change made. R4.3.4: The SDT does not think it is necessary to add "not simulate any operator intervention". If operator intervention is appropriate in the time frame of the study, then simulate it. No change made.	
Midwest ISO	Opening Remarks. Specific Comments for Requirement 4:

Organization	Question 4 Comment
	A) Under R4, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R4 only says "Long-term Planning". By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: "Near-Term and Long-Term Transmission Planning".
Minnesota Power	Under R4, the Time Horizon of the TPL standards is intended for years one through 10; however, the Time Horizon shown in R4 only says "Long-term Planning". By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: "Near-Term and Long-Term Transmission Planning".
Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made. **Mitigation Time Horizon** The time horizons available for mitigating a violation to a requirement include the following: • **Long-term Planning** — a planning horizon of one year or longer. • **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal. • **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time. • **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system. • **Operations Assessment** — follow-up evaluations and reporting of real time operations.	
PJM	In R4, why require a Planning Coordinator AND a Transmission Planner to perform this analysis? Isn't this a duplication of effort? R4.4 should come before R4.1. You should never reference down in a standard. Please present the items in the order in which they should be performed/considered. Also in R4.1, a space is needed between "Requirement" and -R4.4-. R4.5 should come before R4.2. You should never reference down in a standard. Please present the items in the order in which they should be performed/considered. In R4.2.3, I question whether the existing dynamics models can evaluate voltage ride through. If you are just talking about modeling voltage protection of generators then maybe, but this protection information is presently not collected by the ERAG MMWG for the Eastern Interconnection. R4.4 should be broken into two requirements since two separate tasks need to be performed. R4.5 should be broken into three requirements since three separate tasks need to be performed.

Organization	Question 4 Comment
Response: R4: Requiring the Planning Coordinator AND the Transmission Planner to perform analysis should not result in a duplication of effort. Requirement R6 (now Requirement R7) requires the two entities to agree on their individual and joint responsibilities. No change made. R4.4 & R4.5: The SDT does not believe that re-ordering the requirements serves any purpose. No change made. R4.1: The SDT has revised the requirement. **4.1** Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, part 4.4. R4.2.3: The SDT assumes you meant Requirement R4.3.2: There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. Requirement R4, part 4.3.2 requires you to include in the assessment how you analyzed voltage ride-through capability. If complete information on the ride-through capability is not available, then you should document your assumptions regarding ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.4: The SDT disagrees that this requirement should be broken into two requirements. There are not two independent tasks in the requirement. The tasks are inherently correlated and will be assessed as part of the primary Requirement R4. No change made. R4.5: The SDT disagrees that this requirement should be broken into three requirements. There are not three independent tasks in the requirement. The tasks are inherently correlated and will be assessed as part of the primary Requirement R4. No change made.	
Brazos Electric Cooperative	Same general comment in 4.4 and 4.5 about the requirement to maintain documentation on why certain events would produce less severe results.
Response: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the contingencies selected are already justified as those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results".	
American Electric Power	The cross-referencing between R4.1 and R4.4, and between R4.2 and R4.5, seems to add unnecessary complexity and could be eliminated by merging each of these pairs of sub-requirements. Under the event column of Table 1 of the proposed TPL standard, considering entries P3 and P6, the option to apply either SLG or 3-phase fault types should be retained to be consistent with the existing TPL standards, which permit either SLG or 3-phase faults (see existing Table 1, Category B and Category C3). If the SDT decides not to make the requested change, then the SDT should give recognition to the unique characteristics of 765 kV lines where permanent 3-phase faults are virtually non-existent. AEP's 765 kV transmission facilities have been successfully planned and operated with only a SLG fault criterion. Therefore, Table 1 Planning Events P3 and P6 should permit application of SLG faults.
Response: The SDT does not see any harm in having the cross referencing. No change made.	

Organization	Question 4 Comment
Table 1: Requirement R1.3.1 in TPL-002-0a states that simulations should "Be performed and evaluated only for those Category B Contingencies that would produce the more severe System results or impacts." The SDT believes that the intent of the existing TPL standards is to simulate the worst case whether three phase or single-line-to-ground. The new standard is clarifying that three-phase is required for single Contingency events. No change made. Note that AEP may request an entity variance from this part of the standard.	
ITC Holdings	Comments: In R2.5.1, a limitation is identified for stability studies that are used to support the annual assessment be less than five calendar years old. Should this reference be included in R4??
Response: R4: Because the five year limitation is stated in Requirement R2, part 2.5.1, there is no need to repeat it in Requirement R4. No change made.	
LADWP	R4.5 See coments on R3.4 and 3.5
Response: See response to comments for Requirement R3, parts 3.4 and 3.5.	
Platte River Power Authority	R4.3.2. Delete this requirement as it is covered under MOD-013-1, R1.2 for RRO Dynamics Data requirements. When the generator is modeled accordingly the generator's performance will be simulated and analyzed in the stability studies. R4.3.3. Delete this requirement as it is covered under MOD-013-1, R1.2 and R1.3 for RRO Dynamics Data requirements. When the generator is modeled accordingly the generator's performance will be simulated and analyzed in the stability studies.
Response: R4.3.2: The SDT has changed the wording of Requirement R4, part 4.3.2 for additional clarification. This does not require the modeling of generator relays although that is one method that could be used to meet the requirement. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.3.3: MOD-013 does not require the data to be used for an assessment of the Transmission System. Therefore, the requirement to simulate the operation of exciters and stabilizers is needed in this standard. No change made.	
MAPPCOR	R4.3.2 - Traditionally transmission planners have assumed that generators would ride through low voltages associated with Planning Events which is generally adequate for non-wind generators. If this standard is going to require its incorporation into the assessments, there should be an MOD standard developed requiring the generators to provide the necessary information prior to its inclusion as a requirement in this standard. R4.5 -Recommend that the requirement for Extreme Event testing be removed from this standard as there is no requirement to develop a Corrective Action Plan to address unacceptable consequences. Otherwise we recommend the following:-Extreme Event performance should be a consideration when developing Corrective Action Plans to address Planning Events-It should be clear that an evaluation does not require solution development for all Extreme Events-Change “an evaluation of possible actions”? to “where appropriate, reasonably practicable actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be considered.

