For each interconnection, the distribution of the interconnection frequency fails the normality test (both the chi-square goodness-of-fit and the Kolmogorov-Smirnov goodness-of-fit) at any standard significance level. The combined datasets for the interconnection frequency consist of very large numbers of observations. For such large samples, the empirical distribution can be considered as a very good approximation of the actual distribution of the frequency, and was judged a better predictor than use of standards deviation for predicting the interconnection starting frequencies for an event. The rate of convergence in the Glivenko-Cantelli theorem is $n^{(-1/2)}$, where n is the sample size. Therefore, quantiles of the empirical distribution function can be used directly to calculate intervals where values of frequency belong with any pre-determined probability.

Only resource losses (frequency drops) are examined for IFRO calculations, so the focus is on the one-sided lower tail of the distribution for frequencies that fall outside the upper 95% interval of the overall distribution. Therefore, the starting frequency that should be used for the calculation of the IFROs is the 10% quantile frequency value, which represents a 95% confidence in the prediction for that single tail.

Those starting frequencies encompass all variations in frequency, including changes to the target frequency during time error correction. That eliminates the need to expressly evaluate TEC as a variable in the IFRO calculation.

Recommendation – The starting frequency for the calculation of IFROs should be frequency of the 5% of lower tail of samples from the statistical analysis, representing a 95% confidence that frequencies will be at or above that value at the start of any frequency event.

Figures 30–33 show the interconnection histograms broken into 1-mHz "bins." A complete set of graphs for the four interconnections is located in Appendix D of this report.

Figure 30: Eastern Interconnection 2009–2011 Frequency Histogram

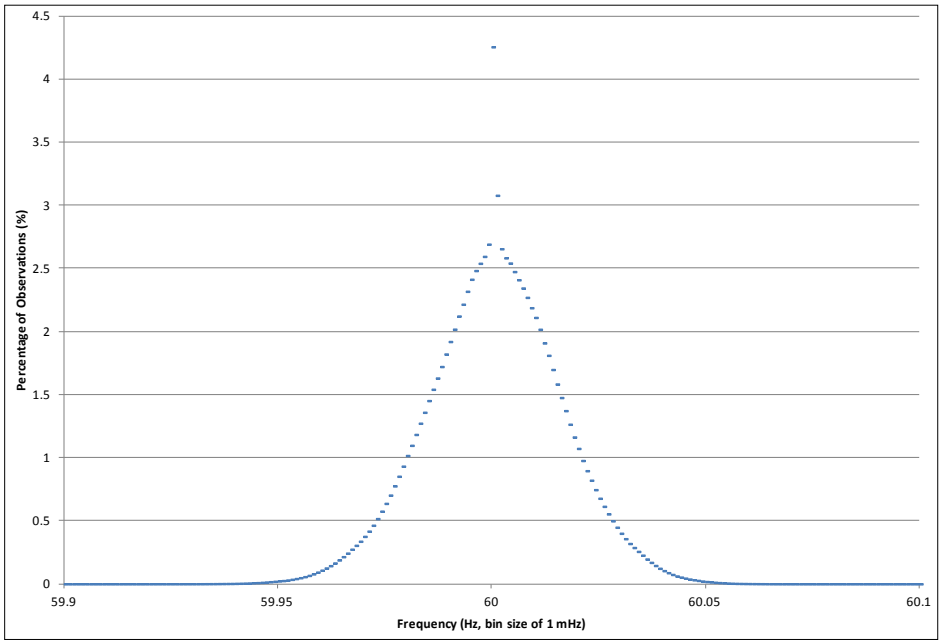

Figure 31: Western Interconnection 2009–2011 Frequency Histogram

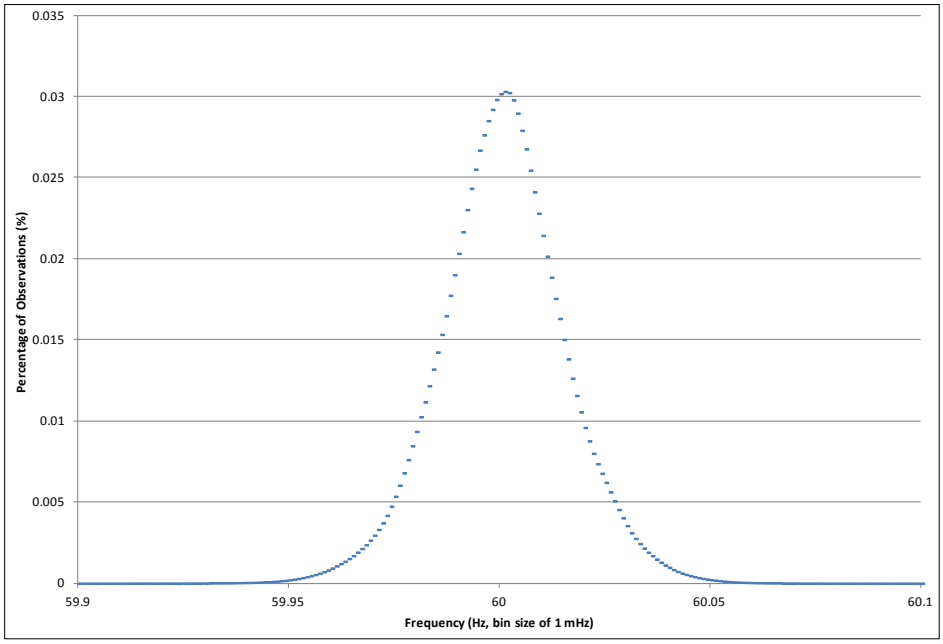

Figure 32: ERCOT Interconnection 2009–2011 Frequency Histogram

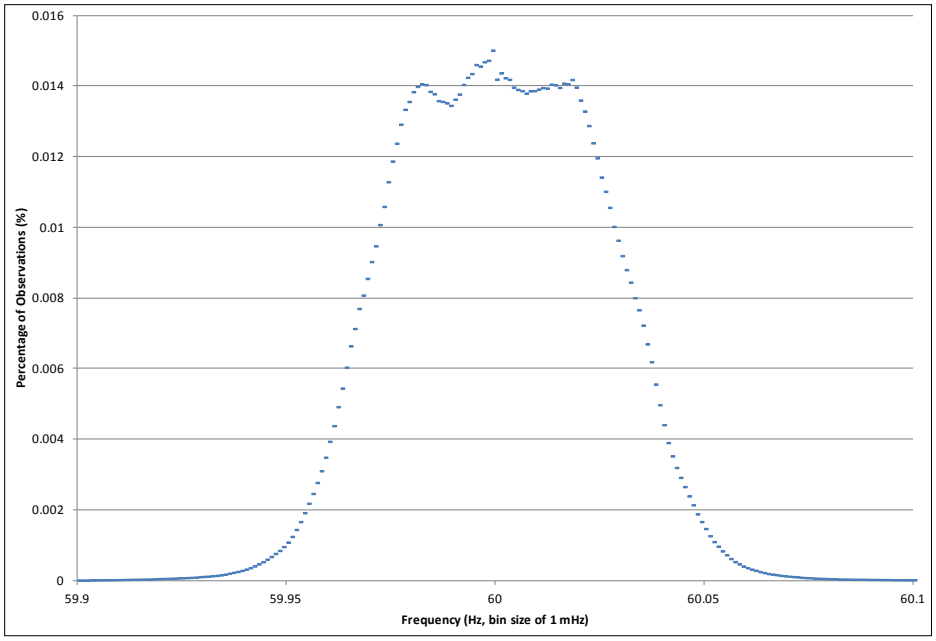
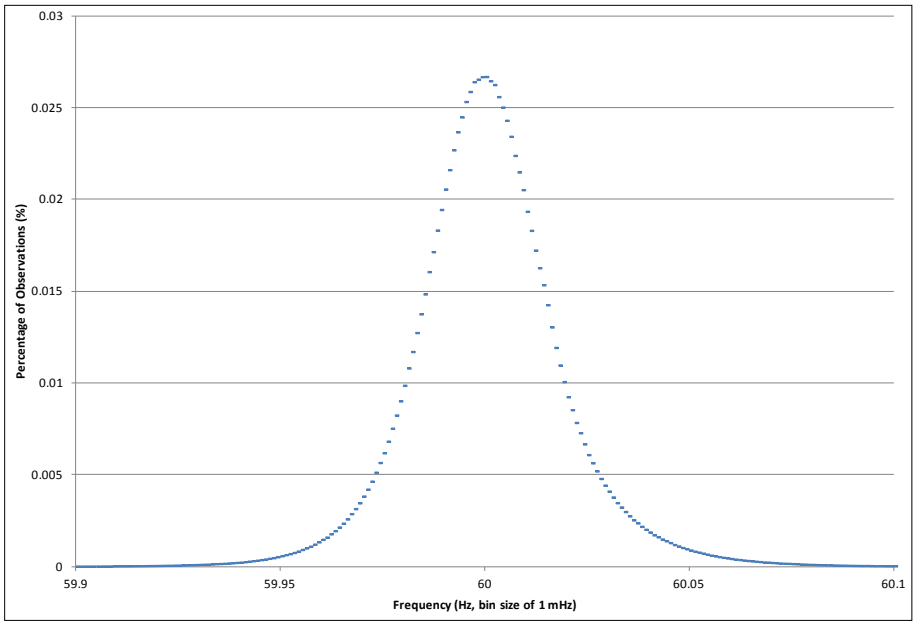


Note that the ERCOT frequency histogram displays the influence of the "flat-top" f profile that was common to that interconnection prior to 2008. That phenomenon was caused by a standardized ±36 mHz deadband with a step-function implementation. Additional discussion on that topic is in the ERCOT Experience section of this report.

Figure 33: Québec Interconnection 2010–2011 Frequency Histogram



Point C Analysis – One-second versus Sub-second Data

Additional statistical analysis was performed for the differences between Point C and Value B calculated as a ratio of Point C to Value B using 1-second data for events from December 2010 through May 2012. Although the 1-second data sample is robust, it does not necessarily ensure the nadir of the event was accurately captured. To do so requires sub-second measurements that can only be provided by PMUs or FDRs. Therefore, a "CC" adjustment component (CC_{ADJ}) for the IFRO calculation was designed to account for the differences observed between the 1-second Point C and high-speed Point C measurements.

Table 4: Analysis of One-second and Sub-second Data for Point C (CC_{ADJ})

Interconnection	Number of Samples	Mean	Standard Deviation	CC_{ADJ} (95% Quantile)
Eastern	30	0.0006	0.0038	0.0068
Western	17	0.0012	0.0019	0.0044
ERCOT	58	0.0021	0.0061	0.0121
Québec[33]	0	N/A	N/A	N/A

This adjustment should be made to the allowable frequency deviation value before it is adjusted for the ratio of Point C to Value B. Note: No sub-second data was available for the Québec Interconnection.

Recommendation – The allowable frequency deviation (starting frequency minus the highest UFLS step) should be reduced by the CC_{ADJ} to account for differences between the 1-second and sub-second data for Point C as listed in table B-C9.

Adjustment for Differences between Value B and Point C

All of the calculations of the IFRO are based on protecting from instantaneous or time-delayed tripping of the highest step of UFLS, either for the initial nadir (Point C), or for any lower frequency that might occur during the frequency event. The frequency variance analysis in the previous section of this report is based on 1-second data from 2007 through 2011 (except Québec 2010 and 2011 only).

As a practical matter, the ability to measure the tie line and loads for the Balancing Authorities is limited to system control and data acquisition (SCADA) scan-rate data of 1–6 seconds. Therefore, the ability to measure frequency response of the Balancing Authorities is still limited by the SCADA scan rates available to calculate Point B.

[33] Sub-second data from Québec was not available.

Candidate events from the ALR1-12 Interconnection Frequency Response selection process (Appendix E) for frequency response analysis were used to analyze the relationship between Value B and Point C for the significant frequency disturbances from December 2010 through May 2012. This sample set was selected because data was available for the analysis on a consistent basis. This resulted in the number of events shown in table 5.

Analysis Method

When evaluating some physical systems, the nature of the system and the data resulting from measurements derived from that system do not fit the standard linear regression methods that allow for both a slope and an intercept for the regression line. In those cases, it is better to use a linear regression technique that represents the system correctly.

The Interconnection Frequency Response Obligation is a minimum performance level that must be met by the Balancing Authorities in an interconnection. Such response is expected to come from the frequency response in MWs of the Balancing Authorities to a change in frequency. As such, if there is no change in frequency there should be no change in MWs resulting from frequency response.

This response is also related to the function of the frequency bias setting in the ACE equation of the Balancing Authorities for longer term. The ACE equation looks at the difference between scheduled frequency and actual frequency times the frequency bias setting to estimate the amount of MWs that are being provided by load and generation within the Balancing Authority. If the actual frequency is equal to the scheduled frequency, the frequency bias component of ACE must be zero.

Since the IFRO is ultimately a projection of how the interconnection is expected to respond to changes in frequency related to a change in MW (resource loss or load loss), there should be no expectation of frequency response without an attendant change in MW. It is this relationship that indicates the appropriateness of the use of regression with a forced fit through zero.

Evaluation of data to determine C-to-B ratio:

The evaluation of data to determine C-to-B ratio to account for the differences between arrested frequency response (to the nadir, Point C) and settled frequency response (Value B) is also based on a physical representation of the electrical system. Evaluation of this system requires investigation of the meaning of an intercept. The C-to-B ratio is defined as the difference between the pre-disturbance frequency and the frequency at the maximum deviation in post-disturbance frequency, divided by the difference between the pre-disturbance frequency and the settled post-disturbance frequency.

A stable physical system requires the ratio to be positive; a negative ratio indicates frequency instability or recovery of frequency greater than the initial deviation.

Table 5: Analysis of Value B and Point C (CBR)				
Interconnection	Number of Samples	Mean	Standard Deviation	CB_R (95% Quantile)
Eastern	41	0.964	0.0149	1.0 (0.989)[34]
Western	30	1.570	0.0326	1.625
ERCOT	88	1.322	0.0333	1.377
Québec[35]				1.550

This statistical analysis was completed using 1-second averaged data that does not accurately capture Point C and is better measured by high-speed metering (PMUs or FDRs). Therefore, a separate correction must be used to account for the differences between the Point C in the 1-second data and the Point C values measured with sub-second measurements from the FNet FDRs.

The CB_R value for the Eastern Interconnection indicates that the Value B is generally below the Point C value. Therefore, there is no adjustment necessary for that interconnection.

The Québec Interconnection's resources are predominantly hydraulic and are operated to optimize efficiency, typically at about 85% of rated output. Consequently, most generators have about 15% headroom to supply primary frequency response. This results in a robust response to most frequency events, exhibited by high rebound rates between Point C and the calculated B Value. For the 26 frequency events in their event sample, Québec's CB_R value would be 3.613, or two to three times as high as the CB_R value of other interconnections. Using the same calculation method for CB_R would effectively penalize Québec for their outstanding rebound performance and make their IFRO artificially high. Therefore, the method for calculating the Québec CB_R was modified.

Québec operates with an operating mandate for frequency responsive reserves to protect from tripping their 58.5 Hz (300 ms trip time) first step UFLS for their largest hazard at all times, effectively protecting against tripping for Point C frequency excursions. They also protect against tripping a UFLS step set at 59.0 Hz that has a 20-second time delay, which protects them for Value B low frequency and any withdrawals. This results in a Point C to Value B ratio of 1.5. To account for the confidence interval, 0.05 is then added, making the CB_R = 1.550.

Adjustment for Primary Frequency Response Withdrawal

At times, the nadir for a frequency event occurs after Point C—defined in BAL-003-1 as occurring in the T+0 to T+12 second period, during the Value B averaging period (T+20 through T+52 seconds), or later. For purposes of this report, that later occurring nadir is termed Point

[34] CB_R value limited to 1.0 because values lower than that indicate the Value B is lower than Point C and does not need to be adjusted. The calculated value is 0.989.

[35] Based on Québec UFLS design between their 58.5 Hz UFLS with 300 millisecond operating time (responsive to Point C)and 59.0 Hz UFLS step with a 20 second delay (responsive to Value B or beyond).

C'. This lower nadir is symptomatic of primary frequency response withdrawal, or squelching, by unit or plant-level outer-loop control systems. Withdrawal is most prevalent in the Eastern Interconnection, as described earlier.

As described in the Withdrawal of Primary Frequency Response section of this report, frequency response withdrawal can become important depending on the type and characteristics of the generators in the resource dispatch, especially during light load periods. Therefore, an additional adjustment to the maximum allowable delta frequency for calculating the IFROs was statistically developed. This adjustment should be used whenever withdrawal is a prevalent feature of frequency events. Initially, it is only being applied to the Eastern Interconnection.

Table 6 shows the statistical results of the analysis based on the 34 frequency response events in the Eastern Interconnection. Note that the expected timeframe for the C' nadir to occur is about 82 seconds after the start of the event.

Table 6: Statistical Analysis of the Adjustment for C' Nadir (BC'_{ADJ})

Value	Number of Samples	Mean	Standard Deviation	BC'_{ADJ} (95% Quantile)
Delta Frequency from Value B to Point C' Nadir	34	4.0 mHz	8.2 mHz	17.5 mHz
Seconds from T+0 to C' Nadir	34	38.9 s	26.3 s	82.1 s

This BC'_{ADJ} should be applied to the allowable delta frequency after the differences from Value B to Point C are adjusted. The values driving this adjustment should also be carefully monitored and the adjustment recalculated during the annual review of IFRO calculations.

Variables in Determination of Interconnection Frequency Response Obligation from Criteria

To make a determination of the appropriate Resource Contingency Protection Criteria to protect for a certain kind of event, the MW target value needs to be translated into an Interconnection Frequency Response Obligation (IFRO) for an appropriate comparison. A number of other variables must be taken into consideration.

Low Frequency Limit

The low frequency limit to be used for the IFRO calculations should be the highest setpoint in the interconnection for regionally approved UFLS systems.