Organization	Question 4 Comment
Response: R4.3.2: There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. Requirement R4, part 4.3.2 requires you to include in the assessment how you analyzed voltage ride-through capability. If complete information on the ride-through capability is not available, then you should document your assumptions regarding ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.5: The SDT considers extreme event testing to be an important part of the assessment and therefore will not delete it. The expectation for extreme event testing is that for major problems you will evaluate actions to reduce likelihood or mitigate consequences. The SDT believes the original words express this concept better than your suggested words. No change made.	
Orlando Utilities Commission	For Requirement 4.3.1 and 4.3.3 I suggest adding language similar to 3.3.2 and 3.3.3 establishing that “studies shall consider” rather then requiring every simulation precisely recreate this usually minor part of system performance. These devices generally do not respond except for a nearby event, and even then their response is rarely such that it would make the situation “worse”. The effect of these devices must be considered, but mandating that every simulation faithfully reproduce the response of every device is not only an efficient way to do this, it actually provides a counter incentive to going above and beyond the standard requirements. Any simulation used to meet this standard that failed to precisely reproduce the performance of this equipment would be a violation of this requirement (as currently written). As such there is no incentive for an entity to include anything but the absolute minimum number of simulations required to meet the standard, since each extra simulation represents an opportunity to miss this requirement. Good planning is based on running a broad range of events against a broad range of conditions and evaluating those responses against a set of performance criteria. This is encouraged by requiring that studies consider the response of equipment to these events rather then mandating their precise reproduction in simulation. Requirement 4.4 and 4.5 establish that only those events that would cause the most severe system impacts should be studied. This is an excellent requirement since it focuses the large resource requirement in performing these studies on the events that will provide the best information. Does the intent of the “More severe events” to establish actual study parameter extend between the planned events (R4.4) and extreme events (R4.5)? Or phrased another way, if an entity selects a proper range of extreme events and establishes that planning event performance requirements are met, could that be used as evidence that R4.4 is met as well, or would R4.4 require the same conditions be reproduced in their less severe configuration.
Response: R4.3.1: The SDT believes you should simulate the removal of System elements that Protection System and other controls would remove, not just consider it. No change made. R4.3.3 (now Part 4.3.4): The SDT has clarified that the devices to be included in the study which provide dynamic control are those that impact the study area. R4.4 and R4.5: You can always demonstrate that performance requirements are met by meeting them for a more severe Contingency. It is possible that you could demonstrate that performance requirements are met for planning events by performing extreme events (e.g., using a three-phase fault with stuck breaker Contingency can demonstrate that performance requirements for a single phase fault plus stuck breaker Contingency is met).	
American Transmission	We propose the following comments for R4:Add R4.3.3 text to include relay loadability in the R4 (Stability) requirements to

Organization	Question 4 Comment
Company	parallel R3.3.3 in the R3 (Steady State) requirement which would more clearly relate to the specific requirements in PRC-023. We suggest this text: "Incorporate relay loadability per PRC-023 and identify how relay loadability is analyzed in the dynamic simulation. In R4.3.4, we propose limiting the scope to automatic devices and adding the notion of "including but not limited to". We suggest R4.3.4 text of: "Simulate the expected automatic operation of existing and planned control devices including but not limited to generation exciter control and power system stabilizers, static VAR compensators, power flow controllers, and DC Transmission controllers. Add R4.3.5. The obligation to consider only planned System adjustments that are executable should be a Requirement, rather than performance note "e" in the Planning Events, Steady State & Stability section of Table 1. We suggest this text that matches R3.3.5: "Consider planned System adjustments, such as Transmission configuration changes and redispatch of generation, that are executable within the time duration of the applicable Facility Ratings.
Response: R4.3.3: The SDT agrees with the general idea and has added Requirement R4, part 4.3.3. However, Requirement R4, part 4.3.3 requires that you "Simulate the impact of transient swings on Protection System operation for Transmission lines and transformers" rather than creating a Stability requirement for relay loadability. This requirement is more applicable to Stability studies than a relay loadability requirement would be. Relay loadability is more of a steady state issue than a dynamic issue. **4.3.3** Simulate the impact of transient swings on Protection System operation for Transmission lines and transformers. R4.3.4: The SDT has made the suggested changes. **4.3.4** Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers. R4.3.5: Header note 'e' gives permission to use System adjustments under certain conditions. This is not a requirement and doesn't need to be included in Requirement R4. No change made.	
Idaho Power	R4.3.2 Generation protection system contain up to a dozen tripping functions functions. Is the intent to model all relay protection? The existing commercial programs do not have sufficient models or capacity to do that for all generators in the system.R4.5 ? Again I disagree with this requirement. It is the same as R3.5 and overly burdensome.
Response: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require extensive modeling of all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	

Organization	Question 4 Comment
Duke Energy	Revise M4 to include a reference to R6, since the allocation of responsibilities will directly affect the evidence which is to be provided.
Response: M4: The SDT disagrees. No change made.	
California ISO	As currently drafted, R4.3 is not a requirement. Without the statements in R4.3.1-R4.3.3, R4.3 is simply a phrase. Sub-Sub-Requirements R4.3.1 through R4.3.3 should be bullets under R4.3, with the language in R4.3 modified so that it becomes the requirement to conduct contingency analyses that address the three resulting bullets. R4.3.2 it is not clear what is required to be modeled. Typically a generator may have 10 or more protective relays. Is the intent to model all relay protection? The existing commercial programs do not have sufficient models or capacity to do that for all generators in the system. R4.5 We disagree with the requirement to explain why remaining Extreme Contingencies would produce less severe System results than the ones selected for study. The first part of the requirement requires identification of events that produce more severe System impacts. The reason the others were not selected is because they were less severe or non-credible. In any case, theoretically, there can always be a more severe Extreme Contingency than the one selected for study. For example, if the Extreme Contingency studied were simultaneous loss of 3 transmission lines with failure of redundant RAS, then simultaneous loss of 4 lines with failure of 2 sets of redundant RAS would be more severe. Listing all possible extreme events could result in a limitless list.
Response: R4.3: The SDT disagrees as these are mandatory elements of the Contingency analyses. Bullets are only used to identify the possible, but not all inclusive, elements of a menu. However, Requirement R4, part 4.3 has been modified to read more like a requirement as shown below. **4.3** Contingency analyses shall be performed and: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require modeling of all relay protection. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. R4.5: Several industry commenters have indicated that an explanation of "why the remaining Contingencies would produce less severe System performance" should be deleted since the Contingencies selected are those that produce more severe System performance. The SDT agrees and has deleted the requirement for an "explanation of why the remaining Contingencies would produce less severe System results". **4.5** Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list of those events to be evaluated for System performance in Requirement R4, part 4.2 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there are cascading outages caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.	