Recommendation – Based on the tenet that UFLS should not trip for a frequency event throughout the interconnection, the recommended UFLS first-step limitations for IFRO calculations listed in table 7 should be used.

Table 7: Low-Frequency Limits (Hz)	
Interconnection	Highest UFLS Trip Frequency
Eastern	59.5[36]
Western	59.5
ERCOT	59.3
Québec	58.5

The highest UFLS setpoint in the Eastern Interconnection is 59.7 Hz in FRCC, while the prevalent highest setpoint in the rest of that interconnection is 59.5 Hz. The FRCC 59.7 Hz first UFLS step is based on internal stability concerns and preventing the Florida peninsula from separation from the rest of the interconnection. The FRCC concluded that the IFRO starting point of 59.5 Hz for the Eastern Interconnection is acceptable in that it imposes no greater risk of UFLS operation for an interconnection resource loss event than for an internal FRCC event.

Protection against tripping the highest step of UFLS does not ensure that generation that has frequency-sensitive protection or turbine control systems will not trip. Severe system conditions might drive the frequency to levels that may present protection and control systems with a combination of conditions that may cause the generation to trip, such as severe rate of change in voltage or frequency, which might actuate volts per hertz relays. Similarly, some combustion turbines may not be able to sustain operation at frequencies below 59.5 Hz. Recent laboratory testing by Southern California Edison of inverters used on residential and commercial scale photovoltaic (PV) systems revealed a propensity to trip at about 59.4 Hz, which is 200 mHz above the expected 59.2 Hz prescribed in IEEE Standard 1547 for distribution-connected PV rating ≤ 30 kW (57.0 Hz for larger installations). This could become problematic in areas of high penetration of photovoltaic resources.

Credit for Load Resources (CLR)

The ERCOT Interconnection depends on contractually interruptible demand that automatically trips at 59.7 Hz to help arrest frequency declines. A 1,400 MW Load Resource (formerly Load acting as a Resource – LaaR) credit is included against the Resource Contingency for the ERCOT Interconnection. Similarly, there is a remedial action scheme (RAS) in WECC that trips 300 MW of load for the loss of two Palo Verde generating units.

For the Western Interconnection, if the larger 3,200 MW resource loss activates the RAS and trips the Pacific DC Intertie (PDCI), the 300 MW credit for Load Resources associated with the loss of the two Palo Verde units does not apply.

[36] The highest UFLS setpoint in the Eastern Interconnection is 59.7 Hz in FRCC, based on internal stability concerns. The FRCC concluded that the IFRO starting frequency of the prevalent 59.5 Hz for the Eastern Interconnection is acceptable in that it imposes no greater risk of UFLS operation in FRCC for an external resource loss event than for an internal FRCC event.

For both interconnections, credit for load resources is handled in the calculation of the IFRO as a reduction to the loss of resources, when appropriate.

Interconnection Resource Contingency Protection Criteria

Selection of discrete event protection criteria for each interconnection must be done before the IFRO can be calculated. The protection criteria selected should ensure that Point C would not encroach on the first step UFLS. However, the criteria may need to be different from one interconnection to the other due to the differences in size and design characteristics.

The following potential interconnection event criteria were considered:

- largest N-2 loss-of-resource event,
- largest total generating plant with common voltage switchyard, and
- largest loss-of-resource event in the interconnection in the last 10 years.

Largest N-2 Event

For this approach, each interconnection will have a target Resource Contingency Protection Criteria based on the largest N-2 loss-of-resource event. This should not be confused with a Category C, N-2 event prescribed in the NERC TPL standards; it is intended to reflect a simultaneous loss of the resources without time for system adjustments. As such, these events would be considered Category D events in the current standards.

Table 8: Largest N-2 Event

Interconnection	Basis	MW
Eastern	Nelson DC Bi-poles 1 & 2	3,854[37]
Western	Two Palo Verde Units	2,740[38]
ERCOT	Two South Texas Project Units	2,750[39]

For both the ERCOT and Western Interconnections, that would be the loss of the two largest generating units in the interconnection. However, for the Eastern Interconnection, the largest N-2 loss-of-resource event would be the loss of the two Nelson dc bi-pole converters.

[37] Nelson Bi-poles 1 and 2 are rated 1,854 MW and 2,000 MW, respectively.

[38] Net winter ratings per Form EIA-860 reporting.

[39] Net rating from ERCOT Resource Asset Registration Form (RARF).

Largest Total Plant with Common Voltage Switchyard

Another approach is to examine the largest complete generating plant outage in each of the interconnections, limiting this classification to those generators with a common voltage switchyard. The reasoning for considering such a protection criteria is that despite popular belief, complete plant outages can and do happen on a regular basis; 15 complete plant outages occurred in North America in the 12 months from July 1, 2010 through June 30, 2011.

Table 9: Largest Total Plant with Common Voltage Switchyard		
Interconnection	Basis	MW
Eastern	Darlington Units 1-4	3,524[40]
Western	3 Palo Verde Units	3,575[41]
ERCOT	2 South Texas Project Units	2,750[42]

Note that in the Western Interconnection, multi-plant generation tripping by the operation of the Pacific Northwest remedial action scheme (RAS) results in resource loss of 3,200 MW. That issue is further discussed in the Special IFRO Considerations section of this report.

Largest Resource Event in Last 10 Years

A third approach is to examine the largest complete resource loss event in the interconnection over the last 10 years. Although this method yields a reasonable value for the Eastern Interconnection, the values for the other two interconnections would likely not be sustainable without activating some UFLS. It also results in a larger resource contingency for the Western Interconnection than for the Eastern Interconnection. These single events were not approached in magnitude by any other events in the 10-year period.

Table 10: Largest Resource Contingency Event in Last 10 Years		
Interconnection	Basis	MW
Eastern	August 4, 2007 Disturbance[43]	4,500
Western	June 14, 2004 Disturbance[44]	5,000
ERCOT	May 15, 2003 Disturbance[45]	3,400

[40] Net winter ratings from the NERC Electricity Supply and Demand.

[41] Net winter ratings per Form EIA-860 reporting.

[42] Net rating from ERCOT Resource Asset Registration Form (RARF).

[43] The August 4, 2007 frequency excursion was a complex, multi-faceted event involving nine generators across three states. Of those nine generators, seven tripped because of turbine control actions, and the others tripped on instability. This was not an N-1 event.

[44] The June 14, 2004 disturbance was a complex series of events thattripped ten generators across the western Interconnection as the result of a protracted fault. This was not an N-1 event.

Recommended Resource Contingency Protection Criteria

Because the philosophy is for the criteria to protect against the largest frequency excursion the interconnection can withstand, the contingency criteria may vary significantly between the interconnections. For example, because of its sheer size and generating capacity, the Eastern Interconnection can withstand a greater loss of resources.

Therefore, a blending of Resource Contingency Protection Criteria is recommended (table 4) for the determination of IFROs.

Table 11: Recommended Resource Contingency Protection Criteria

Interconnection	Resource Contingency	Basis	MW
Eastern	Largest Resource Event in Last 10 Years	August 4, 2007 Disturbance	4,500
Western	Largest N-2 Event	2 Palo Verde Units	2,740[46]
ERCOT	Largest N-2 Event	2 South Texas Project Units	2,750[47]

Although the size of a resource contingency that can be sustained by an interconnection should be tested through dynamic simulations, that test can currently be done only for the Western and ERCOT Interconnections.

Recommendation – Dynamic simulation testing of the Western and ERCOT Resource Contingency Protection Criteria should be conducted as soon as possible.

Recommendation – Dynamic simulation testing of the Eastern Interconnection Resource Contingency Protection Criteria should be conducted when the dynamic simulation models of the interconnection are capable of performing the analysis.

[45] The May 15, 2003 disturbance was a complex series of events that tripped six generators due to a protracted fault. This was not an N-1 event.

[46] Net winter ratings per Form EIA-860 reporting.

[47] Net rating from ERCOT Resource Asset Registration Form (RARF).

Comparison of Alternative IFRO Calculations

Each of the proposed resource loss criteria alternatives were compared through development of the corresponding IFROs. The following tables show the calculation of an IFRO for each alternative for the Eastern, Western, and ERCOT Interconnections. The criterion for the Québec Interconnection was kept constant throughout.

IFRO Formulae

The following are the formulae that comprise the calculation of the IFROs.

Where:

- DF_{Base} is the base delta frequency.
- F_{Start} is the starting frequency determined by the statistical analysis.
- UFLS is the highest UFLS trip setpoint for the interconnection.
- CC_{ADJ} is the adjustment for the differences between 1-second and sub-second Point C observations for frequency events. A positive value indicates that the sub-second C data is lower than the 1-second data.
- DF_{CC} is the delta frequency adjusted for the differences between 1-second and sub-second Point C observations for frequency events.
- CB_R is the statistically determined ratio of the Point C to Value B.
- DF_{CBR} is the delta frequency adjusted for the ratio of the Point C to Value B.
- BC'_{ADJ} is the statistically determined adjustment for the event nadir occurring below the Value B (Eastern Interconnection only) during primary frequency response withdrawal.
- MDF is the maximum allowable delta frequency.
- RLPC is the resource loss protection criteria.
- CLR is the credit for load resources.

- ARLPC is the adjusted resource loss protection criteria adjusted for the credit for load resources.
- IFRO is the interconnection frequency response obligation.

Determination of Maximum Delta Frequencies

Because of the limitation of measurement of the Balancing Authority-level frequency response performance using Value B, the Interconnection Frequency Obligations must be calculated in "Value B space." Protection from tripping UFLS for the interconnections based on Point C (the nadir defined as occurring between T=0 and T+12 seconds in BAL-003-1), Value B (defined as occurring from T+20 seconds to T+52 seconds), or any nadir occurring after point C, within Value B, or after T+52 seconds must be reflected in the maximum allowable delta frequency for IFRO calculations expressed as a Value B.

Table 12: Determination of Maximum Delta Frequencies

	Eastern	Western	ERCOT	Québec	Units
Starting Frequency	59.974	59.976	59.963	59.972	Hz
Minimum Frequency Limit	59.500[48]	59.500	59.300	58.500	Hz
Base Delta Frequency	0.474	0.476	0.663	1.472	Hz
CC_{ADJ}	0.007	0.004	0.012	N/A	Hz
Delta Frequency (DF_{CC})	0.467	0.472	0.651	1.472	Hz
CB_R	1.000[49]	1.625	1.377	1.550[50]	Hz
Delta Frequency (DF_{CBR})[51]	0.467	0.291	0.473	0.949	Hz
BC'_{ADJ}	.018	N/A	N/A	N/A	Hz
Max. Delta Frequency	0.449	0.291	0.473	0.949	Hz

Table 12 shows the calculation of the maximum allowable delta frequencies for each of the interconnections. All adjustments to the maximum allowable change in frequency are made to include:

- adjustments for the differences between 1-second and sub-second Point C observations for frequency events,
- adjustments for the differences between Point C and Value B, and

[48] The highest UFLS setpoint in the Eastern Interconnection is 59.7 Hz in FRCC, based on internal stability concerns. The FRCC concluded that the IFRO starting frequency of the prevalent 59.5 Hz for the Eastern Interconnection is acceptable in that it imposes no greater risk of UFLS operation in FRCC for an external resource loss event than for an internal FRCC event.

[49] CB_R value for the Eastern Interconnection limited to 1.0 because values lower than that indicate the Value B is lower than Point C and does not need to be adjusted. The calculated value is 0.989.

[50] Based on Québec UFLS design between their 58.5 Hz UFLS with 300 ms operating time (responsive to Point C) and 59.0 Hz UFLS step with a 20-second delay (responsive to Value B or beyond).

[51] DF_{CC}/CB_R

- adjustments for the event nadir being below the Value B (Eastern Interconnection only) due to primary frequency response withdrawal.

Recommendation – The determination for the Maximum Delta Frequencies should be calculated in accordance with the methods embodied in Table 12 – Determination of Maximum Delta Frequencies.

Largest N-2 Event

Table 13 shows the determination of IFROs based on a resource loss equivalent to the largest N-2 event in each interconnection. This calculation has been adjusted to include the recommended adjustment for the differences between Value B and Point C, and for the differences in measurement of Point C using 1-second and sub-second data.

Table 13: Largest N-2 Event

	Eastern	Western	ERCOT	Québec	Units
Starting Frequency	59.974	59.976	59.963	59.972	Hz
Max. Delta Frequency	0.449	0.291	0.473	0.949	Hz
Resource Contingency Protection Criteria	3,854	2,740	2,750	1,700	MW
Credit for LR		300	1,400		MW
IFRO[52]	-858	-840	-286	-179	MW/0.1Hz
Absolute Value of IFRO	858	840	286	179	MW/0.1Hz
% of Current Interconnection Performance[53]	34.8%	71.2%	48.7%	23.9%	
% of Interconnection Load[54]	0.14%	0.56%	0.45%	0.50%

[58] IFRO = ——————————

[59] Current Interconnection Frequency Response Performance: EI = -2,467 MW / 0.1Hz, WI = -1,179 MW / 0.1Hz, TI = -586 MW / 0.1Hz, and QI = -750 MW/0.1 Hz.

[60] Interconnection projected Total Internal Demands from the 2010 NERC Long-Term Reliability Assessment: EI = 604,245 MW, WI = 148,895 MW, TI = 63,810 MW, and QI winter load = 36,000 MW.

Recommended IFROs

Table 16 shows the determination of IFROs based on a resource loss equivalent to the recommended criteria in each interconnection. This calculation has been adjusted to include the recommended adjustment for the differences between Value B and Point C, and for the differences in measurement of Point C using 1-second and sub-second data.

Recommendation – The Interconnection Frequency Response Obligations should be calculated as shown in Table 16 – Recommended IFROs.

Table 16: Recommended IFROs

	Eastern	Western	ERCOT	Québec	Units
Starting Frequency	59.974	59.976	59.963	59.972	Hz
Max. Delta Frequency	0.449	0.291	0.473	0.949	Hz
Resource Contingency Protection Criteria	4,500	2,740	2,750	1,700	MW
Credit for LR		300	1,400		MW
IFRO[61]	-1,002	-840	-286	-179	MW/0.1Hz
Absolute Value of IFRO	1,002	840	286	179	MW/0.1Hz
% of Current Interconnection Performance[62]	40.6%	71.2%	48.7%	23.9%	
% of Interconnection Load[63]	0.17%	0.56%	0.45%	0.50%	

Special IFRO Considerations

The IFRO calculation scenarios for the Western Interconnection do not take into account intentional tripping of generation during the operation of remedial action schemes (RAS). A key example is the Pacific Northwest RAS for loss of the Pacific DC Intertie (PDCI), which trips up to 3,200 MW of generation in the Pacific Northwest when the PDCI trips, depending on the loading of the PDCI. The RAS is intended to avoid system instability, tripping generation, inserting the Chief Joseph braking resistor (for up to 30 cycles), and other reactive configuration

[61] IFRO = ———————————

[62] Current Interconnection Frequency Response Performance: EI = -2,467 MW / 0.1Hz, WI = -1,179 MW / 0.1Hz, TI = -586 MW / 0.1Hz, and QI = -750 MW/0.1 Hz.

[63] Interconnection projected Total Internal Demands from the 2010 NERC Long-Term Reliability Assessment: EI = 604,245 MW, WI = 148,895 MW, TI = 63,810 MW, and QI winter load = 36,000 MW.

changes. However, because the generation in the Pacific Norwest is some of the most responsive to frequency deviations in the Western Interconnection, the RAS also blocks frequency response by a number of generators and Balancing Authorities to avoid overloading the Pacific AC ties (such as the California–Oregon Interface (COI)).

Frequency events caused by the 3,200 MW generation trips from that RAS have not been considered historically as candidate events for the Western Interconnection calculation of frequency bias settings by the Balancing Authorities because of the response blocking. However, from an interconnection perspective, the frequency of the interconnection still must be maintained as a whole, regardless of which Balancing Authorities are responding to the event. This creates a dilemma when calculating an IFRO for the interconnection—the resultant resource loss is larger than the design loss criteria of two Palo Verde units (2,440 MW). Table 17 shows a comparison of the two resource losses in calculating the IFRO for the Western Interconnection.

Table 17: Western Interconnection IFRO Comparison

	2-PV	PNW RAS	Units
Starting Frequency	59.976	59.976	Hz
Max. Delta Frequency	0.291	0.291	Hz
Resource Contingency Protection Criteria	2,740	3,200	MW
Credit for LR	300		MW
IFRO[64]	-840	-1,101	MW/0.1Hz
Absolute Value of IFRO	840	1,101	MW/0.1Hz
% of Current Interconnection Performance[65]	71.2 %	93.4 %	
% of Interconnection Load[66]	0.56 %	0.74 %	

Using a 3,200 MW resource loss criterion in the IFRO calculation increases the obligation by 260 MW but is further complicated when that obligation is allocated to the Balancing Authorities in the interconnection; allocation of FRO to Balancing Authorities whose response is blocked by the RAS is inappropriate. Therefore, a different FRO allocation would be necessary for that IFRO.

Recommendation – NERC and the Western Interconnection should analyze the FRO allocation implications of the Pacific Northwest RAS generation tripping of 3,200 MW.

[64] IFRO = ——————————

[65] Current Interconnection Frequency Response Performance: WI = -1,179 MW / 0.1Hz.

[66] Interconnection projected Total Internal Demands from the 2010 NERC Long-Term Reliability Assessment: WI = 148,895 MW.

Comparison of IFRO Calculations

Table 18 shows a comparison of the four criteria analyzed by the TIS, as well as the criteria recommended by the NERC Resources Subcommittee (RS) in their white paper on frequency response. The table also compares the IFROs to current levels of frequency response performance[67] for each of the interconnections. A comparison is also made to IFROs adjusted to include the recommended adjustment for the differences between Value B and Point C.

Table 18: IFRO Calculation Comparison

Allocation of IFRO to Balancing Authorities

The allocation of the IFRO to individual Balancing Authorities in a multi-Balancing Authority interconnection will be done in accordance with the "Attachment A – BAL-003-1 Frequency Response and Frequency Bias Setting Supporting Document," which can be found at:

http://www.nerc.com/docs/standards/sar/Att_A_Freq_Response_Standard_Support_Document_100611.pdf)

The process is paraphrased here for brevity.

Once the IFROs have been calculated by the ERO, the FRO for each Balancing Authority in a multi-Balancing Authority interconnection is allocated based on the Balancing Authority's annual load and annual generation to each Balancing Authority by the following formula:

$$FRO_{BA} = FRO_{Int} X \frac{AnnualGen_{BA} + AnnualLoad_{BA}}{AnnualGen_{Int} + AnnualLoad_{Int}}$$

Where:

- Annual Gen_{BA} is the total annual "Output of Generating Plants" within the Balancing Authority Area (BAA), on FERC Form 714, column C of Part II – Schedule 3.
- Annual $Load_{BA}$ is total annual load within the BAA, on FERC Form 714, column E of Part II – Schedule 3.
- Annual Gen_{Int} is the sum of all Annual Gen_{BA} values reported in that interconnection.
- Annual $Load_{Int}$ is the sum of all Annual $Load_{BA}$ values reported in that interconnection.

The data used for this calculation is from the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which used data from 2011. Balancing Authorities that are not FERC-jurisdictional will use the Form 714 instructions to assemble and submit equivalent data to the ERO for use in the FRO allocation process.

Balancing Authorities that elect to form a Frequency Response Sharing Group (FRSG) will calculate an FRSG FRO by summing the individual Balancing Authority FROs. Balancing Authorities that elect to form an FRSG as a means to jointly meet the FRO will calculate their FRM performance for the FRS Form 1 as follows:

- calculate a group NI_A and measure the group response to all events in the reporting year on a single FRS Form 1, or
- jointly submit each Balancing Authority's Form 1 with a summary spreadsheet that sums each participant's individual event performance.

Balancing Authorities that merge or transfer load or generation are encouraged to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation to the interconnection remains the same and so that Control Performance Standard (CPS) limits can be adjusted.

Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), frequency bias setting and frequency bias type (fixed or variable) to the ERO each year to allow the ERO to validate the revised frequency bias settings on FRS Form 1. If the ERO posts the official list of events after the date specified in the timeline below, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to submit FRS Form 1.

Once the ERO reviews the data submitted in FRS Form 1 and FRS Form 2 for all Balancing Authorities, the ERO will use FRS Form 1 data to post the following information for each Balancing Authority for the upcoming year:

- frequency bias setting
- Frequency Response Obligation (FRO)

A Balancing Authority providing Overlap Regulation will report the historic peak demand and generation of its combined Balancing Authorities' areas on FRS Form 1 as described in Requirement R4 of the BAL-003-1 standard.

Frequency Response Performance Measurement

Interconnection Process

The process for detection of candidate interconnection frequency events for use in frequency response metrics is described in the ALR1-12 Metric Event Selection Process contained in Appendix W. It is paraphrased here for brevity.

Frequency Event Detection, Analysis, and Trending (for Metrics and Analysis)

Interconnection frequency events are detected through a number of systems, including:

- FNet (Frequency monitoring Network) – FNet is a wide-area power system frequency measurement system that uses a type of phasor measurement unit (PMU) known as a Frequency Disturbance Recorder (FDR). FNet is able to measure the power system frequency, voltage, and angle very accurately at a rate of 10 samplers per second. The FNet system is currently operated by the Power Information Technology Laboratory at Virginia Tech and the University of Tennessee, Knoxville. FNet alarms are received by the NERC Situational Awareness staff and contain an estimate of the size of the resource or load loss and general location description based on triangulation between FDRs.
- CERTS–EPG Resource Adequacy Tool Intelligent Alarms – The Electric Power Group (EPG) operates the Resource Adequacy (RA) tool developed under the auspices of the Consortium for Electric Reliability Technology Solutions (CERTS). The RA tool uses 1-minute frequency and area control error (ACE) SCADA data transmitted to a NERC central database. The RA tool constantly monitors frequency and produces many Smart Alarms for a number of frequency change conditions, but most useful for frequency event detection is the short-term frequency deviation alarm, which indicates when there has been a significant change in frequency over the last few minutes, typically indicating a resource loss.
- CERTS–EPG Frequency Monitoring and Analysis (FMA) Tool – EPG also developed and operates the FMA tool that allows rapid analysis of frequency events, calculating the A, B, and C values for a frequency event in accordance with parameters set by the Frequency Working Group (FWG). Event selection criteria are further discussed in Appendix E of this report.

Those three systems are used in combination by NERC staff to detect and collect data about frequency excursions in the four North American interconnections. The size of resource losses is verified with the Regional Entities for events where FNet estimates of resource loss meet the following criteria:

- Eastern: >1,000 MW (60 mHz excursion)
- Western: >700 MW (80 mHz excursion)
- ERCOT: >450 MW (100 mHz excursion)

Events that are detected and meet the ALR1-12 metric criteria are then considered to be "candidate events" and are used by NERC to calculate interconnection frequency response metrics and trends. Those candidate events are also presented to the Frequency Working Group for consideration to be used as events for calculation of Balancing Authority frequency response and bias setting calculations in accordance with NERC Standard BAL-003-1.

Ongoing Evaluation

The process for detection of frequency events and the calculation of Values A, B, and C and the associated interconnection level metrics will undergo constant review in an effort to improve the process. NERC staff and the Frequency Working Group will perform that review at least annually.

Recommendation –NERC staff and the Frequency Working Group should annually review the process for detection of frequency events and the method for calculating A and B Values and Point C. The associated interconnection frequency event database, methods for calculating interconnection metrics on risks to reliability, the associated probabilities, and the calculation of the IFROs using updated data should also undergo review in an effort to improve the process. Throughout this process, NERC should strive to improve the quality and consistency of the data measurements.

Balancing Authority Level Measurements

A statistical analysis and evaluation was performed on field trial data with similar sample sizes to those specified in the draft Standard BAL-003-1 Frequency Response and Frequency Bias Setting. Field trial data was provided on FRS Form 1 for 2011 for 60 Balancing Authorities on the Eastern and Western Interconnections; the analysis was not performed for either of the single Balancing Authority interconnections, (i.e., ERCOT or Québec). Of the 60 Balancing Authorities that provided data, only 50 provided data of sufficient quality to be used in the analysis. Balancing Authorities that were excluded provided frequency data that was either obviously incorrect (i.e., frequency data in hertz instead of change in hertz) or frequency data that was uncorrelated to the frequency measured in an interconnection.

To protect the confidential nature of the data, the Form 1 data was normalized by dividing the change in actual net interchange by the Frequency Response Obligation (FRO) for each Balancing Authority, based on Interconnection Frequency Response Obligations (IFROs) of -1,215 MW/0.1 Hz and -836 MW/0.1 Hz for the Eastern and Western Interconnections, respectively.[69] This normalization method converts all of the data from the actual frequency response of the Balancing Authority to a per-unit frequency response value where 1.0 indicates that the frequency response is exactly equal to the Balancing Authority's FRO. The process also required the development of the some of the data that would appear on the equivalent of the CPS2 Bounds Report under this revised standard. The required data was extracted from FERC Form 714 reports for the year 2009 and was estimated for those Balancing Authorities that did

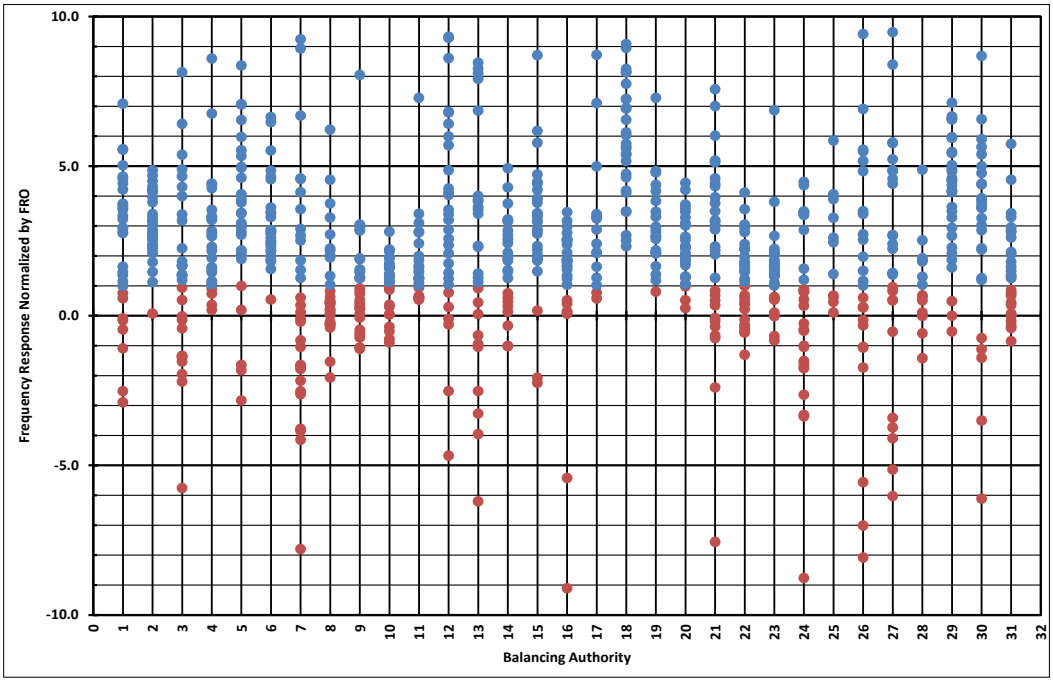
[69] As recommended by the Project 2007-12 Frequency Response Standards Drafting Team during the May 2012 Frequency Response Technical Conferences.

not submit 714 reports from equivalent data based on other sources. The validity of this analysis is not dependent upon the accuracy of the FRO estimates. It is only necessary for these estimates to be close to the actual values for firm conclusions to be drawn from the results and put the results in the proper context. Once the FROs were estimated for all of the Balancing Authorities on the Eastern and Western Interconnections, they were transcribed onto the FRS Form 1 for each Balancing Authority included in the analysis.

Single-Event Compliance

The question was posed whether or not a Balancing Authority's compliance with the proposed BAL-003-1 standard should be measured on each event, through use of the mean, median, or a regression analysis for a 12-month period. The variability of the measurement of frequency response for an individual Balancing Authority for an individual disturbance event was evaluated to determine its suitability for use as a compliance measure. The individual Balancing Authorities' performance disturbance events were normalized and plotted for each Balancing Authority on the Eastern and Western Interconnections.

Figure 34: 2011 Normalized Frequency Response Events by BA Eastern Interconnection

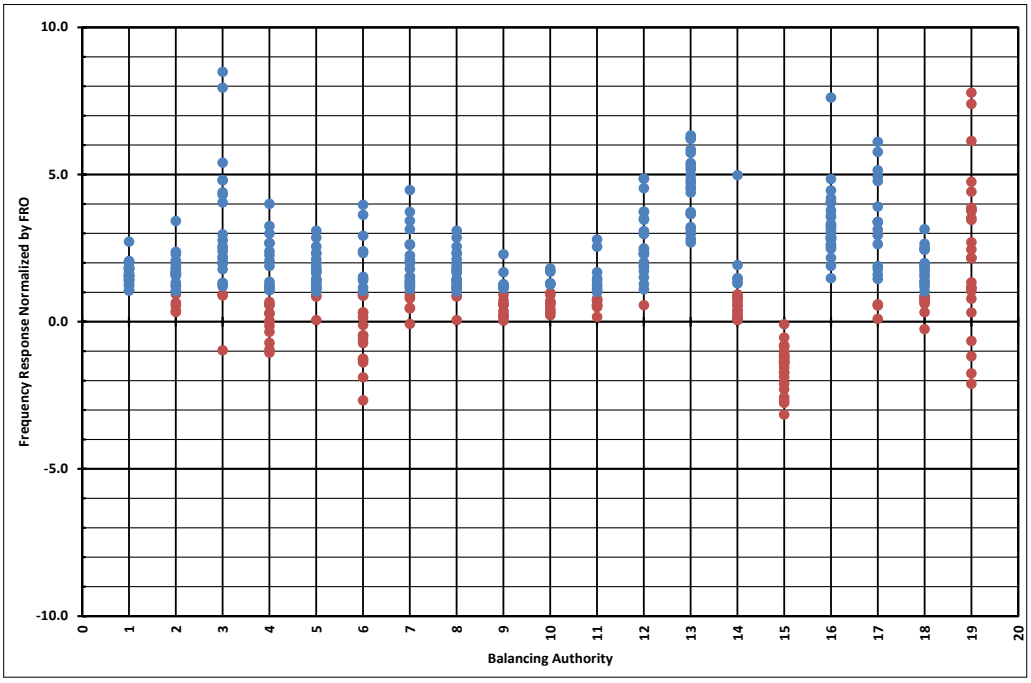


On Figures 34 and 35, events that had a measured Balancing Authority's frequency response above its FRO were shown as blue dots, and events that had a measured frequency response below its FRO were shown as red dots.

Analysis of this data indicates that a single-event-based compliance measure is unsuitable for compliance evaluation when the data has the large degree of variability shown in the charts in Appendix 1. Based on the field trial data provided, only three out of 19 Balancing Authorities in the sample (16%) would be compliant for all events with a standard based on a single event

measure on the Western Interconnection. Only one out of 31 Balancing Authorities in the sample (3%) would be compliant for all events with a standard based on a single-event measure on the Eastern Interconnection.

Figure 35: 2011 Normalized Frequency Response Events by BA Western Interconnection



Finding – Analysis of the field trial data indicates that a single-event-based compliance measure is unsuitable for compliance evaluation when the data has a large degree of variability.

Recommendation – Balancing Authority compliance with BAL-003-1 should not be judged on a per-event basis. Doing so would cause almost 90% of the Balancing Authorities to be out of compliance.

Balancing Authority Frequency Response Performance Measurement Analysis

Data provided by the Balancing Authorities from the field trial were also analyzed to determine: 1) if the sample size minimum of 20–25 frequency events, as specified for FRM calculation of the draft BAL-003-1 standard, is sufficient to provide stable measurements results; and 2) which of the three candidate FRM measurement methods is most appropriate. These analyses were carried out using the normalized data provided by a number of Balancing Authorities during the field trial.

Event Sample Size

Previous studies have recommended a sample size sufficient to provide a stable measure of frequency response of 20–25 events. These previous studies were performed on limited data and a limited number of Balancing Authorities. The field trial data set is sufficiently large to allow conclusions to be drawn with respect to that sample size recommendation specified for FRM calculation in the draft standard.

Review of the full set of graphs (Appendix H) indicates that the outlier problem, as previously described, did not present itself. There were no Balancing Authorities that had a small degree of variability in the measured single-event frequency response for most of the events that contained a few outliers.

The variability appeared similar for all events for each Balancing Authority, which indicates that the sample size of 20–25 events was sufficient to stabilize the result and eliminate any undue influence from potential outliers. In those Balancing Authorities with large variations in measured single-event response, the sample size was large enough that no single outliers unduly influenced the result. Balancing Authorities with large measurement variation still had enough samples to mitigate the risk associated with outliers. This demonstrates that the sample size chosen was sufficient to stabilize all three methods of measuring FRM. Therefore, it can be concluded that none of the methods are unduly influenced by outliers and the selection of the measurement method should be based on other factors.

Finding – Analysis of data submitted by the Balancing Authorities during the field trial confirms that the sample size selected (a minimum of 20–25 frequency events) is sufficient to stabilize the result and alleviate the perceived problem associated with outliers in the measurement of Balancing Authority frequency response performance.

Measurement Methods – Median, Mean, or Regression Results

All of the normalized data were analyzed using all three candidate methods for measuring FRM.

median – Median is the numerical value separating the higher half of a one-dimensional sample, a one-dimensional population, or a one-dimensional probability distribution from the lower half. The median of a finite list of numbers is found by arranging all the observations from lowest value to highest value and picking the middle one. When the number of observations is even, there is no single middle value; the median is arbitrarily defined as the mean of the two middle values.

In a sample of data, or a finite population, there may be no member of the sample whose value is identical to the median (in the case of an even sample size), and, if there is such a member, there may be more than one so that the median may not uniquely identify a sample member. Nonetheless, the value of the median is uniquely determined with the usual definition. A median is also a central point that minimizes the arithmetic mean of the absolute deviations. However, a median need not be

uniquely defined. Where exactly one median exists, statisticians speak of "the median" correctly; even when no unique median exists, some statisticians speak of "the median" informally.

The median can be used as a measure of location when a distribution is skewed, when end values are not known, or when one requires reduced importance to be attached to outliers; e.g., because they may be measurement errors. A median-unbiased estimator minimizes the risk with respect to the absolute-deviation loss function, as observed by Laplace.[70] For continuous probability distributions, the difference between the median and the mean is never more than one standard deviation. Calculation of medians is a popular technique in summary statistics and summarizing statistical data, since it is simple to understand and easy to calculate. It also gives a measure that is more robust in the presence of outlier values than the mean.

mean – Mean is the numerical average of a one-dimensional sample, a one-dimensional population, or a one-dimensional probability distribution. A mean-unbiased estimator minimizes the risk (expected loss or estimate error) with respect to the squared-error loss function, as observed by Gauss.[71] The mean is more sensitive to outliers for the very reason that it is a better estimator; it minimizes the squared-error loss function.

linear regression – Linear regression is the linear average of a multi-dimensional sample, or a multi-dimensional population. A linear regression unbiased estimator minimizes the risk (expected loss or estimate error) with respect to the squared-error loss function in multiple dimensions, as observed by Gauss.[72] The linear regression is also sensitive to outliers for the very reason that it is a better estimator; it minimizes the squared-error loss function.