Organization	Question 4 Comment
Independent Electricity System Operator	. Same comments as in R3, above, except our proposed wording on R4 will read:R4. The Stability analyses of the Near-Term Planning Assessment as stipulated in R2.4.2 shall be performed as follows:. since there are no detailed requirements stipulated for Stability analysis portion for the Long-Term Planning Assessment. However, the main requirement contains a condition for performing the Contingency analyses listed in Table 1. First of all, there are no VSLs for failing to meet this condition. Secondly, this duplicates with some of the subrequirements, e.g. R4.4, R4.5. Suggest to remove this condition from the main requirement. If the main requirement is to be revised in a similar fashion as suggested for R3, then this will become a non-issue. 2. Similar to R3, we agree with the VRF, Time Horizon and Measure for R4. However, we do have the same difficulty with the VSL based on our comments on the convoluted nature of the requirement as indicated above, especially on the Moderate VSL for The Transmission Planner or Planning Coordinator did not base its studies on computer simulations using models utilizing data provided in Requirement R1.
Response: R4: The SDT does not see any need for Requirement R4 to reference back to Requirement R2, part 2.4. No change made. R4 VSL: (1) The VSL for Requirement R4 does cover failing to perform the Contingency analysis in Table 1. Depending on how many Contingency categories are not addressed, the violation could be moderate, high, or severe. No change made. R4 VSL: (2) Requirement R4 provides the general requirement to perform the Contingency analysis in Table 1. The parts like Requirement R4, part 4.4 provide more details on what must be run. There is no duplication. No change made. R4.5: The SDT believes that Requirement R4, part 4.5 is a necessary part. No change made. R4 VSL: The SDT disagrees with this idea. No change made.	
Kansas City Power & Light	R4.3 requires very labor intensive and detailed studies to be conducted; there are concerns about being able to accomplish the required studies within the 24 month implementation period; additionally, while there may be some reliability benefit to requiring these studies have the costs of this reliability increase been studied?; an alternative could be some sort of phased implementation (x% completed by 24months, etc.) R4.3.3 to what degree is generator relaying factored into the model/study?
Response: R4.3: The SDT believes that 24 months is sufficient to perform the additional studies. No change made. R4.3.3: Generator relaying is not a part of Requirement R4, part 4.3.3.	
ReliabilityFirst Corporation	R4.3.2 – Requires simulating generator voltage ride through capability. This may require modeling generator protection schemes to existing Dynamic models. This falls under which again falls under Section 1600 of NERC Rules of Procedure.
Response: R4.3.2: The intent of this requirement is to include in the assessment how voltage ride-through capability is analyzed in your studies. It does not require modeling of generator protection schemes. There is a reliability standard (PRC-024) under development which will require Generator Owners to provide information	

Organization	Question 4 Comment
about the low voltage ride through capability of their generators based on relay settings. If complete information on the ride-through capability is not available, then you should document your assumptions regarding voltage ride-through capability for the assessment. The SDT has changed the wording of Requirement R4, part 4.3.2 to clarify this. **4.3.2** Trip generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.	

5. Requirement R5 – Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: In response to industry comments, the SDT has deleted the word 'proxy' in favor of the terminology 'criteria or methodology' in Requirement R5 (now Requirement R6).

R6. Each Transmission Planner and Planning Coordinator shall define and document, within its Planning Assessment, any criteria or methodology used in its analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.

Organization	Question 5 Comment
Dominion - Electric Transmission Tucson Electric Power Company	Use of Proxies: There is no requirement that the Planning Coordinator (PC) must use the same proxies as the Transmission Planner (TP). Since differences in proxy assumptions may lead to different study results, R5 should be revised to require the PC and TP to coordinate the use of proxies.
Hydro-Québec TransEnergie (HQT)	There is no requirement that the Planning Coordinator must use the same proxies as the Transmission Planner. Differences in proxy assumptions may lead to different study results. R5 needs to be modified to require coordination of proxies between Planning Coordinators and Transmission Planners.
Response: Criteria or methodologies will be fleshed out in peer review. No change made.	
OPUC	MRO NSRS proposes specifying that the proxy documentation be included in the Planning Assessment and add the rationale for the proxy. MRO NSRS suggests this text: "Each Transmission Planner and Planning Coordinator shall document within the Planning Assessment any proxies used in the analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding. The documentation will consist of the definition of each proxy used and the rationale for the proxies.
Response: The SDT has revised the requirement language to provide greater clarity as to the intent. **R6.** Each Transmission Planner and Planning Coordinator shall define and document, within its Planning Assessment, any criteria or methodology used in its analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.	
Bonneville Power Administration	There is no requirement that the Planning Coordinator (PC) must use the same proxies as the Transmission Planner (TP). Since differences in proxy assumptions may lead to different study results, R5 should be revised to require the PC and TP to coordinate the use of proxies. M5 doesn't make any sense. Need to revise this Measure so that it fits the Requirement R5. Also need to revise the Data Retention discussion in Section 1.4 to align with R5. In the VSL associated with R5, we believe that failure to define and document one of the proxies should be a moderate VSL,

Organization	Question 5 Comment
	failure to define and document two proxies should me a high VSL, while failure to define and document three proxies should be a severe VSL. Otherwise failing to document only one proxy would result in a severe VSL.
Response: Criteria or methodologies will be fleshed out in peer review. The SDT has changed the language of Requirement R6 (formerly Requirement R5). **R6.** Each Transmission Planner and Planning Coordinator shall define and document, within its Planning Assessment, any criteria or methodology used in its analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding. The SDT does not agree and believes that the Measure appropriately addresses Requirement R6 (formerly Requirement R5). No change made. The SDT does not agree and believes that the Data Retention for this Requirement is in line with accepted Guidelines. No change made. The SDT appreciates your comment on the level of severity for this Requirement but still believes this is the appropriate level to apply. No change made.	
MRO MRO NERC Standards Review Subcommittee	We agree with the stated Requirement, Measure, VRF, Time-Horizon, Data Retention and VSL of requirement R5.
PacifiCorp	None - no concerns identified by the TWG
JEA	PEF does not presently have any concerns with R5.
Central Maine Power Company	We agree with the requirement, the VRF, Time Horizon, Measure and VSLs.
Response: Thank you for your response. However, due to other responses, some changes have been made. Please see the summary response.	
SRP	In R5 the term “proxy” needs to be defined. In addition, an example of a proxy should be given.
Gainesville Regional Utilities	R5:Guidelines for identifying proxies for unstable conditions would be helpful.
Progress Energy Florida, Inc.	The term proxy is unclear. Please provide an example or an explanation of proxy. If this is related to Note “i” in Table 1, it should be so stated. If it is related to assumptions or criteria, please state so.
Xcel Energy	Please clearify "Proxies"
Mississippi Delta Energy Agency	The term proxy is unclear. Please provide an example or an explanation of proxy. Perhaps a different term, such as metric, may better describe this requirement to more people.
Tenaska, Inc.	In R5, what is meant by the term “any proxies”? Please clarify. This comment also pertains to this terms use in the VSL as well.

Organization	Question 5 Comment
Manitoba Hydro	It is unclear as to what is meant by the term "proxy used in the analysis" used in this requirement. Is a "proxy" a "criteria"?
National Grid	Comments: The meaning of the word "proxies" in this context seems uncommon making the requirement unclear. Perhaps "proxies" should be replaced with "criteria" or "criteria or proxies".
Northern Indiana Public Service Company	What is a proxy as related to transmission planning? The drafting team should not introduce "non-standard" terms in a Standard document.
San Diego Gas and Electric Co	R5. For clarification, please list examples of "proxies" that might be used.
Minnesota Power	an example of proxy may be helpful, not all entities use proxies.
ISO New England, Inc. Western Area Power Administration American Electric Power Great River Energy New York Independent System Operator Modesto Irrigation District Louisiana Energy and Power Authority City Utilities of Springfield, MO Duke Energy New Brunswick System Operator MidAmerican Energy Company	The term proxy is unclear. Please provide an example or an explanation of proxy.
California ISO NorthWestern Corporation NorthWestern Energy (NWE) (NWMT)	The term "proxies" is somewhat confusing; recommend the use of "assumptions" if that is an acceptable substitute.
Independent Electricity System	On page 13 under Section R5, can the term "proxies" be defined and clarified, and examples given, in this context ?

Organization	Question 5 Comment
Operator Northeast Power Coordinating Council	
Kansas City Power & Light	5. Requirement R5 Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.Comments:A: An example should be added for proxy use.
IRC Standards Review Committee	We recommend using an alternate term for proxies such as criteria, guidelines, etc. to clarify what is meant.
Pepco Holdings, Inc. - Affiliates	We recommend that the word “proxies” be changed to “criteria”.
Transmission Planning	5. Requirement R5 Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.Comments:A: An example should be added for proxy use.
TVA System Planning	It is unclear as to what is meant by the term “proxy used in the analysis” used in this requirement. Does this mean Planning Coordinator established practices, thresholds or guidelines used to gauge when simulations suggest an event such as cascading outages occurs? If so the language should state: R5. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, when established practices, thresholds or guidelines identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.
United Illuminating	Please clarify how the term “Proxies” is used in this requirement.
PPL Energy Plus	Please define the term "proxies".
CPS Energy	Comments: It is unclear as to what is meant by the term “proxy used in the analysis” as it is used in this requirement. Does this mean Planning Coordinator established practices, thresholds, or guidelines used to gauge when simulations suggest an event such as cascading outages occurs? If so the language should state: R5. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, when established practices, thresholds or guidelines identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.
Response: The SDT agrees with this comment and has changed the Requirement language to provide clarity as to intent. **R6.** Each Transmission Planner and Planning Coordinator shall define and document, within its Planning Assessment, any criteria or methodology used in its analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.	
SERC Engineering Committee	In the VSL associated with R5, we believe that failure to define and document one of the proxies should be a moderate VSL,

Organization	Question 5 Comment
Reliability Review Subcommittee (RRS)	failure to define and document two proxies should me a high VSL, while failure to define and document three proxies should be a severe VSL. Otherwise failing to document only one proxy would result in a severe VSL. The word "proxies" in this context is confusing and subject to various interpretations. Recommend changing the word "proxies" to "criteria. There is no requirement that the Planning Coordinator (PC) must use the same proxies as the Transmission Planner (TP). Since differences in proxy assumptions may lead to different study results, R5 should be revised to require the PC and TP to coordinate the use of proxies.
Response: The SDT appreciates your comment on the level of severity for this Requirement but still believes this is the appropriate level to apply. No change made. The SDT agrees with this comment and has changed the Requirement language to provide clarity as to intent. **R6.** Each Transmission Planner and Planning Coordinator shall define and document, within its Planning Assessment, any criteria or methodology used in its analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding. The SDT does not see the need for a requirement to coordinate the use of proxies. No change made.	
FirstEnergy Corp	The determination of a failure to document a single proxy should not be categorized as "severe".
Response: The SDT appreciates your comment on the level of severity for this Requirement but still believes this is the appropriate level to apply. No change made.	
Southern Company	"Proxies" is not defined. We take "proxy" to mean a procedure used to model system response that is outside the capability of system modeling tools used in the analysis. For example, a powerflow model might not be able to model cascading events with built-in capabilities. As a proxy, the engineer would run follow-up studies that would mimic expected system response. Please define the term "proxy".
SMUD	It is unclear as to what is meant by the term "proxy used in the analysis" used in this requirement. Does this mean Planning Coordinator established practices, thresholds or guidelines used to gauge when simulations suggest an event such as cascading outages occurs? If so the language should state: R5. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, when established practices, thresholds or guidelines identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.
Platte River Power Authority	We propose specifying that the proxy documentation be included in the Planning Assessment and add the rationale for the proxy. We suggest this text: "Each Transmission Planner and Planning Coordinator shall document within the Planning Assessment any proxies used in the analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding. The documentation will consist of the definition of each proxy used and the rationale for the proxies.