Important Considerations

The following issues are important to consider with respect to the selection of the best method for measuring frequency response.

two-dimensional measurement – Two-dimensional measurement of frequency response provides the best representation of the change in MWs divided by the change in frequency and is used to estimate the frequency bias setting, which indicates the frequency response in MWs provided at actual frequency as compared to scheduled frequency.

non-linear attribute of frequency response – The non-linear attribute of frequency response has been demonstrated on all of the North American interconnections and is an important consideration in the representation of frequency response.

[70] An absolute-deviation loss function is used to minimize the risk of estimate error when dealing with uniform distributions. Appendix 3 provides a description of Uniform Distributions and a derivation of the median.

[71] A squared-error loss function is used to minimize the risk when dealing with normal (Gaussian) distributions. Appendix 4 provides a description of normal (Gaussian) distributions and a derivation of the mean.

[72] Appendix H provides a derivation of the linear regression.

single best estimator – A single best estimator of frequency response is a necessary result for use in compliance evaluation.

linear system – A linear system[73] is assumed in the development of the individual Frequency Response Obligation for each Balancing Authority on a multiple Balancing Authority interconnection and is used to distribute the Interconnection Frequency Response Obligation among the Balancing Authorities on that interconnection. If the system is non-linear,[74] then it cannot be assumed that the total required Interconnection Frequency Response Obligation will be achieved when all Balancing Authorities provide their individual Frequency Response Obligations.

bi-modal distributions – Bi-modal distributions occur whenever a reconfiguration of Balancing Authorities occurs within a compliance year. Unless the method chosen can correctly represent bi-modal distributions, reconfigured Balancing Authorities cannot be effectively measured for compliance.

quality statistics – Quality statistics should be available for use in compliance evaluation. Frequency response is used to determine compliance with minimum provision of the Balancing Authority's obligation for providing its share of frequency response for the interconnection. When using a measure for compliance, one must ensure that the measure fairly represents the Balancing Authority's performance. There is still a presumption that an indication of non-compliance should not occur due to pure chance.

reducing influence of noise – Reducing influence of noise in the data is considered an important attribute in the measurement method. All measurements of frequency response will be affected by noise in the measurement process.

reducing influence of outliers – Reducing influence of outliers in the data is considered the most important attribute in the measurement method. All measurements of frequency response will be affected by true outliers. The risk associated with the reduction in the influence of outliers is that valid information about the measure is also lost when an outlier reduction method is used.

ease of calculation and familiar indicators – Ease of calculation and familiar indicators are important considerations for communication and to promote ease of understanding by the industry.

Appendix H presents the series of graphs indicating results for each Balancing Authority. Each graph shows all of the individual data points use to determine the median, mean, and regression lines.

[73] A linear system is a system in which the sum of the parts is equal to the whole.

[74] A non-linear system is a system in which the sum of the parts is not equal to the whole.

The median line is green, the mean line is blue, and the regression line is red. The value of the normalized frequency response (vertical axis) where the line intercepts the value of frequency (horizontal axis) at a value of 0.1 Hz indicates compliance. Values above 1.0 indicate an FRM above the FRO, and values below 1.0 indicate an FRM below the FRO.

Figure 36 shows an example of a Balancing Authority with a small degree of variability in the measured frequency response for each individual event.

Figure 36: BA with Small Degree of Variability in Measured Frequency Response

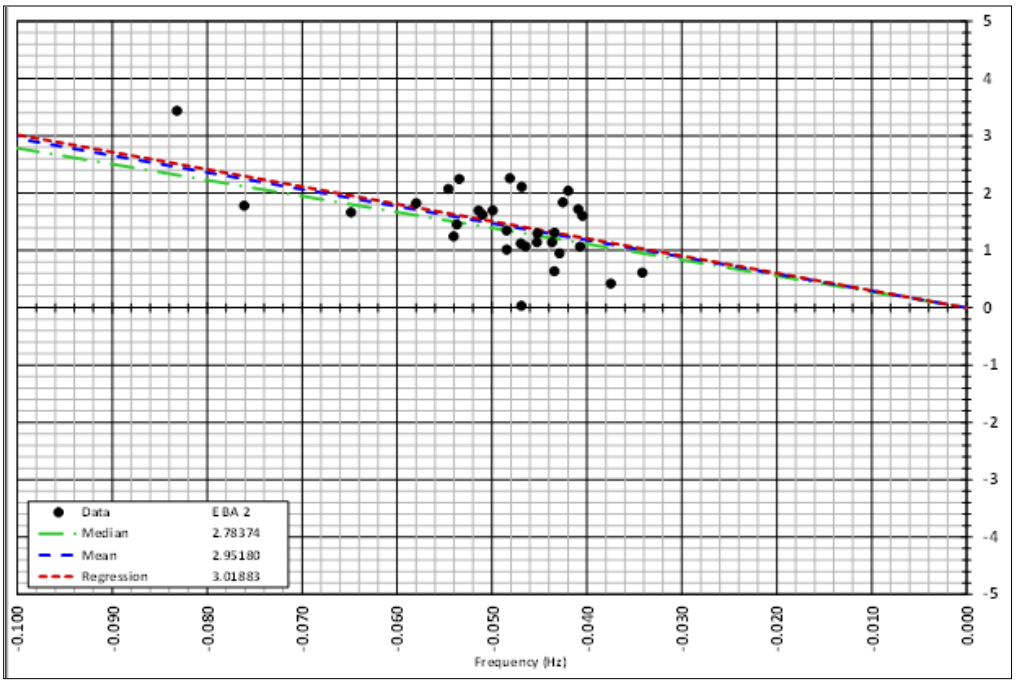


Figure 37 shows an example of a Balancing Authority with a large degree of variability in the measured frequency response for each individual event.

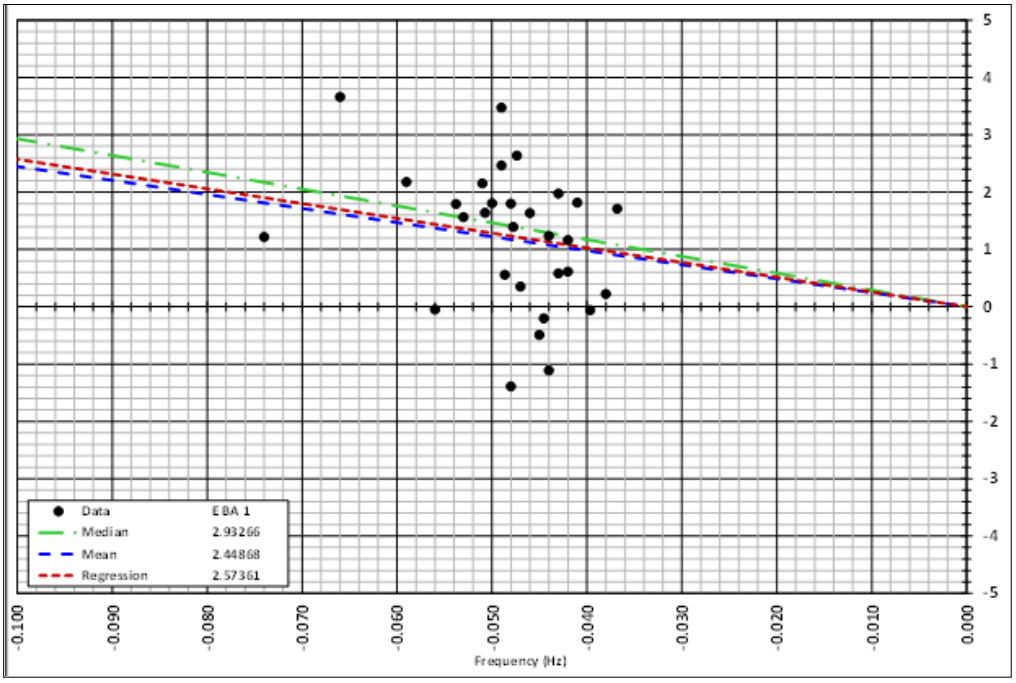
During the analysis, the graphs appeared to show that the regression provided a higher estimate of FRM than the median. Consequently, a comparison was made between the FRM as measured by the median and the FRM as measured by the regression. The results of the regression analysis demonstrate a performance for all samples that is 0.087% of their FRO higher than the median's performance on the Eastern Interconnection and 0.117% of their FRO higher than the median's performance on the Western Interconnection. In an unbiased analysis, one would expect the median and regression to yield the same result. This indicates there is an unknown statistical bias affecting the results of the analysis.

Figure 37: BA with Large Degree of Variability in Measured Frequency Response

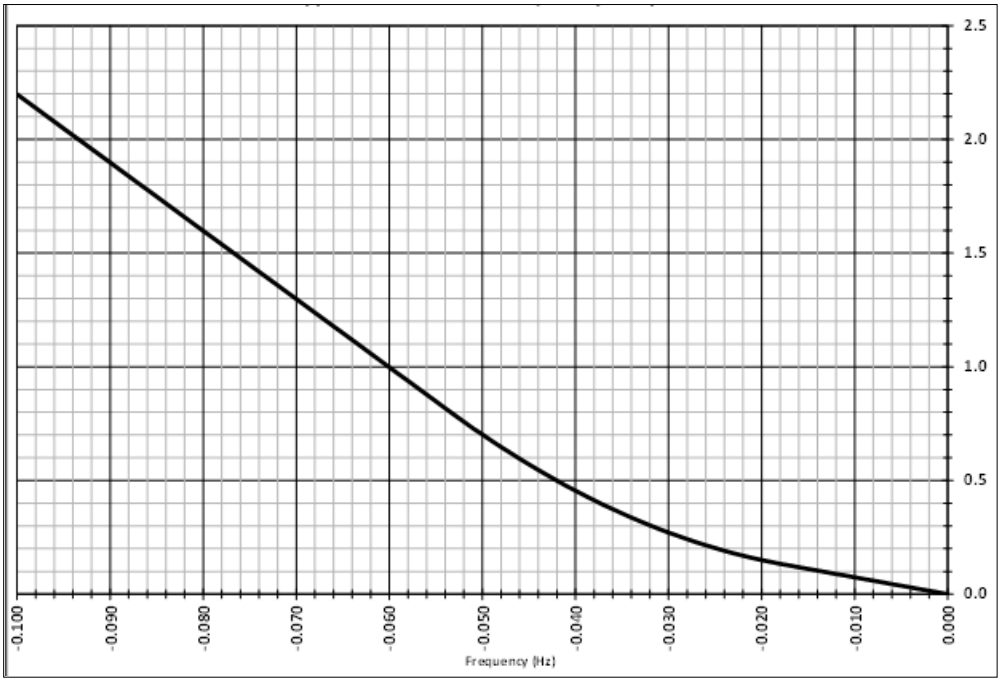


The bias causing the difference between the median and regression results can be explained by an attribute of frequency response. As the frequency deviation increases for larger disturbance events, the frequency response increases, but it does so disproportionately, shown in figure 38. This attribute of frequency response has been demonstrated in technical papers.[75] It has also been implemented in the variable frequency bias settings used by ERCOT, BPA and BC Hydro. In simple terms, the regression includes the effect of this non-linear attribute and the median does not.

The regression accommodates the disproportion on the slope of the regression line. In this case the effect tends to be upward—ever bigger MWs per increment in size of larger frequency error. The median is biased against any disproportionate increase in response per increase in size of frequency error as part of the median's blindness to outliers. The median will give no credit for the ever-growing amount of MWs deployed per added increment in size of frequency error. All the median does is count the number of MW responses regardless of size and, to represent all the MW responses, choose the one that occurred half-way in the sequence of decreasingly negative and increasingly positive frequency errors. Therefore, the median underestimates the FRM because it cannot evaluate the non-linear attribute correctly. It does not see or notice that attribute at all through its blinders regardless of numerical order or placement in a sequence. Regression is the only measurement method that captures the non-linear frequency response correctly.

[75] Hoffman, Stephen P., Frequency Response Characteristic Study for ComEd and the Eastern Interconnection, Proceedings of the American Power Conference, 1997. Kennedy, T., Hoyt, S. M., Abell, C. F., Variable, Non-linear Tie Line Frequency Bias for Interconnected Systems Control, IEEE Transactions on Power Systems, Vol. 3, No. 3, August 1988.

Figure 38: Typical Non-Linear Frequency Response



The advantages of each method of measurement are presented in Table 20 – Median, Mean and Regression Comparison. The alphabetic key is below.

Table 20: Median, Mean, and Regression Comparison

Attribute	Median	Mean	Regression
Provides two-dimensional measurement	A	A	Yes
Represents non-linear attributes	B	B	Yes
Provides a single best estimator (single value)	C	Yes	Yes
Is part of a linear system		Yes	Yes
Represents bi-modal distributions	D	Yes	Yes
Quality statistics available	E	Yes	Yes
Reducing influence of noise	Yes (F)		Partial (G)
Reducing influence of outliers	Yes		Partial (H)
Easy to calculate	Yes	Yes	I
Familiar indicator	Yes	Yes (J)	No
Currently used as the measure in BAL-003-1	No	Yes	No

A. Neither median nor mean can evaluate the two-dimensional nature of frequency response.

B. Neither median nor mean can capture the non-linear attribute of frequency response. Both underestimate the typical non-linear frequency response.

C. Median is arbitrarily defined as the average of the two central values when there is an even number of values in the data set. The decision to further constrain this central range of values to a single value that is the average of the ends of that range is unsupported by any mathematical construct. It is only the desire of those looking for simplicity in the result that supports this singular definition of median.

D. The median fails to provide a valid estimate of frequency response when the distribution of frequency event responses is bi-modal due to Balancing Authority reconfiguration or changes in responsibility for control such as partial-period overlap of supplemental control.

E. The median fails to provide any methods to determine the quality, significance, or confidence associated with the measure.

F. The median reduces the influence of noise in the data, but that noise reduction comes with the cost of eliminating the availability of any quality statistics.

G. Linear regression provides a result that weights the data according to the change in frequency. Since the noise in the data is independent of change in frequency, linear regression provides a method superior to the mean for reducing the influence of noise in the resulting estimate of frequency response.

H. Linear regression is less sensitive to outliers and large data errors than the mean.

I. Linear regression is more complex and requires more effort to calculate, but that additional effort is small when the evaluation process has been automated.

J. Mean is currently used as the measure in the proposed draft BAL-003-1 standard.

After consideration of the mitigating effects of the sample size with respect to outliers, the linear regression method is the preferred method for calculating the frequency response Measure (FRM) for Balancing Authorities for compliance with proposed NERC Standard BAL-003-1 – Frequency Response.

Recommendation – Linear regression is the method that should be used for calculating Balancing Authority Frequency Response Measure (FRM) for compliance with Standard BAL-003-1 – Frequency Response.

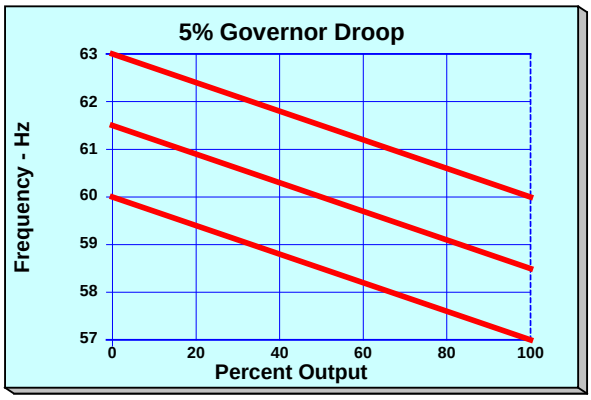
Role of Governors

Deadband and Droop

Turbine-generator units use turbine speed control systems, called governors, to control shaft speed by sensing turbine shaft speed deviations and initiating adjustments to the mechanical input power to the turbine. This control action results in a shaft speed change (increase or decrease). Since turbine-generators rotate at a variety of speeds, outside the power plant it is more appropriate to generally relate shaft speed to system frequency and throttle valve position to generator output power (MW).

The expected response of a turbine-generator's governor to frequency deviations is often plotted on what is known as a governor droop characteristic curve or a droop curve. The curve shows the relationship between the generator output and system frequency. The curve droops from left to right. Simply stated, as the frequency decreases, the generator's output will increase in accordance with its size.

Figure 39: Sample Droop Characteristic Curve



Droop settings on governors are necessary to enable multiple generators to operate in parallel while on governor control while not competing with each other for load changes. Droop is expressed as a percentage of the frequency change required for a governor to move a unit from no-load to full-load or from full-load to no-load. Prior to 2004, NERC Operating Policy 1, Generation Control and Performance, recommended generators with governor control (typically 10 MW and larger) to have a droop setting of 5% for steam turbine (and 4% for combustion turbines, although not explicitly stated in the policy). This means that a 3 Hz (5% of 60.00 Hz) change in system frequency is required to move a generator across its full range. Normally governors respond only to substantial frequency deviations.

Guidelines of the 2004 NERC Operating Policy 1, Generation Control and Performance, section C, stated:

1. Governor installation – Generating units with nameplate ratings of 10 MW or greater should be equipped with governors operational for frequency response unless restricted by regulatory mandates.
2. Governors free to respond – Governors should be allowed to respond to system frequency deviation unless there is a temporary operating problem.
3. Governor droop – All turbine-generators equipped with governors should be capable of providing immediate and sustained response to abnormal frequency excursions. Governors should provide a 5% droop characteristic. Governors should, at a minimum, be fully responsive to frequency deviations exceeding ±0.036 Hz (±36 mHz).
4. Governor limits – Turbine control systems that provide adjustable limits to governor valve movement (valve position limit or equivalent) should not restrict travel more than necessary to coordinate boiler and turbine response characteristics.

Within the Frequency Response Initiative, NERC is considering modifications to those parameters based on the recent advances in frequency response performance in ERCOT and revised governor control parameters.

In 2010, NERC conducted a survey of governor status and settings through Generator Owners and Generators Operators. The results of that survey are summarized in the Generator Governor Survey section of this report. A complete set of the summary graphics of the survey is contained in Appendix K.

ERCOT Experience

The general decline in primary frequency response in all interconnections has prompted regulatory entities to address the issue. Electric grids such as the one in Texas are especially sensitive to frequency regulation and response due to their relatively small overall interconnected capacity compared to the other interconnections. The Texas Regional Entity (TRE) is actively working on a regional standard for frequency regulation.

Frequency Regulation

Electric grid frequency regulation is attained by the response of the turbine governors to deviations from nominal synchronous speed, the operation of the boilers-turbine controls in response to the frequency change, and the actions of the dispatching system.

Frequency regulation success for any given boiler-turbine plant depends on many factors, primarily:

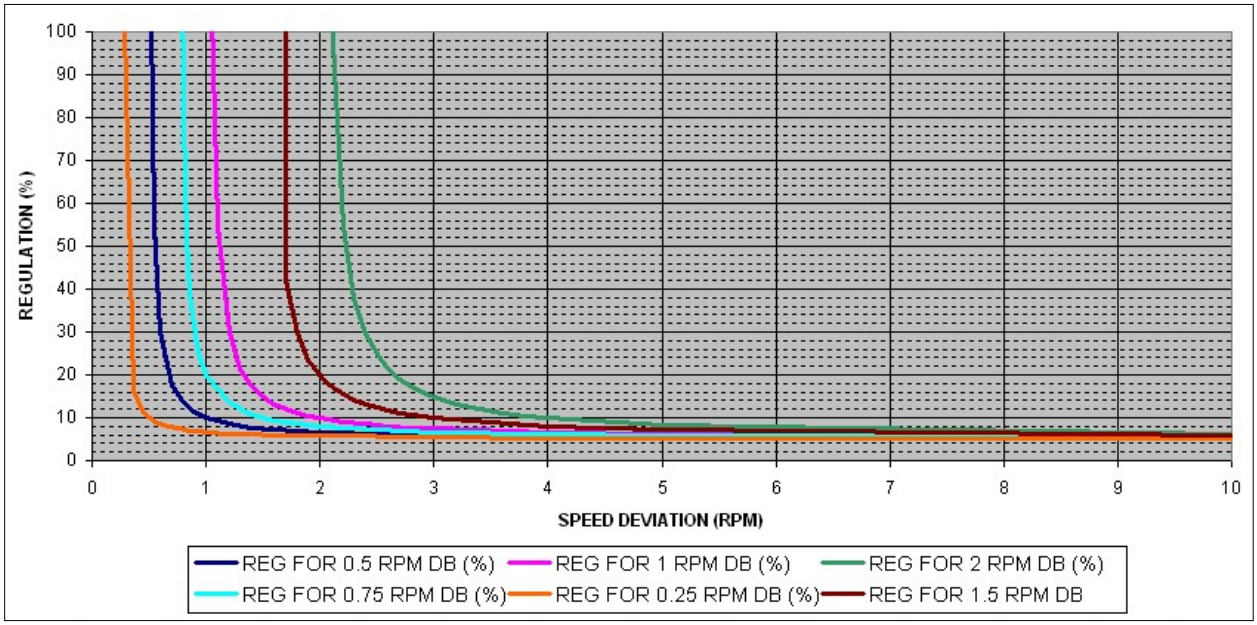
- steady state and dynamic stability of the unit
- load following capability
- linearization of turbine governor valves' steam flow characteristics
- proper calibration and coordination of the boiler and turbine frequency regulation parameters

- proper high and low limiting of the boiler and turbine frequency regulation based on unit conditions
- proper dispatching actions to restore the frequency to its normal operating value

Another factor that influences a unit's capability for frequency regulation is the available boiler energy storage. The larger the storage, the less the initial pressure drop caused by the quick opening of the governor valves, and the better the initial unit frequency regulation.

The standard speed regulation setting for the turbine governors of the boiler-turbine generating units is 5%. This is a ±5% change from rated speed (0.05*3,600 = 180 RPM), which causes the turbine governor to change its valves' position demand ±100 percent. It is also generalized industry practice to add a small deadband (DB) to the calibration of the governor speed error bias in order to minimize the movement for very small speed deviations. The selection of the DB affects the fidelity of the regulation, as shown in figure 40.

Figure 40: Regulation versus RPM Deadbands



The regulation curves of figure 40 are for the noted speed regulation at constant pressure. They are calculated by developing the equation ΔGVD= f (ΔRPM) for each DB, where ΔGVD is the change in the turbine Governor Valve Demand as a function of the change in RPM.

Knowing the ΔGVD for any given ΔRPM enables the regulation calculation via the equation:

$$REG\ (\%) = (100 * \Delta RPM/\Delta GVD)*(100/3{,}600)$$

ERCOT Nodal Operating Guides Section 2 has specific requirements for governor deadband settings. The maximum allowable deadband is ±0.036 Hz, which has been the industry standard for mechanical "fly-ball" governors on steam turbines for many years. With the development

of energy markets in the early 2000s, generators with electronic or digital governors began implementing this same deadband in their primary frequency response implementation. Unfortunately, the Guides were not clear on how to implement the droop curve at the deadband. Since the Guides required 5% droop performance, many generators introduced a "step function" or modified "step" once the deadband was reached in order to achieve near 5% droop performance outside the deadband.

As can be seen in figure 40, a 2 rpm deadband on a 3,600 rpm turbine is equivalent to +/-0.033 Hz. Based on the corresponding droop (regulation percent) for this deadband, a generator's performance to typical frequency deviations during disturbances would be much greater than 5% without some "step" function. These governor settings resulted in an abnormal frequency profile for the interconnection.

Figure 41: Frequency Profile for March and September 2008 (in 5 mHz bins)

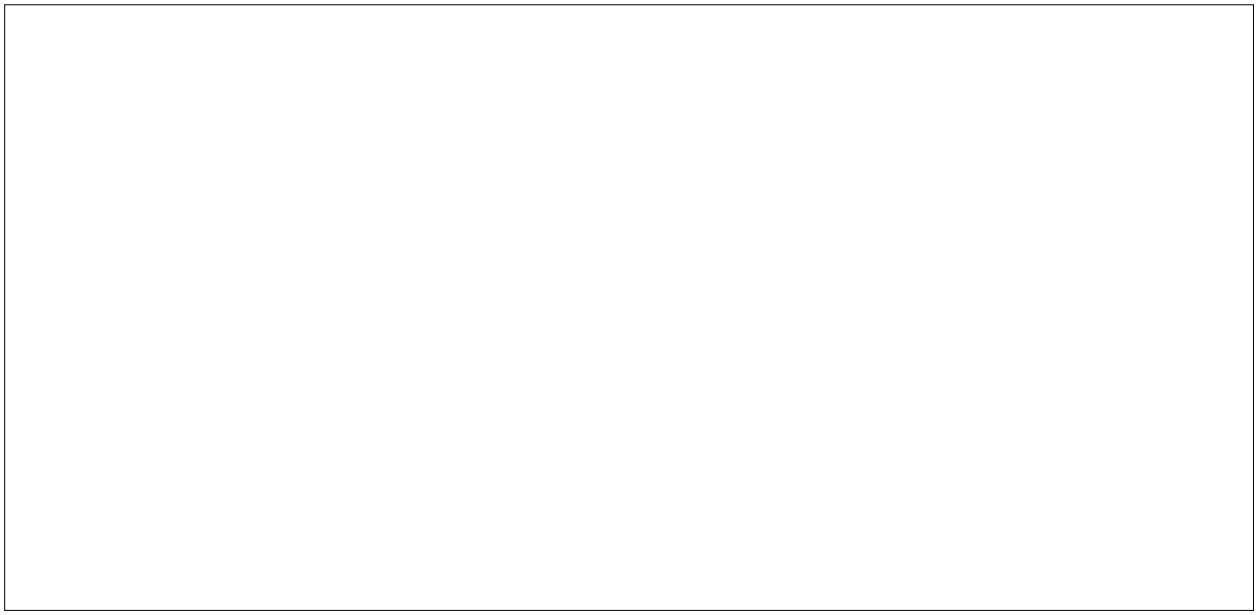


Figure 41 is the ERCOT frequency profile for March and September of 2008. It is clear that the "flat top" of the profile is centered on the ±0.036 Hz deadband. This flat frequency profile created significant problems because frequency spent as much time at the governor deadband points as it did at any point in between. This made it difficult to employ Frequency Regulation to correct frequency to 60 Hz, and for ERCOT to meet the NERC BAL-001-0 — Real Power Balancing Control Performance Requirement 1 (aka, CPS1), since ERCOT had an epsilon-1 limit of 0.030 Hz. The frequency profile also contributed to generator instability at the deadbands with the implementation of the various "step" functions in the governors.

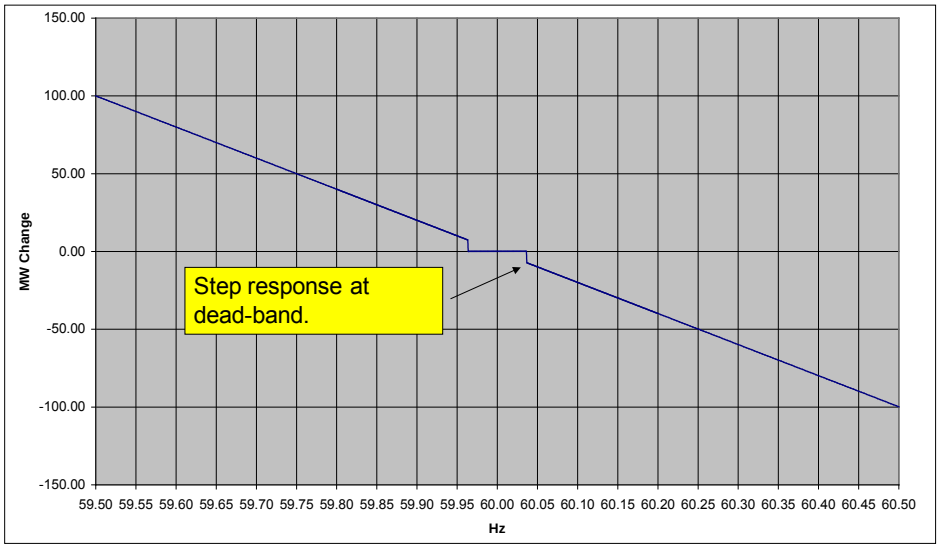
If generators that had implemented governor step functions were to be electrically separated from the grid during an islanding event, they would experience extreme instability. This would be caused by the governor providing excessive frequency response to the island to small generation load imbalances, resulting in large frequency swings and unit instability.

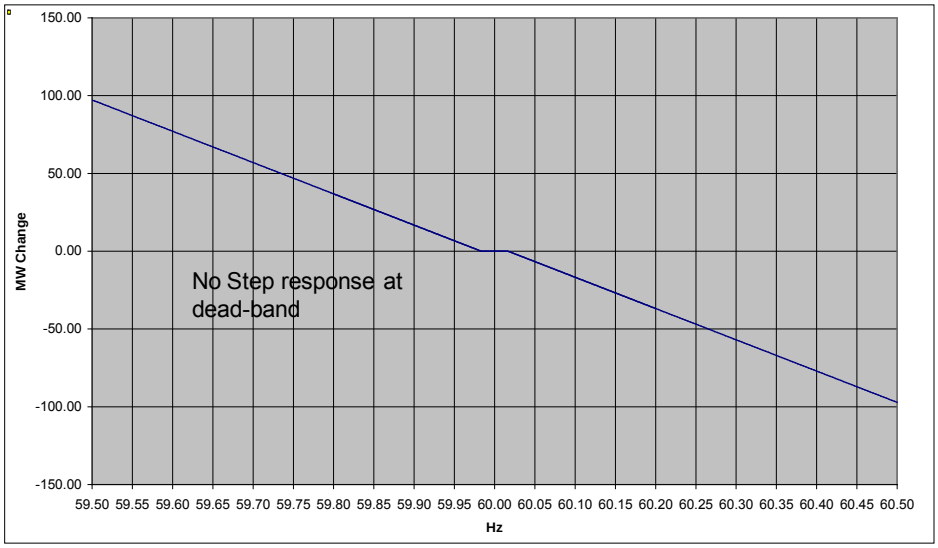
The ERCOT Performance Disturbance and Compliance Working Group (PDCWG) became increasingly concerned about the frequency instability and the realization of the risk of the step function in the governors (see figure 42). Because of their analysis, a member of the PDCWG discussed the issues with one large generating facility that was willing to try different deadband settings along with a specific droop curve implementation. This implementation required a straight linear curve from the deadband to full range of the governor, eliminating any step function shown in figure 43.

Figure 42: Frequency Response of 600 MW Unit ±36.0 mHz Deadband and Step Response



After brief testing of a number of different deadbands, a 1-rpm deadband (± 0.01666 Hz) was chosen. Four turbine governors were set in this manner on November 3, 2008 (about 2,500 MW capacity or 7.5% of the average grid capacity in November).

Figure 43: Frequency Response of 600 MW Unit ±16.67 mHz Deadband and No-Step Response



The possibility of leaving the deadband at ±0.036 Hz and just eliminating the stepped droop response was considered. Analysis showed that the droop performance at 59.900 Hz would be around 7.72% with a ±0.036 Hz deadband but only 5.97% droop with the ±0.0166 Hz deadband. That difference increases at 59.950 Hz, with a 17.64% droop performance for the ±0.036 Hz deadband and a 7.46% droop performance for the ±0.0166 Hz deadband. However, without the primary frequency response of the lower deadband, the frequency profile would return to the "flat top" frequency profile spanning the ±0.036 Hz deadbands, which is a less reliable state (less stable) for the interconnection. Also, with the larger deadband the interconnection or Balancing Authority may not have been able to meet the minimum frequency response requirements.

Turbine-Generator Performance with Reduced Deadbands

The general purpose for using governor deadbands is to minimize generator movement due to frequency regulation. In an interconnection where generators have various deadband settings, the diversity of settings creates diversity in responses to frequency changes. However, when a majority of the generators in an interconnection set the deadband the same and with a step function, the diversity of responses disappears, and frequency will move to the deadband frequently as demonstrated in the profile in figure 41. When the frequency exceeds the deadband, all units react with a stepped response simultaneously.

The amount of generator movement expected for a specific set of deadband settings can be compared by calculating the MW-minute average movement of a hypothetical generator exposed to actual measured frequency using the different governor settings.

Table 21 compares the movement of two generators with different governor settings: one with a ±0.036 Hz deadband and droop step function, and one with a ±0.01666 Hz deadband and no droop step function.

Table 21: Comparison of MW Movement for Response of Different Governor Settings

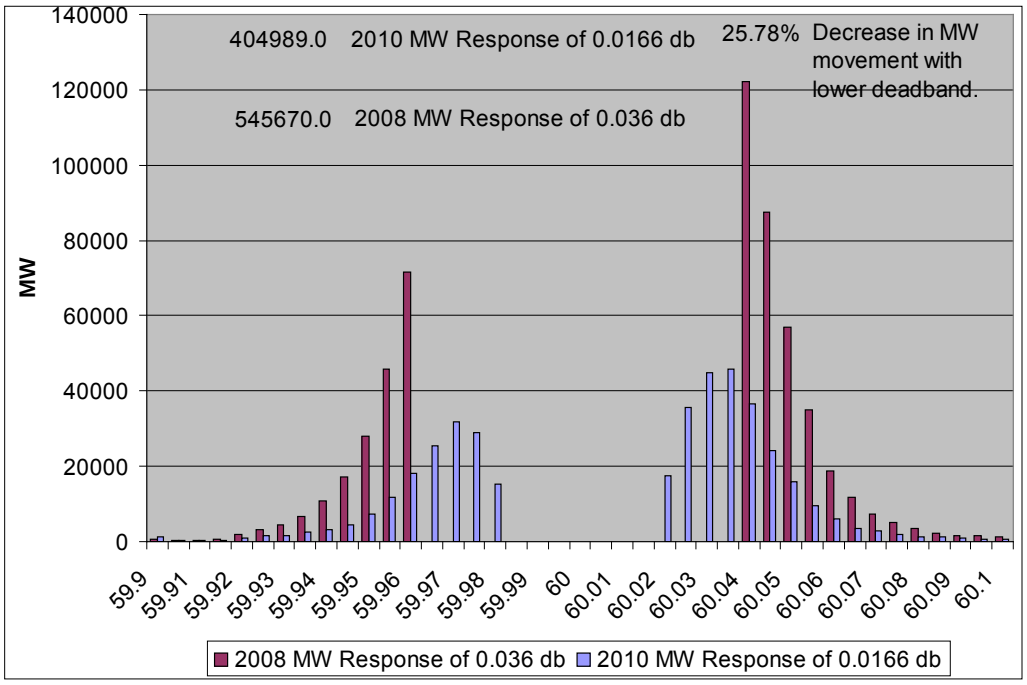
	±0.036 Hz Deadband with Droop Step Function	±0.01666 Hz Deadband with No Droop Step Function	Percent Increase for Smaller Deadband
2008 Frequency Profile	662,574.0 MW-min.	893,164.2 MW-min.	34.80%
2009 Frequency Profile	446,244.0 MW-min.	692,039.8 MW-min.	55.08%

Using the 2008 1-minute average frequency data, the generator with the lower deadband would have had 893,164.2 MW-minutes of primary frequency response while the generator with the larger deadband unit would have had 662,574.0 MW-minutes of primary frequency response. This is a 34.80% increase in movement for the lower deadband generator.

However, if the exact same comparison is made for ERCOT frequency data from 2009, where the new deadbands had an actual impact on frequency, the following observation scan be made. The lower deadband generator would have had 692,039.8 MW-minutes of primary frequency response compared to the larger deadband generator with 446,244.0 MW-minutes, a 55.08% increase in movement for the lower deadband. One observation is that the MW-minute movement of the lower deadband generator is only 4.45% higher than the movement of the larger deadband generator of the previous year (692,039.8 MW-minutes versus 662,574.0 MW-minutes).