Organization	Question 5 Comment
Turlock Irrigation District	Comments: It is unclear as to what is meant by the term “proxy used in the analysis” used in this requirement. Does this mean Planning Coordinator established practices, thresholds or guidelines used to gauge when simulations suggest an event such as cascading outages occurs? If so the language should state: R5. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, when established practices, thresholds or guidelines identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.
Response: The SDT agrees with this comment and has changed the Requirement language to provide clarity as to intent. **R6.** Each Transmission Planner and Planning Coordinator shall define and document, within its Planning Assessment, any criteria or methodology used in its analysis to identify System instability for conditions such as cascading outages, voltage instability, or uncontrolled islanding.	
Deseret Generation & Transmission	Please provide a definition of "cascading outages" since the FERC and NERC removed their approval of the definition. Or use the definition of "cascading" found in the NERC Glossary of Terms. This term is also used in R3.5, R4.5, and Table 1.a. without any definition provided. NOTE: On December 27,2007, the Federal Energy Regulatory Commission remanded the definition of” Cascading Outage” to NERC. On February 12, 2008, the NERC Board of Trustees withdrew its November 1, 2006 approval of that definition, without prejudice to the ongoing work of the FACstandards drafting team and the revised standards that are developed through the standardsdevelopment process. Therefore, the definition is no longer in effect. Please provide a definition of "voltage instability" since the NERC Glossary of Terms does not provide one. This term is also used in Table 1.a. without any definition provided. Please provide a definition of "uncontrolled islanding" since the NERC Glossary of Terms does not provide one. This term is also used in Table 1.a. without any definition provided.
Response: The SDT declines to provide definitions for the indicated terms.	
Puget Sound Energy, Inc.	Data Retention: The 5th bullet should refer to “proxies” instead of “studies”.
Response: The SDT disagrees with your statement as the studies will reveal the Proxies (now criteria or methodology) used in the Planning Assessment. No change made.	
E.ON U.S.	M5 doesn’t make any sense. Need to revise this Measure so that it fits the Requirement R5. Also need to revise the Data Retention discussion in Section 1.4 to align with R5. In the VSL associated with R5, we believe that failure to define and document the proxies should be a moderate VSL.
Response: The SDT does not agree and believes that the Measure appropriately addresses Requirement R6 (formerly Requirement R5). No change made. The SDT does not agree and believes that the Data Retention for this Requirement should be and is identical to the other Requirements. No change made. The SDT appreciates your comment on the level of severity for this Requirement but still believes this is the appropriate level to apply. No change made.	

Organization	Question 5 Comment
Entergy Services, Inc	Under R5, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R5 only says "Long-term Planning". By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: "Near-Term and Long-Term Transmission Planning".
ITC Holdings	Under R5, the Time Horizon of the TPL standards is intended for years one through 10; however, the Time Horizon shown in R5 only says "Long-term Planning". By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: "Near-Term and Long-Term Transmission Planning".

Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.

Operations Assessment — follow-up evaluations and reporting of real time operations.

Organization	Question 5 Comment
Idaho Power	M5 doesn't make any sense. Need to revise this Measure so that it fits the Requirement R5. Also need to revise the Data Retention discussion in Section 1.4 to align with R5.

Response: The SDT does not agree and believes that the Measure appropriately addresses Requirement R6 (formerly Requirement R5). No change made.

6. Requirement R6 – Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis required to meet the requirements of the TPL standard and to the Corrective Action Plan developed as part of the Planning Assessment. The intent of this requirement is to clarify that while the responsibilities for the TPL requirements are for both the Transmission Planner and Planning Coordinator, the individual tasks may be met through joint or shared analysis. Industry feedback indicates that it is important to minimize duplicative studies to the greatest extent possible. Coordinating and/or joint analysis does not alleviate the responsibility that all entities need to comply with the standard requirements. The SDT has made changes for clarity.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.

Organization	Question 6 Comment
Northeast Power Coordinating Council United Illuminating Northeast Utilities ISO New England, Inc. Central Maine Power Company	We do not feel that this requirement belongs in this standard and it should be deleted. The standard defines requirements for the assessment not who does what.
Response: The intent of this requirement is to clarify that TPL requirements can be meet through joint or shared analysis. Industry feedback indicates that it is important to minimize duplicative studies to the greatest extent possible. This requirement does not preclude any single entity from performing all the study work required to support an assessment. No change made.	
MRO NERC Standards Review Subcommittee	MRO NSRS is not clear if: 1) Each Transmission Planner is to meet all the requirements including doing all the studies and all Planning coordinators are to meet the requirements including doing all the studies.Or 2) If the Transmission Planner and Planning Coordinator are to work as a team to meet all the requirements including doing all the studies. Either one of them could do various parts of the required studies. For example, maybe the PC could do the stability part so all TP's would not necessarily have to buy that software if they did not need it for other planning purposes.In the first read of this standard, it appears that the intention was number 1, which sounds awfully duplicative. But then take a look at Requirement 6. R6. Each Transmission Planner and Planning Coordinator shall determine and identify individual and joint responsibilities for performing the required studies for the Planning Assessment. [Violation Risk Factor: Low] [Time Horizon: Long-term Planning]After reading R6, it appears that number 2 was intended. Perhaps R6 should be the very first requirement in the standard. The MRO NSRS requests that the NERC SDT clarify the responsibility of the requirements of this standard.

Organization	Question 6 Comment
Response: The requirement specifies that individual and joint responsibilities for performing the required studies be identified. Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis required to meet all the requirements of the TPL. **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.	
SERC Engineering Committee Reliability Review Subcommittee (RRS)	In absence of these agreements, it is assumed that both Transmission Planners and Planning Coordinators would be responsible for performing the studies. How do the Corrective Action Plans get resolved between these entities if there is no agreement on the study results??Requirements R1, R2, R3, R4 and R5 should all be revised to include a reference to R6 regarding the determination of individual and joint responsibilities for performing the required studies. In the VSL associated with R6, we believe that failure to determine and identify one responsibility should be a moderate VSL, failure to determine and identify two responsibilities should me a high VSL, while failure to determine and identify three responsibilities should be a severe VSL. Otherwise failing to document only one responsibility would result in a severe VSL.
Response: Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis required to meet all the requirements of the TPL and to the corrective action plan developed as part of the assessment. The proposed changes to the VSLs do not conform to Guideline 3 of the FERC VSL order. No change made to the VSL. **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.	
FirstEnergy Corp	We agree with the stated Requirement, Measure, VRF, Time-Horizon, Data Retention and VSL of requirement R6.
Progress Energy Florida, Inc.	PEF does not presently have any concerns with R6.
American Transmission Company	We agree with the revisions to R6.
Independent Electricity System Operator	We agree with the requirement, the VRF, Time Horizon, Measure and VSLs.
Response: Thank you for your response. However, please see changes indicated in the summary due to other industry comments.	
TVA System Planning	In the VSL associated with R6, we believe that failure to determine and identify one responsibility should be a moderate VSL, failure to determine and identify two responsibilities should me a high VSL, while failure to determine and identify three responsibilities should be a severe VSL. Otherwise failing to document only one responsibility would result in a severe VSL.
Response: The proposed changes to the VSL do not conform to Guideline 3 of the FERC VSL order. No change made	