Having the lower deadband in service for the entire year greatly reduced the frequency movement of the interconnection and reduced the primary frequency response movement as well. The lower deadband generator MW-minute movement decreased 201,124.4 MW-minutes, or 22.518%, between 2008 and 2009. This indicates the reduced impact on the generator movement with the smaller deadband and the non-step governor droop implementation when the governor becomes active, as compared to the "step" implementation.

Figure 44: MW-Minute Movement of a 600 MW Unit with 5% Droop



This benefit is further emphasized by the comparison in Figure 44, which shows the response of a theoretical 600 MW unit for the 2008 ERCOT frequency profile with a ±0.036 Hz deadband versus the same unit with a ±0.01666 Hz deadband for the 2010 frequency profile. Using the lower deadband, there is a savings of 140,641 MW-minutes of regulation movement because there were a larger number of generators using the ±0.01666 Hz deadband in 2010, which greatly influenced the frequency profile. Figure 45 shows a comparison of the actual January–September ERCOT frequency profiles for 2010 and 2008. The profile changed from a flat response between the ±0.036 Hz deadband to a more normal distribution.

Figure 45: ERCOT 2010 versus 2008 Frequency Profile (Jan.–Sept.)

Conclusion – The benefits of using the smaller ±0.01666 Hz deadband coupled with a non-step governor droop implementation results in the following:

- improved frequency response for small disturbances
- generators responding more often in smaller increments, saving fuel and wear and tear on turbines
- more stable operation when near boundary conditions of deadbands

Recommendation – NERC should embark immediately on the development of a Frequency Response Resource Guideline to define the performance characteristics expected of those resources for supporting reliability. That guideline should address appropriate parameters for:

Existing generator fleet – In order to retain or regain frequency response capabilities of the existing generator fleet, adopt:

deadbands of ±16.67 mHz,

droop settings of 3%-5% depending on turbine type,

continuous, proportional (non-step) implementation of the response,

appropriate operating modes to provide frequency response, and

appropriate outer-loop controls modifications to avoid primary frequency response withdrawal at a plant level.

Other frequency-responsive resources – Augment existing generation response with fast-acting electronically coupled frequency responsive resources, particularly for the arresting and rebound periods of a frequency event:

contractual high-speed demand-side response,

wind and photo-voltaic – particularly for over-frequency response,

storage – automatic high-speed energy retrieval and injection, and

variable speed drives – non-critical, short time load reduction.

Generator Governor Survey

On September 9, 2010, NERC issued a Generator Governor Information and Setting Alert (the alert) recommending that Generator Owners (GOs) and Generator Operators (GOPs) provide information and settings for turbine governors for all generators rated at 20 MVA or greater, or plants that aggregate to a total of 75 MVA or greater net rating at the point of interconnection (i.e., wind farms, PV farms, etc.). The alert was issued as a recommendation to industry, which requires reporting obligations (as specified in Section 810 of the Rules of Procedures) from industry to NERC and, subsequently, from NERC to FERC. Balancing Authorities in North America were the only functional group required to respond to this alert. A copy of the survey instructions is located in Appendix J of this report.

The survey requested three types of information:

1. policies on installation and maintenance, and testing procedures and testing frequency for governors;
2. unit-specific characteristics and governor settings; and
3. unit-specific performance information for a recent, single event.

NERC sent the survey instrument and instructions to 799 GOs and 748 GOPs in North America. Of the 794 GOs that acknowledged receipt of the survey, 749 developed and provided a response. Of the 743 GOPs that acknowledged receipt of the survey, 721 developed and provided a response.

Administrative Findings

NERC staff first reviewed the information submitted by the GOs and GOPs. This initial review led to the following findings from the administration of the survey:

1. There is a wide variety of levels of understanding among GOs and GOPs of the role of turbine governors in maintaining frequency response, including confusion in terminology and a lack of understanding of governor control settings. This indicates a need for education on settings and performance of turbine governors and the governor's role in interconnection frequency response.

Recommendation – NERC should address improving the level of understanding of the role of turbine governors through seminars and webinars, with educational materials available to GOs and GOPs on an ongoing basis.

2. There was a significant amount of duplication of reporting. This was mostly due to dual submittals by entities that are registered both as GOs and as GOPs. NERC staff sought to eliminate as much duplication as possible. However, eliminating duplication was difficult when the entities that own and operate a generator differ, yet both submitted information on the same generator. Hence, there remains some duplication in this analysis.

Summary of the Survey Responses

Table 22 summarizes, by interconnection, the aggregate characteristics of the generators analyzed.

Table 22: Number of Generators as Reported

Interconnection	Total	With Governors	Without Governors
Eastern	4,372 (648.7 GW)	4,217 (630.2 GW)	152 (18.5 GW)
Western	1,560 (171.6 GW)	1,445 (162.9 GW)	114 (8.7 GW)
ERCOT	503 (95.6 GW)	446 (85.6 GW)	53 (9.0 GW)
Totals	6,435 (915.9 GW)	6,110 (878.7 GW)	319 (36.2 GW)

Figures 46–48 summarize the responses on turbine governors for three of the interconnections. Data for the Québec Interconnection is not summarized in this report. The GOs and GOPs reported that governors were operational for 95%, 97%, and 99% of the total number of generating units that were reported as having governors in the Eastern, Western, and Texas Interconnections, respectively.

Figure 46: Eastern Interconnection Generator Responses

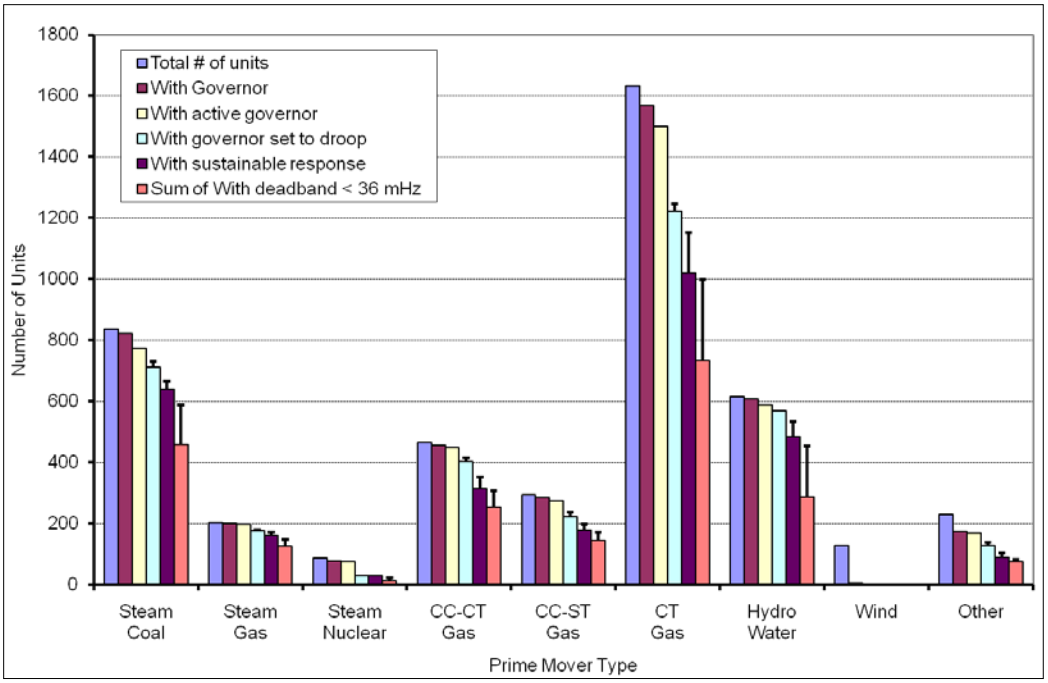


Figure 47: Western Interconnection Generator Responses

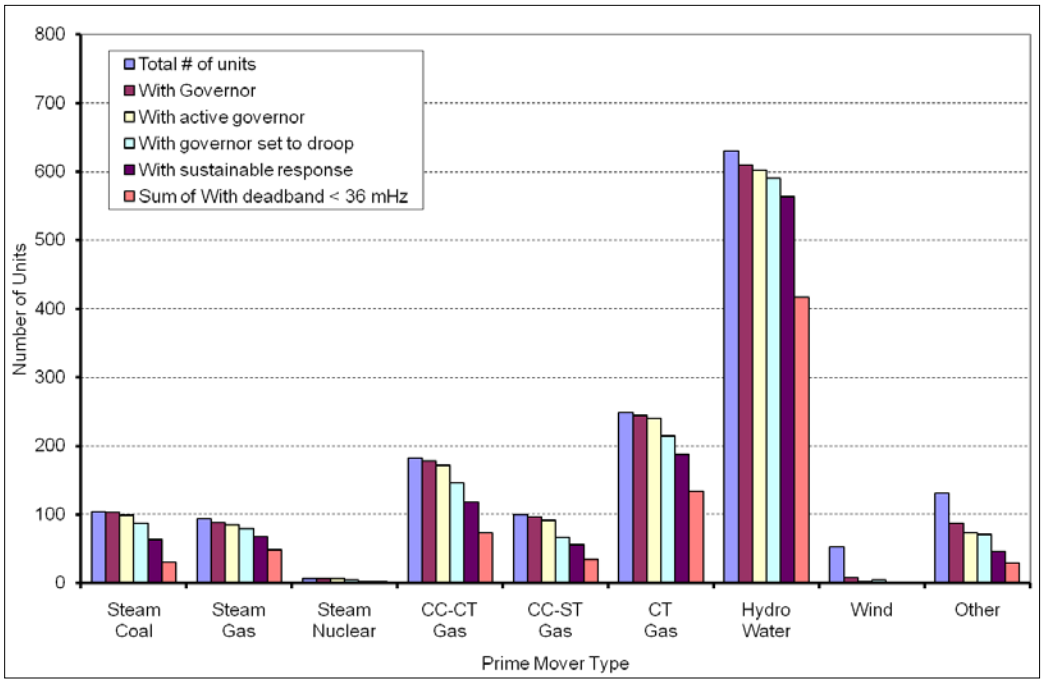

Figure 48: ERCOT Interconnection Generator Responses

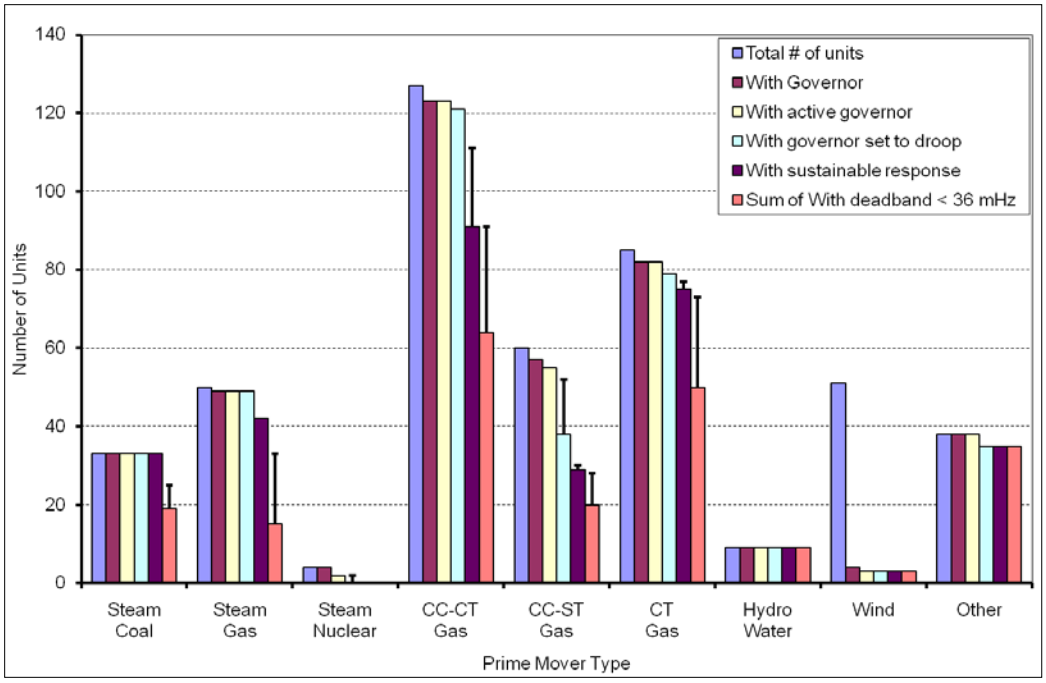

Reported Deadband Settings

The deadband setting of a governor establishes a minimum frequency deviation that must be exceeded before the governor will act. Frequency deviations that are less than the setting will not cause the governor to act. Of the information provided by the GOs and GOPs on governor deadbands, 51%, 63%, and 79% of the number of units in the Eastern, Western, and Texas Interconnections, respectively, was usable. Figure 49 summarizes the usability of the deadband data submitted in the survey.

Figure 49: Usability of Information Provided on Governor Deadbands

Figure 50 summarizes the range of deadband settings reported by generating unit size for all three interconnections. The simple average, or mean, of the frequency response values calculated is indicated by the orange dot. A horizontal line inside the green box indicates the median of these values. The upper and lower boundaries of the box are the inter-quartile range, which is the range that contains half the calculated frequency response values. Finally, the end points of the upper and lower vertical lines indicate the lowest and highest calculated frequency response values, respectively.

The use of these descriptive statistics provides additional information on the distribution of values. For example, if the average is lower than the median, it means that the distribution has a small number of low values compared to the main body of values. Similarly, the height of the inter-quartile range (the top and bottom of the box) provides a measure of how widely the values are distributed. The location of the median within the box indicates whether values are evenly distributed on either side of the median (when the median is close to the center of the box) or whether values are disproportionately on one or the other side of the median (when the median is closer to the top or the bottom of the box).

Figure 50: Reported Governor Deadband Settings

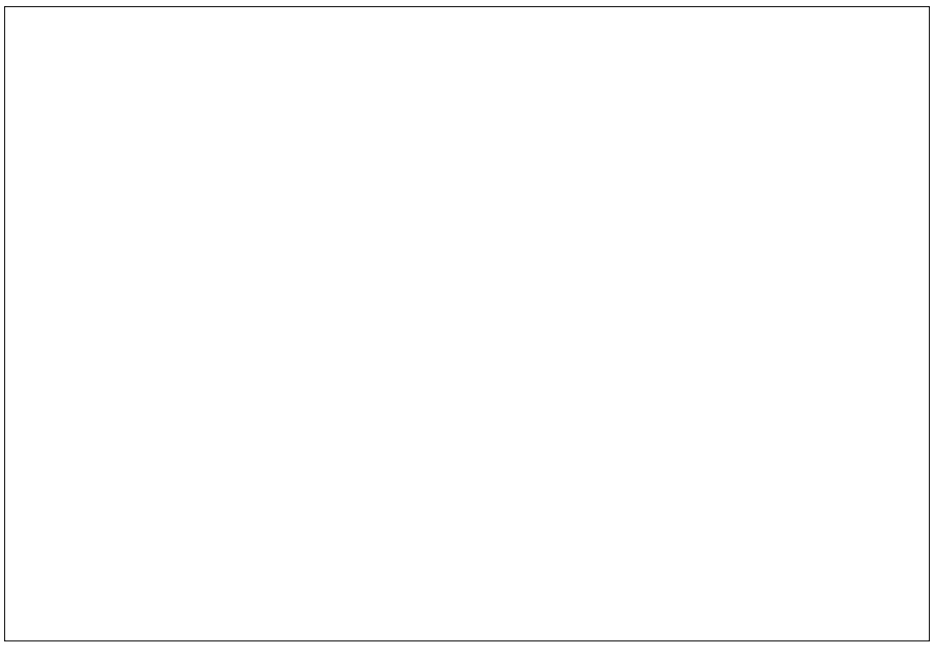

Figure 50 indicates:

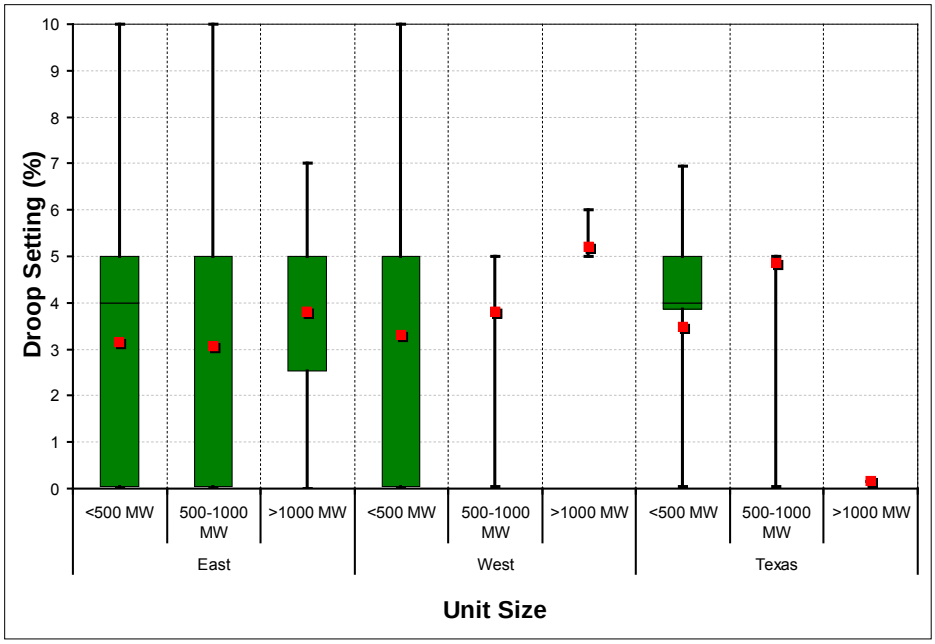
- Eastern Interconnection – Half of the deadband settings are between 0 and 100 mHz, with the smallest generating units having the lowest settings, followed by the mid-size, and then the largest units. The figure also indicates that there are a number of units in all size ranges with very high deadband settings (> 200 mHz).
- Western Interconnection – Half of the deadband settings are between 0 and 50 mHz for the smallest and mid-size generating units. However, the range is considerably broader for the largest units, with half of the settings lying between 0 and more than 300 mHz. The very large deadbands on units greater than 1,000 MW are attributable to the nuclear units.
- Texas Interconnection – The deadband settings are generally less than 50 mHz. There appears to be at least one very high deadband setting for a small generating unit.

Reported Droop Settings

Governor droop expresses the effect of changes in generating unit speed in terms of changes in power output as a function of the amount of frequency deviation from the reference frequency. Of the information provided by the GOs and GOPs on governor droop settings, 89%, 94%, and 87% of the number of units in the Eastern, Western, and Texas Interconnections, respectively, was usable.

Figure 51 summarizes the range of governor droop settings for the interconnections. Generally, the droop settings were in the range of expected values.

Figure 51: Range of Governor Droop Settings by Generating Unit Size



Governor Status and Operational Parameters

A number of the survey questions addressed the operational status and parameters of the governor fleet. As shown in Figure 52, the vast majority of the GOs and GOPs reported that their governors are operational.

Figure 53 shows that the governors also were reported to be able to sustain primary frequency response for longer than 1 minute if the frequency remains outside of its deadband. However, as shown in Figure 54, roughly half of the governors are expected to be overridden or limited by plant-level control schemes. This factor heavily influences the sustainability of primary frequency response, contributing to the withdrawal symptom often observed in the Eastern Interconnection, especially during light load periods.

Figure 52: Operational Status of Governors

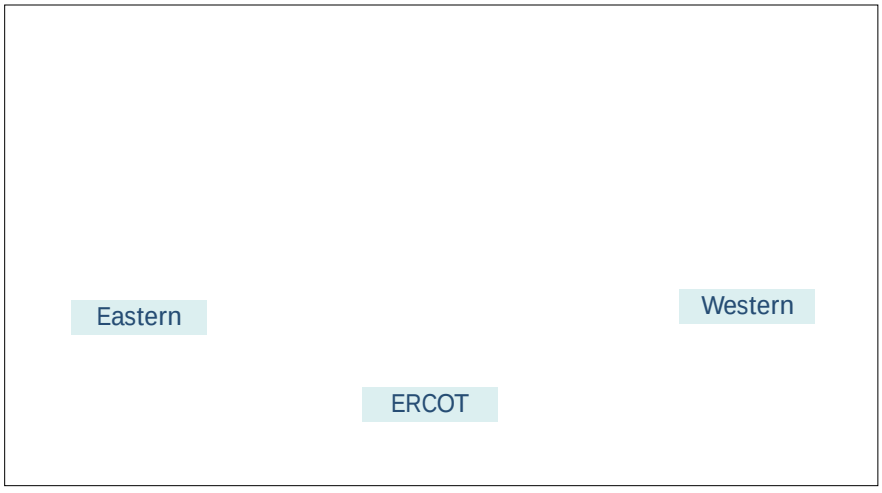


Figure 53: Response Sustainable for More Than 1 Minute if Outside Deadband

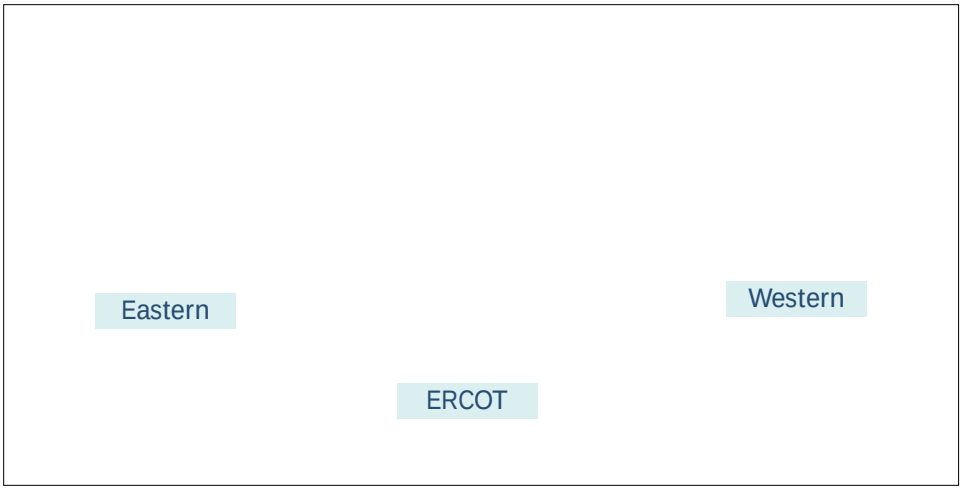

Figure 54: Unit-Level or Plant-Level Control Schemes that Override or Limit Governor Performance

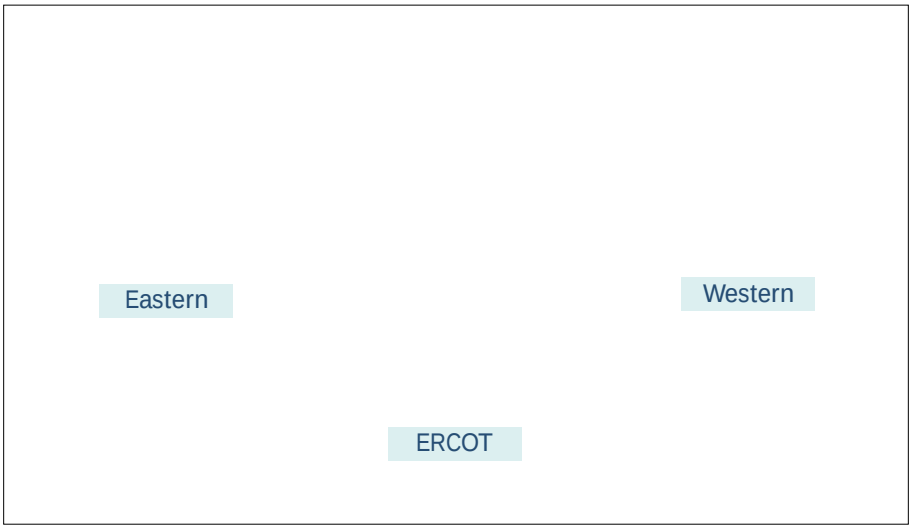

Response to Selected Frequency Events

The GOs and GOPs were asked to provide information on the performance of turbine governors during a selected event in each interconnection. Table 23 lists the date and time of the events selected for the Eastern, Western, and Texas Interconnections (data was not requested from the Québec Interconnection).

Table 23: Selected Events for Provision of Generator Governor Performance Information			
Interconnection	Basis		Frequency
Eastern	8/16/2010	1:06:15 CST	1,200 MW
Western	8/12/2010	14:44:03 CST	1,260 MW
ERCOT	8/20/2010	14:25:29 CST	1,320 MW

Of the interconnections' total generating capacity, 64%, 58%, and 75% of the units were on-line at the time of the event for the Eastern, Western, and Texas Interconnections, respectively.

Figure 55: Governor Response by Total Generating Capacity On-Line

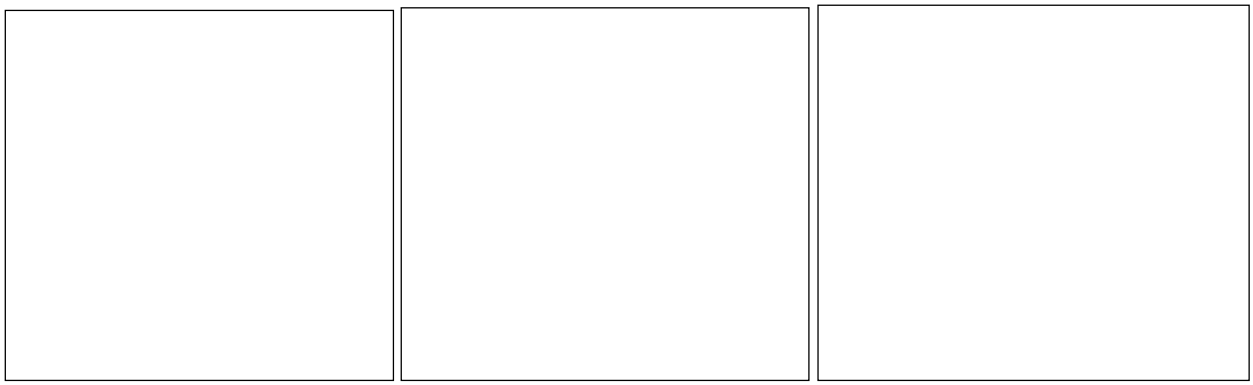

Figure 55 shows:

- Of the total generating capacity on-line, 30%, 44%, and 53% reported responding in the expected direction of response (i.e., to correct the change in frequency) for the Eastern, Western, and Texas Interconnections, respectively.
- Some generation reported no response to the frequency deviations (38%, 35%, and 13% for the Eastern, Western, and Texas Interconnections, respectively).
- Notably, 19%, 17%, and 20% were reported as responding in the opposite direction of the expected response (i.e., not in opposition to the change in frequency) for the Eastern, Western, and Texas Interconnections, respectively.

The values reported for the Eastern Interconnection for capacity providing expected response are in keeping with those calculated from the generic governor simulation of the frequency response to the August 4, 2007 Eastern Interconnection Frequency Disturbance. Those simulations showed that 30% of the capacity on-line responded, and 20% of the capacity on-line withdrew primary support, leaving only 10% of the capacity on-line providing sustained primary frequency response.

Figure 56 shows that for the Eastern Interconnection, total response in the expected direction was 973 MW, while response in the direction opposite expectations was -361 MW, for a total net response of 613 MW. Steam coal and combined-cycle gas turbine units, accounting for 327 MW and 244 MW of the net response, respectively, made the largest contributions. These contributions were made by steam coal and combine-cycle with a total on-line generating capacity of about 180 GW steam coal and about 60 GW combined-cycle gas turbine units, of which about 80 GW and about 10 GW of capacity provided response in the expected direction, respectively.

Figure 56: Eastern Interconnection Generator Governor Performance

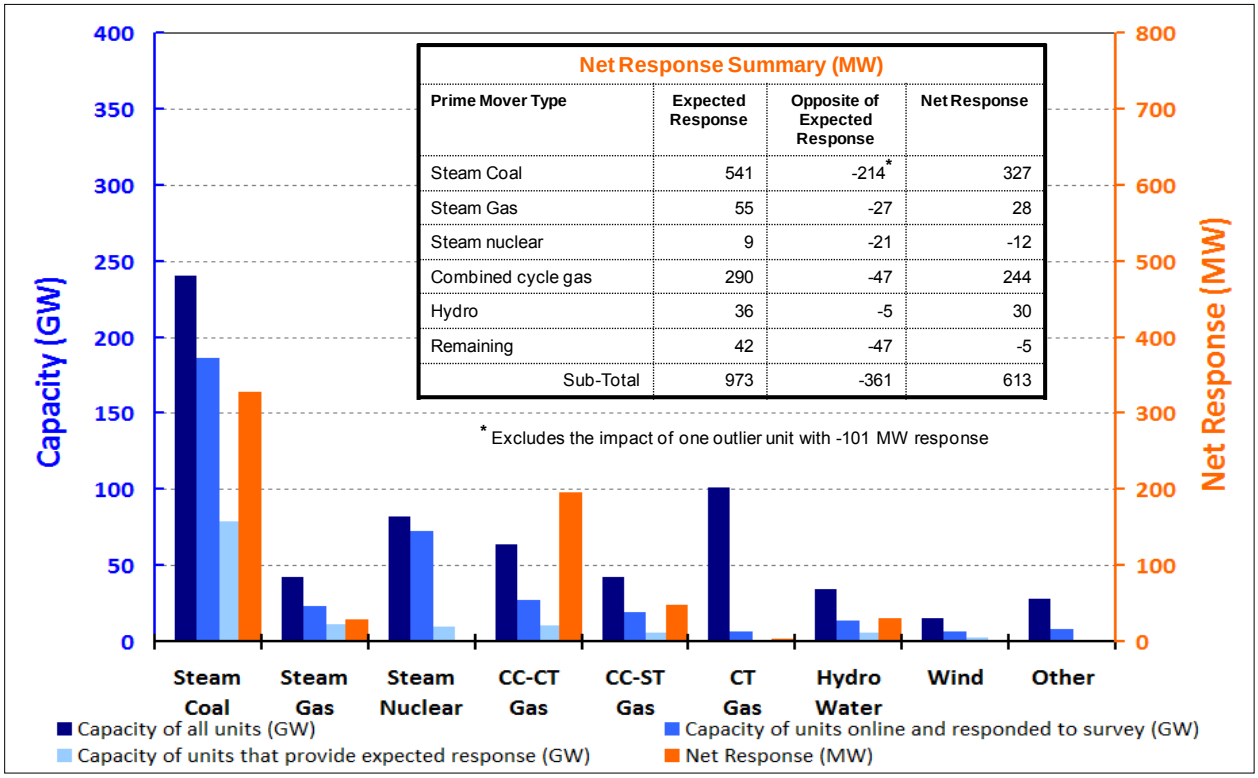

Figure 57 shows that for the Western Interconnection, total response in the expected direction was 1040 MW, while response in the direction opposite expectations was -180 MW, for a total net response of 860 MW. Hydro units, accounting for 727 MW of the net response, made the largest contribution. Hydro units made this contribution with a total on-line generating capacity of about 50 GW, of which about 19 GW of capacity provided response in the expected direction.

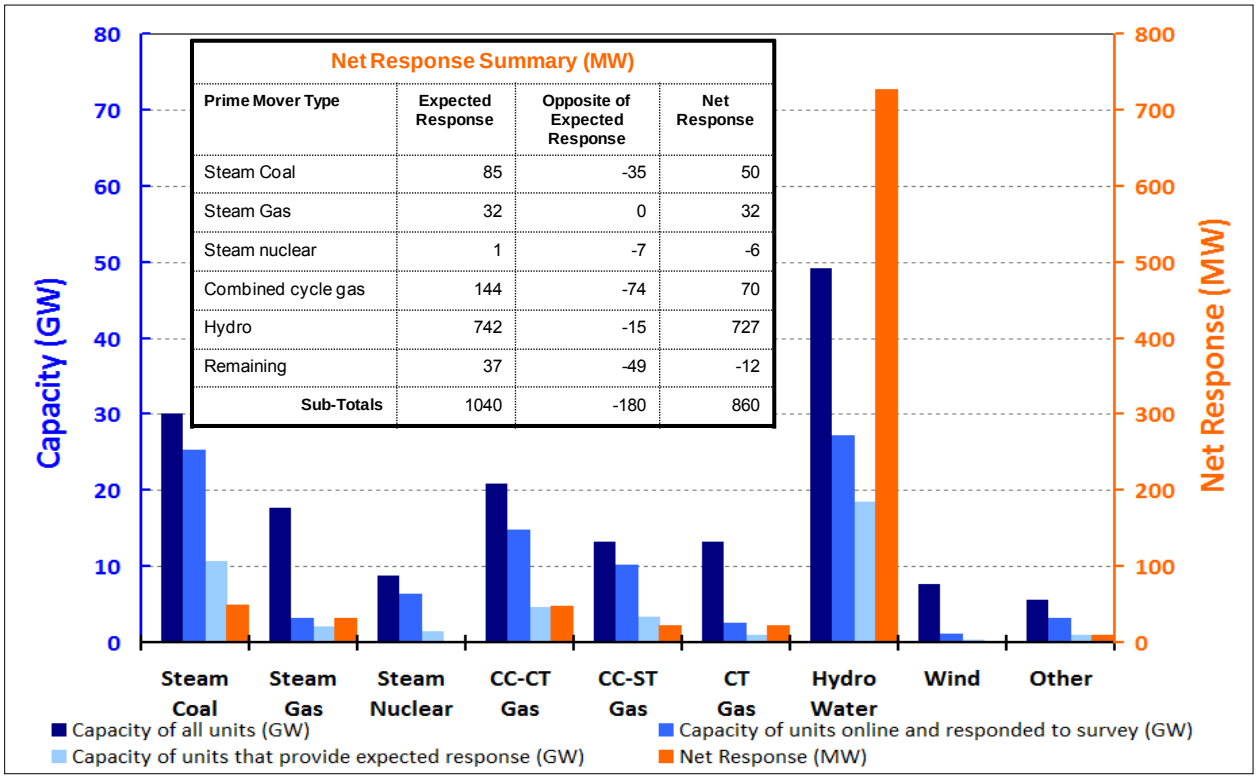
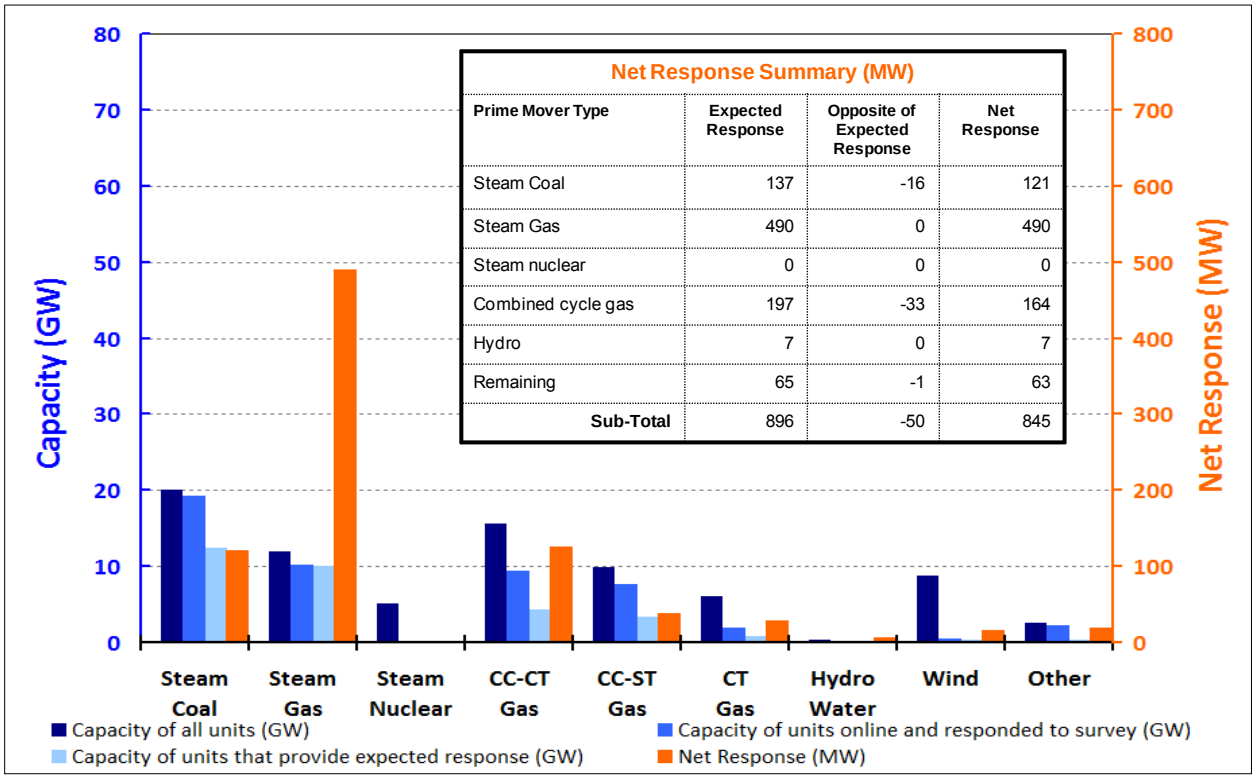
Figure 57: Western Interconnection Generator Governor Performance



Prime Mover Type	Expected Response	Opposite of Expected Response	Net Response
Steam Coal	85	-35	50
Steam Gas	32	0	32
Steam nuclear	1	-7	-6
Combined cycle gas	144	-74	70
Hydro	742	-15	727
Remaining	37	-49	-12
Sub-Totals	1040	-180	860

Figure 58 shows that for the ERCOT Interconnection, total response in the expected direction was 896 MW, while response in the direction opposite expectations was -50 MW, for a total net response of 845 MW. Steam gas units, accounting for 490 MW of the net response, made the largest contribution. Steam gas units made this contribution with a total on-line generating capacity of about 11 GW, of which ~10 GW of capacity provided response in the expected direction.