Organization	Question 6 Comment
Florida Reliability Coordinating Council, Inc - Transmission Working Group	Please clarify that the phrase “individual and joint responsibilities” applies to entities (e.g., the TPs and PCs) and not specific individuals.R6 Please clarify if this requirement is intended for cases where a TP is not a PC and therefore is working “under” a PC? Or if this is intended to apply across neighboring PC’s?
FMPA	Please clarify that the phrase “individual and joint responsibilities” applies to entities (e.g., the TPs and PCs) and not specific individuals.
Response: Thank you for pointing out a potential for misinterpretation of the intent of the requirement. The SDT has modified the language. **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity’s individual and joint responsibilities for performing the required studies for the Planning Assessment.	
Xcel Energy	Why is this needed if both entities must comply with the standard?At a minimum the requirement should include language to state that the one party must provide to the other with enough notice to comply with a required study if there is a shift or assignment of a responsibility.
Ameren	In absence of these agreements, it is assumed that both Transmission Planners and Planning Coordinators would be responsible for performing the studies. It is not clear how the Corrective Action Plans get resolved between these entities if there is no agreement on the study results.
Duke Energy	Requirements R1, R2, R3, R4 and R5 should all be revised to include a reference to R6 regarding the determination of individual and joint responsibilities for performing the required studies.
Response: Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis to meet all the requirements of the TPL. This includes the corrective action plan developed as part of the assessment. Coordinating and/or joint analysis does not alleviate the responsibility that all entities need to comply with the standard requirements. **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity’s individual and joint responsibilities for performing the required studies for the Planning Assessment.	
Midwest ISO	A) Under R6, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R6 only says “Long-term Planning”. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: “Near-Term and Long-Term Transmission Planning”.
Minnesota Power	Under R6, the Time Horizon of the TPL standards is intended for years one through 10; however, the Time Horizon shown in R6 only says “Long-term Planning”. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10 and beyond. Suggestion to change the Time Horizon to read: “Near-Term and Long-Term Transmission Planning”.
Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time	

Organization	Question 6 Comment
frames. Time Horizons are a consideration when there is a violation of a requirement – the impact to the BES of violating a requirement with a long-term planning horizon is not expected to be as severe as the impact associated with violating a requirement with a real-time operations time horizon. No change made. **Mitigation Time Horizon** The time horizons available for mitigating a violation to a requirement include the following: • **Long-term Planning** — a planning horizon of one year or longer. • **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal. • **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time. • **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system. • **Operations Assessment** — follow-up evaluations and reporting of real time operations.	
Brazos Electric Cooperative	is there any other way to identify responsibilities between the parties than having an agreement? R6 seems to indicate an agreement of some sort must be in place. if that is the case then it could simply say an agreement must be in place.
Response: The requirement has been clarified in response to others' comments. The SDT did not want to imply that a separate agreement would be required for the purposes of the assessment. **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.	
ITC Holdings	Comments: Should this requirement state that ?The Transmission Planner in conjunction with their Planning Coordinator shall determine and identify individual and joint responsibilities for performing the required studies for the Planning Assessment.
Response: The SDT has modified the language**.** **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.	
LADWP	R6: Does this requirement requires authors of the planning assessment report should be identified? If so, can we use plain English like "The authors of the Planning Assessment report shall be identified". If not, please explain what this requirement is all about.
Kansas City Power & Light	Why is this needed if both entities must comply with the standard?At a minimum the requirement should include language to state that the one party must provide to the other with enough notice to comply with a required study if there is a shift or assignment of a responsibility.

Organization	Question 6 Comment
Response: Requirement R6 (now Requirement R7) is an overarching requirement that applies to the entire set of analysis required to meet all the requirements of the TPL and to the corrective action plan developed as part of the assessment. The intent of this requirement is to clarify TPL requirements can be met through joint or shared analysis. Industry feedback indicates that it is important to minimize duplicative studies to the greatest extent possible. Coordinating and/or joint analysis does not alleviate the responsibility that all entities need to comply with the standard requirements. **R7**. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.	
Orlando Utilities Commission	R6: Is this requirement intended for cases where the TP is not also their PC, or is this between adjacent PC's?
Response: The intent of this requirement is to clarify TPL requirements can be meet through joint or shared analysis. Industry feedback indicates that it is important to minimize duplicative studies to the greatest extent possible. The requirement has been clarified in response to others' comments. **R7**. Each Planning Coordinator, in conjunction with each of itsTransmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment.	

7. Requirement R7 – Please provide any specific comments on the requirement text, VRF, Time Horizon, measure associated with the requirement, data retention associated with the requirement, and/or the VSL associated with the requirement.

Summary Consideration: Many commenters feel that the reference to FERC Order 890 is inappropriate, but most do not argue against the importance of sharing Planning Assessment information. There was also concern about the meaning of the phrase "coordinating of analysis of these results", and what was specifically required. The SDT believes sharing of information, understanding the impact on/from neighboring areas, peer review/feedback, and wide area assessment are important to effective Transmission planning. As a result of the comments several revisions have been made to TPL-001-1.

Revisions to Requirement R3, part R3.4 and Requirement R4, part 4.4 will clarify the expectation that Transmission Planner's and Planning Coordinator's analyze Table 1 events outside their System for reliability impacts to understand neighboring System impacts. The revised TPL-001-1 Requirement R8 (formerly Requirement R7) will ensure appropriate information is exchanged between Transmission Planner's and Planning Coordinator's for sharing of information, review, and coordination of plans in conformance with Order 693, paragraph 1755 and 1756 expectations by requiring distribution of Planning Assessments to neighboring Transmission Planners and Planning Coordinators, as well as entities with a reliability-related need. The NERC Rules and Procedures and delegation agreements cover existing TPL-005-0 & TPL-006-0 assessment requirements for regional and inter-regional assessments allowing for retirement of these two standards. The aggregate effect of the above items will be an overlapping assessment of BES reliability from each Transmission Planner area up through each Interconnection.

R8 Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.

R8.1 If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8 Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient, date, and contents, or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and any functional entity who has indicated a reliability need and has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

R8 VSL	The responsible entity failed to distribute the results of its Planning Assessment to any one of its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.	N/A	The responsible entity failed to distribute the results of its Planning Assessment to its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.	The responsible entity failed to provide a documented response to a recipient of the Planning Assessment results who provided documented comments on the results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

Organization	Question 7 Comment
Northeast Power Coordinating Council United Illuminating Northeast Utilities ISO New England, Inc. National Grid Central Maine Power Company	This standard should not be reiterating FERC Order 890. We do not feel that this requirement belongs in this standard and it should be deleted.
SERC Engineering Committee Planning Standards Subcommittee	FERC Order 890:The reference to FERC Order 890 as it is currently written makes it seem like a suggestion to follow Order 890. If Order 890 explicitly describes this process then the sentence should read “as described in FERC Order 890. If not, this should not be mentioned at all.
Bonneville Power Administration PacifiCorp Deseret Generation & Transmission SRP Arizona Public Service Co Western Area Power Administration Pacific Gas and Electric Co, Puget Sound Energy, Inc. NV Energy Southern California Edison Company San Diego Gas and Electric Co California ISO Tucson Electric Power Company	We believe that references to FERC Orders should not be included in requirements of standards. This comment also applies to M7.

Organization	Question 7 Comment
NorthWestern Corporation NorthWestern Energy (NWE) (NWMT)	In R7 the references to FERC Orders should not be included in requirements of standards. This comment also applies to M7.
Response: The SDT agrees that the standard should not reference Order 890 and the reference has been deleted. **R8** Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results. **M8** Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient, date, and contents, or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and any functional entity who has indicated a reliability need and has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.	
MRO NERC Standards Review Subcommittee	MRO NSRS proposes expanding the scope of entities to consider, limit it to those entities that indicate a reliability need for coordination, and eliminate the direct reference to Order 890. MRO NSRS suggests this text: "Each Planning Coordinator shall establish a list of adjacent Planning Coordinators and any functional entity who has indicated a reliability need, distribute its Planning Assessment results to the listed entities and consider comments on the assumptions and results through an open and transparent peer review process.
Response: The scope of entities has been modified. Each Transmission Planner and Planning Coordinator shall distribute Planning Assessment results to adjacent Transmission Planners and Planning Coordinators, respectively; and to any functional entity that indicates a reliability-related need for the Planning Assessment results. An additional sub-requirement has been added to require that if a recipient of the Planning Assessment results provides documented comments on the results, the respective Transmission Planner or Planning Coordinator shall provide a documented response to that recipient within 90 calendar days of receipt of those comments. **R8.1** If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.	
SERC Engineering Committee Reliability Review Subcommittee (RRS)	The reference to FERC Order 890 as it is currently written makes it seem like a suggestion to follow Order 890. If Order 890 explicitly describes this process then the sentence should read "as described in FERC Order 890. If not, this should not be mentioned at all. " Requirement R7 describes that the Planning Coordinator is to share Planning Assessments with adjacent Planning Coordinators. Does this need to be expanded for the Transmission Planners to share their Planning Assessments with the Planning Coordinators?? In the VSL associated with R7, we believe that the PC failing to coordinate analysis should be a moderate VSL, the PC failing to distribute should be a high VSL, and failing to do both of these tasks should be a severe VSL.

Organization	Question 7 Comment

Response: The SDT agrees that the standard should not reference Order 890 and the reference has been deleted.

The scope of entities has been modified. Each Transmission Planner and Planning Coordinator shall distribute Planning Assessment results to adjacent Transmission Planners and Planning Coordinators, respectively; and to any functional entity that indicates a reliability-related need for the Planning Assessment.

The VSL has been modified to reflect the changes to the requirement. The requirement no longer requires a coordinated analysis. The failure to distribute the results is a High VSL. Failure to respond to comments is a Severe VSL.

R8 Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.

R8 VSL	The Transmission Planner or Planning Coordinator failed to distribute the results of its Planning Assessment to any one of its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.	N/A	The Transmission Planner or Planning Coordinator failed to distribute the results of its Planning Assessment to its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.	The Transmission Planner or Planning Coordinator failed to provide a documented response to a recipient of the Planning Assessment results who provided documented comments on the results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

Organization	Question 7 Comment
FirstEnergy Corp	We agree with the stated Requirement, Measure, VRF, Time-Horizon, Data Retention and VSL of requirement R7.
Progress Energy Florida, Inc.	PEF does not presently have any concerns with R7.

Response: Thank you for your response. However, please note the changes made to Requirement R7, Measure R7, and the Requirement R7 VSL (now Requirement R8) due to a majority of industry commenters indicating that some changes were needed.

Organization	Question 7 Comment
IRC Standards Review Committee	Is the PC expected to distribute the TP Planning Assessments as part of its coordination requirement?

Response: The term "coordinating analysis" has been deleted from the requirement and only distribution of assessments by the Transmission Planner and Planning Coordinator is required.

R8 Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.

Organization	Question 7 Comment
TVA System Planning	In the VSL associated with R7, we believe that the PC failing to coordinate analysis should be a moderate VSL, the PC failing to distribute should be a high VSL, and failing to do both of these tasks should be a severe VSL.

Response: The VSL has been modified to reflect the changes to the requirement. The requirement no longer requires a coordinated analysis. The failure to distribute the results is a High VSL. Failure to respond to comments is a Severe VSL.

R8 Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.

R8 VSL	The Transmission Planner or Planning Coordinator failed to distribute the results of its Planning Assessment to any one of its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.	N/A	The Transmission Planner or Planning Coordinator failed to distribute the results of its Planning Assessment to its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.	The Transmission Planner or Planning Coordinator failed to provide a documented response to a recipient of the Planning Assessment results who provided documented comments on the results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

Southern Company	We recommend the following wording for R7.Each Planning Coordinator shall coordinate the distribution of Planning Assessment results among adjacent Planning Coordinators and any functional entity who has indicated a reliability need. Each Planning Coordinator shall coordinate analysis of these results through an open and transparent peer review process such as described in FERC Order 890.

Response: The SDT agrees and, in addition, the scope of entities has been modified. Each Transmission Planner and Planning Coordinator shall distribute Planning Assessment results to adjacent Transmission Planners and Planning Coordinators, respectively; and to any functional entity that indicates a reliability-related need for the Planning Assessment results.

The VSL has been modified to reflect the changes to the requirement. The requirement no longer requires a coordinated analysis. The failure to distribute the results is a High VSL. Failure to respond to comments is a Severe VSL.

R8 Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.

R8 VSL	The responsible entity failed to distribute the results of its Planning Assessment to any one of	N/A	The responsible entity failed to distribute the results of its Planning Assessment to its adjacent Transmission	The responsible entity failed to provide a documented response to a recipient of the Planning Assessment

Organization	Question 7 Comment			
	its adjacent Transmission Planners and Planning Coordinators, respectively in accordance with Requirement R8.		Planners and Planning Coordinators, respectively in accordance with Requirement R8.	results who provided documented comments on the results within 90 calendar days of receipt of those comments in accordance with Requirement R8.
System Protection and Transmission Planning Department	The phrase "coordinating analysis of these results" seems to indicate potential second-guessing by other entities. We suggest "coordinating REVIEW of these results" may be clearer. The term "such as described in FERC Order 890" allows non-jurisdictional utilities to establish an appropriate process. This is good. However, we still have the same misgivings about the term "such as" used here.			
Manitoba Hydro	It is unclear as to what is meant by "coordinating analysis of these results"? Does this imply an obligation to conduct joint studies or just an obligation to distribute the assessment and respond to feedback? We suggest that the wording "such as described in FERC Order 890" be replaced with "such as may be required by a regulator in its PC/TP area". The SDT is posing several other questions for industry consideration not related to the specific requirement questions above.			
Response: The SDT agrees that the term "coordinating analysis" is unclear and has modified Requirement R7 (now Requirement R8) to only require distribution of planning assessments. The reference to Order 890 is no longer necessary. However, the SDT does believe it is appropriate to require a response if a recipient of the Planning Assessment results provides documented comments on the results. **R8** Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.				
PPL Energy Plus	Please continue to mention relevant FERC Orders (such as 890) in the standards since the FERC orders are the source of many of the planning standards. Planners need to acknowledge, respect, and design processes and systems around the FERC rulings.			
MidAmerican Energy Company	MidAmerican commends the SDT for its hard work on this standard. MidAmerican recommends changing R7 by changing "FERC Order 890" to "FERC Order No. 890".			
Response: The majority of commenters had an opposite opinion of referencing FERC Orders in NERC standards and the reference to Order 890 has been deleted.				
Florida Reliability Coordinating Council, Inc - Transmission Working Group	The requirement as written requires that the results of the assessment are shared on a post assessment basis between entities in a manner similar to the Attachment K process. Please clarify whether:-Is this intended to be the end results? Or does this require the inviting of entities in at the very beginning and facilitating their participation throughout the process? -Is it intended that the process described in order 890 become essentially a NERC Standard that every sentence must be met in the most literal of sense? Or is this referencing the order as a general guideline on what should be expected but not as a literal			

<table>
<tr><th>Organization</th><th>Question 7 Comment</th></tr>
<tr><td></td><td>checkmark of the process? Consider adding a footnote or other clarifications that failure of others to participate in the process is not a non compliance by the entity inviting them to the process. Otherwise non-responsiveness of a neighboring PC who may not have reliability need to participate and whose participation is beyond the control of the PC that initiated the process could trigger non-compliance.</td></tr>
<tr><td>Entergy Services, Inc</td><td>This requirement is addressed through FERC Order No. 890 (9 principles of transmission planning).</td></tr>
<tr><td>Platte River Power Authority</td><td>R7. Delete this requirement as it is the responsibility of the Transmission Provider under FERC Order 890.</td></tr>
<tr><td>American Transmission Company</td><td>We propose expanding the scope of entities to consider, limit it to those entities that indicate a reliability need for coordination, and eliminate the direct reference to FERC Order 890 and peer review. We suggest this text: “Each Planning Coordinator shall establish a list of adjacent Planning Coordinators and any functional entity who has indicated a reliability need, and distribute its Planning Assessment results to the listed entities and consider comments on the assumptions and results.</td></tr>
<tr><td colspan="2">Response: The reference to Order 890 created confusion regarding process requirements and the reference has been deleted. The standard now requires each Transmission Planner and Planning Coordinator to distribute Planning Assessment results to adjacent Transmission Planners and Planning Coordinators, respectively; and to any functional entity that indicates a reliability-related need for the Planning Assessment results. In addition, if a recipient of the Planning Assessment results provides documented comments on the results, the respective Transmission Planner or Planning Coordinator shall provide a documented response to that recipient within 90 calendar days of receipt of those comments. This simplifies the process while achieving appropriate involvement of affected entities.

R8 Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.

R8.1 If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.</td></tr>
<tr><td>SMUD</td><td>Requirement R7 should end after the words '....who has indicated a reliability need'. R7:The requirement should not invoke another document for compliance. The words, ", coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890', should be deleted. This comment also applies to M7.</td></tr>
<tr><td colspan="2">Response: The reference to Order 890 created confusion regarding process requirements and the reference has been deleted. <tr><td>Midwest ISO</td><td>A) Under R7, the Time Horizon of the TPL standards is intended for years one through 10; However the Time Horizon shown in R7 only says “Long-term Planning”. By definition of Long-Term Transmission Planning Horizon this covers years 6 through 10</td></tr>
</table>

Organization	Question 7 Comment
	and beyond. Suggestion to change the Time Horizon to read: "Near-Term and Long-Term Transmission Planning". B) The coordination of analysis of results through an open and transparent process is already a FERC requirement thus producing a double jeopardy for those entities that fall under the jurisdiction of FERC Order 890. We recommend striking the following language in the last sentence: ...coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890. C) Under R7 only the Planning Coordinator is required to coordinate the distribution of Planning Assessment results among adjacent PCs and any functional entity who has indicated a reliability need, coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890. Should the TP be added to this requirement? We propose the suggested language change: Each Transmission Planner and Planning Coordinator shall coordinate the distribution of Planning Assessment results among adjacent Transmission Planners and Planning Coordinators, respectfully, and to any functional entity who has indicated a reliability need, coordinating analysis of these results through an open and transparent peer review process such as described in FERC Order 890. D) Based on the comments above in (B) and (C), our suggested requirement language is as follows: Each Transmission Planner and Planning Coordinator shall coordinate analysis in support of assessments in accordance with applicable regulatory requirements. Each Planning Coordinator shall distribute its completed planning assessment results among adjacent Planning Coordinators and any functional entity who indicated in writing a reliability related need.

Response: The *Time Horizon* term at the end of the requirement deals with mitigation time periods (as shown below) and is not connected to the assessment time frames. No change made.

Mitigation Time Horizon

The time horizons available for mitigating a violation to a requirement include the following:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

The reference to "coordinating analysis" and Order 890 created confusion regarding process requirements and the requirement has been modified. The standard now requires each Transmission Planner and Planning Coordinator to distribute Planning Assessment results to adjacent Transmission Planners and Planning Coordinators, respectively; and to any functional entity that indicates a reliability-related need for the Planning Assessment results. In addition, if a recipient of the Planning Assessment results provides documented comments on the results, the respective Transmission Planner or Planning Coordinator shall provide a documented response to that recipient within 90 calendar days of receipt of those comments. This simplifies the process while achieving appropriate involvement of affected entities.

</td></tr>
<tr><td>PJM</td><td>

R7 needs to be broken into two parts. First establish the list of entities that need to get the assessment results.

Second would be to coordinate the results as mentioned. Are the results mentioned in R7 different from the Planning Assessment?