Figure 58: ERCOT Interconnection Generator Governor Performance



Net Response Summary (MW)

Prime Mover Type	Expected Response	Opposite of Expected Response	Net Response
Steam Coal	137	-16	121
Steam Gas	490	0	490
Steam nuclear	0	0	0
Combined cycle gas	197	-33	164
Hydro	7	0	7
Remaining	65	-1	63
Sub-Total	896	-50	845

Future Analysis Work Recommendations

Testing of Eastern Interconnection Maximum Allowable Frequency Deviations

The stability simulation testing of the Eastern Interconnection resource loss criteria used in the determination of the IFRO was limited to analysis using the generic governor stability case developed by the NERC Model Validation Working Group and the Eastern Interconnection Reliability Assessment Group (ERAG) Multi-Regional Modeling Working Group (MMWG) in December 2011 (based on the August 4, 2007 Eastern Interconnection Frequency Disturbance). Simulations using that stability simulation indicated a maximum sustainable generation loss of about 8,500 MW for the Eastern Interconnection. However, that simulation case was not for the light load conditions where system inertia and load response would be expected to be lower than in the generic case.

Recommendation – Dynamic simulation testing of the Western and ERCOT Resource Contingency Protection Criteria should be conducted as soon as possible.

Recommendation – When ERAG MMWG completes its review of turbine governor modeling, a new light-load case should be developed, and the resource loss criterion for the Eastern Interconnection's IFRO should be re-simulated.

Eastern Interconnection Inter-area Oscillations – Potential for Large Resource Losses

During the spring of 2012, a number of inter-area oscillations were observed between the upper Midwest and the New England/New Brunswick areas in the 0.25 Hz family. During one such event, a large generation outage in Georgia instigated that oscillation mode and was interpreted by the FNet frequency monitoring and event detection program as an 1,800 MW resource loss in the upper Midwest. Immediately, the FNet Oscillation Monitoring system detected the 0.025 Hz family oscillations between the upper Midwest and New England/New Brunswick. Investigation into the event showed that it occurred while the Dorsey – Forbes 500 kV transmission line was out of service for maintenance. During that line outage, the transfers on the Dorsey DC line from Northern Manitoba were significantly curtailed, and the oscillation of the Dorsey DC terminal capabilities for damping the 0.025 Hz oscillations were greatly reduced. This made the system more susceptible to such oscillations. In all instances, the energy magnitude under the oscillations was small, well-damped, and of little danger to the reliability of the Eastern Interconnection.

However, the instigation of those oscillations by a generator trip in Georgia seemed unlikely until reviewed in light of the inter-area oscillations detected following the South Florida disturbance of February 26, 2008. During that disturbance, a family of 0.22 Hz oscillations was detected between the Southeast and the upper Midwest. In both cases, the same generation

in the upper Midwest has a strong participation in both mode shapes, and since both oscillation modes are close in frequency, the 0.25 Hz family was easily perturbed by an instance of the 0.22 Hz mode oscillations caused by the Georgia generator tripping.

Recommendation – Eastern Interconnection inter-area oscillatory behavior should be further investigated by NERC, including during the testing of large resource loss analysis for IFRO validation.

Definitions used in Standard BAL-003-1

Frequency Response Measure (FRM)

The median of all the Frequency Response observations reported annually by Balancing Authorities or Frequency Response Sharing Groups for frequency events specified by the ERO. This will be calculated as MW/0.1Hz.

Frequency Response Obligation (FRO)

The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection. This will be calculated as MW/0.1Hz.

Frequency Bias Setting

A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's inverse Frequency Response contribution to the interconnection, and discourage response withdrawal through secondary control systems.

Frequency Response Sharing Group (FRSG)

Groups, whose members consist of two or more Balancing Authorities, that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.

Area Control Error (ACE)*: The instantaneous difference between a Balancing Authority's net actual and scheduled interchange, taking into account the effects of Frequency Bias and correction for meter error.

Arrested Frequency – Value C – Point C – Frequency Nadir: The point of maximum frequency excursion in the first swing of the frequency excursion between time zero (Point A) and time zero plus 20 seconds.

Arresting Period: The period of time from time zero (Point A) to the time of Point C.

Arresting Period Frequency Response: A combination of load damping and the initial Primary Control Response acting together to limit the duration and magnitude of frequency change during the Arresting Period.

Automatic Generation Control (AGC)*: Equipment that automatically adjusts generation in a Balancing Authority Area from a central location to maintain the Balancing Authority's

interchange schedule plus Frequency Bias. AGC may also accommodate automatic inadvertent payback and time error correction.

Balancing Authority (BA)*: The responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports interconnection frequency in real time.

Beta: The factor by which the frequency deviation is multiplied by in the ACE equation to adjust the ACE to protect a BA's Frequency Response.

Contingency Protection Criteria of an interconnection: The selected capacity contingency that an interconnection must withstand at all times without the activation of the first tier of UFLS.

Contingency Reserve*: The provision of capacity deployed by the Balancing Authority to meet the Disturbance Control Standard (DCS) and other NERC and Regional Reliability Organization contingency requirements.

Frequency [i]: The rate at which a repeating waveform repeats itself. Frequency is measured in cycles per second or in hertz (Hz). The symbol is "F."

Frequency Bias Setting: The term of the ACE equation that is multiplied by frequency deviation portion. This is a corrective term to offset the tie-line flow error caused by generation/load responding to a frequency deviation.

Frequency Deviation*: A change in interconnection frequency.

Frequency Response*: (Equipment) The ability of a system or elements of the system to react or respond to a change in system frequency. (System) The sum of the change in demand, plus the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 hertz (MW/0.1 Hz).

Frequency Responsive Reserve (a.k.a., dynamic headroom): The capacity of Governor Response and/or Frequency-Responsive Demand Response that will be deployed for any frequency excursion.

Frequency-Responsive Demand Response: Voluntary load shedding that complements governor response. This load reduction is typically triggered by relays that are activated by frequency.

Frequency Sensitive Load: Customer loads that vary directly with changes in frequency or would trip as a result of frequency deviations.

Governor response[§]: The control response of turbine-governors to sensing a change in speed of the turbine as frequency increases or declines, causing an adjustment to the energy input of the turbine's prime mover.

Headroom: The difference between the current operating point of a generator and its maximum operating capability.

Inertia[i]: The property of an object that resists changes to the motion of an object. For example, the inertia of a rotating object resists changes to the object's speed of rotation. The inertia of a rotating object is a function of its mass, diameter, and speed of rotation.

Load damping[¥]: The damping effect of the load to a change in frequency due to the physical aspects of the load such as the inertia of motors and the physical load to which they are connected.

Load following[i]: Commitment of energy based resources (generation or energy schedule) to match the forecast load level for a given period. This is a form of course control for moment-by-moment resource/load matching.

Non-spinning reserve*: 1. That generating reserve not connected to the system but capable of serving demand within a specified time. 2. Interruptible load that can be removed from the system in a specified time.

Off-line Reserve[§]: The off-line capability above firm system demand required to provide for regulation, load forecasting error, equipment forced and scheduled outages, and local area protection.

On-line Reserve[§]: The on-line capability above firm system demand required to provide for regulation, load forecasting error, equipment forced and scheduled outages, and local area protection. This can consist of spinning reserve and interruptible load that can act as a resource.

Operating Reserve*: That capability above firm system demand required to provide for regulation, load forecasting error, equipment forced and scheduled outages, and local area protection. It consists of spinning and non-spinning reserves.

Other On-line Reserves[§]: On-line Resources that can increase their output or connected loads that can decrease their consumption (curtailable loads) in time frames outside the continuum of regulating or spinning reserve (i.e. on four hours' notice).

Other Off-line Reserves[§]: Resources that can be brought to bear outside the continuum of non-spinning reserve (i.e., on four hours' notice).

Plant secondary control[@]: Secondary control refers to controls affected through commands to a turbine controller issued by external entities not necessarily working in concert with frequency management objectives. It is common for a modern power plant to have several distinct modes of secondary control implemented within the plant and to be able to accept secondary control inputs from sources external to the plant.

Primary Control Response Withdrawal: The withdrawal of previously delivered Primary Control Response, through plant secondary controls.

Primary Frequency Control Response: The power delivered to the interconnection in response to a frequency deviation through generator governor response, load response (typically from motors), demand response (designed to arrest frequency excursions), and other devices that provide an immediate response to frequency based on local (device-level) control systems, without human or remote intervention.

Primary Frequency Control Reserves: Frequency-responsive reserves that respond nearly instantaneously (starting in less than 1 second) to oppose any changes in power system frequency.

Quick Start Reserve: A form of non-spinning reserve that can be put on-line and the capacity that can be deployed in ten minutes.

Recovery Period: The period of time from when Secondary Control Response are deployed (typically about zero plus 53 seconds) to the time of the return of frequency to within pre-established ranges of reliable continuous operation.

Regulation[¥]: Controllable resources necessary to provide for the continuous balancing of resources (generation and interchange) with load and for maintaining scheduled interchange and interconnection scheduled frequency. Regulation is accomplished by committing on-line generation whose output is raised or lowered (predominantly through the use of automatic generating control equipment) as necessary to follow the moment-by-moment changes actual net interchange.

Regulating reserve*: An amount of reserve responsive to Automatic Generation Control, which is sufficient to provide a normal regulating margin.

Settling frequency[¥, #]: Refers to the third key event during a disturbance when the frequency stabilizes following a frequency excursion. Point B represents the interconnected system frequency at the point immediately after the frequency stabilizes due to governor action but before the contingent control area takes corrective AGC action.

Secondary Control Response: The power delivered by a Balancing Authority or Reserve Sharing Group in response to a frequency deviation through Secondary Control actions, such as manual or automated dispatch from a centralized control system. Secondary control actions are intended to restore Primary Control Response and restore frequency from the Arrested Frequency back to Scheduled Frequency, or maintain Scheduled Frequency.

Secondary Frequency Control: Actions provided by an individual BA or its Reserve Sharing Group intended to restore Primary Control Response and restore frequency from the Arrested Frequency back to Scheduled Frequency, or to maintain Scheduled Frequency deployed in the “minutes” time frame. Secondary Control comes from either manual or automated dispatch from a centralized control system. Secondary Control also includes initial reserve deployment for disturbances and maintains the minute-to-minute balance throughout the day and is used to restore frequency to normal following a disturbance and is provided by both spinning and non-spinning reserves.

Secondary Frequency Control Reserves: Frequency-responsive reserves that respond over slightly longer time frames (starting in 20-30 seconds). Following the sudden loss of generation, they assist in restoring frequency to the scheduled value after Primary Frequency Control Reserves have been deployed. They also safeguard Primary Frequency Control Reserves (so that primary reserves remain available to respond to these sudden events) by controlling frequency in response to slower imbalances that arise between electricity demand and generation such as the normal rise and fall of system load over the course of a day.

Spinning reserve*: Unloaded generation that is synchronized and ready to serve additional demand.

Tertiary frequency control[§]: Encompasses actions taken to get resources in place to handle current and future changes in load or contingencies. Reserve deployment and Reserve restoration following a disturbance is a common type of Tertiary frequency control.

Under-frequency load shedding[i]: The tripping of customer load based on magnitudes of system frequency. For example, a utility may dump 5% of their connected load if frequency falls below 59.3 Hz, dump an additional 10% if frequency falls below 58.9 Hz, and dump a final 10% if frequency falls below 58.5 Hz. These three steps of load shedding would form this utility's UFLS plan. The purpose of UFLS is a final effort (safety net) to arrest a frequency decline.

Appendix E – ALR1-12 Metric Event Selection Process

1. CERTS-EPG produces a monthly spreadsheet for four interconnections (Eastern Interconnection or EI, Western or WI, ERCOT Interconnection or TI, and Québec). The spreadsheet captures significant frequency events based on the Resources Subcommittee (RS) specified threshold. The Frequency Monitoring and Analysis tool (FMA) gathers and stores the raw data.
2. The spreadsheet is sent by CERTS-EPG to the Frequency Working Group (FWG) on the 15th of each month for the previous month's raw data.
3. The FNET application uses automatic e-mails to flag frequency deviations. Generation loss is estimated.
4. The actual generation loss for the FNET flagged frequency events is determined by the NERC Situation Awareness Coordinator from the Regional Entities and sent to the FWG.
5. The FWG members validate the data and add the actual generation loss values into the spreadsheet.
6. FWG sends the validated monthly sheet to the Resource Subcommittee (RS) and the Performance Analysis Subcommittee (PAS) on the 30th of each month for the previous month's raw data.
7. NERC staff will update the candidate event list on the NERC website that will be used to support the standard. The final official event list for a year will be identified as a subset of the posted candidate list.
8. PAS publishes the quarterly Frequency Response metric data on NERC's Reliability Indicators webpage. The initial trending will be based on annual median/mean and rolling 12 month values.

Background Information

The frequency delta thresholds recommended by RS for the Eastern, Western, ERCOT and Québec Interconnections are shown in Table E1.

Table E1: Frequency delta thresholds recommended by RS

Interconnections	Frequency Delta for events captured in (mHz)	Frequency Delta for Significant events that have a higher Delta	Time Window (Seconds)
Eastern	24	36	15
Western	40	70	15
ERCOT	45	90	15
Québec	140	200	15

The raw statistics for events in 2008, 2009, 2010 and the first half of 2011 are listed in Table E2 below. This was sent by CERTS-EPG to the FWG on August 31, 2011.

Table E2: Raw Statistics for frequency events from 2008 to July 2011

Interconnection	Eastern	Western	ERCOT	Québec
2008	195	102	26	No Data
2009	78	72	85	No Data
2010	132	85	122	No Data
2011 (until July)	70	37	61	159

The statistics for TI from 2008 to 2011 were validated and modified by the FWG. Table E3 shows the statistics for TI that were sent by the FWG to the RS on September 02, 2011.

Table E3: Validated Statistics for TI frequency events from 2008 to July 2011

Interconnections	TI
2008	8
2009	51
2010	67
2011 (until July)	40

The FWG Lead members who will validate the data and add the actual generation loss values into the spreadsheet for the four interconnections are listed in Table E4.

Table E4: Lead members for the four interconnections

Terry L. Bilke	Eastern Interconnection
Don E. Badley	Western Interconnection
Sydney L. Niemeyer	ERCOT Interconnection
Michael Potishnak	Québec Interconnection

In July 2011, CERTS-EPG produced the first of the monthly reports for the FWG. July 2011 has 22 frequency events and a summary is shown in Table E5.

Table E5: Summary of the 1st monthly report produced by CERTS-EPG for the FWG in July 2011

Appendix F – Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard (BAL-003-1)

Event Selection Process

This procedure outlines the ERO process for supporting the Frequency Response Standard (FRS). A procedure revision request may be submitted to the ERO for consideration. The revision request must provide a technical justification for the suggested modification. The ERO will post the suggested modification for a 45-day comment period and discuss the revision request in a public meeting. The ERO will make a recommendation to the NERC BOT, which may adopt the revision request, adopt it with modifications, or reject it. Any approved revision to this procedure will be filed with FERC for informational purposes.

Event Selection Objectives

The goals of this procedure are to outline a transparent, repeatable process to annually identify a list of frequency events to be used by Balancing Authorities (BA) to calculate their Frequency Response to determine:

- whether the BA met its Frequency Response Obligation; and
- an appropriate fixed bias setting.

Event Selection Criteria

1. The ERO will use the following criteria to select FRS frequency excursion events for analysis. The events that best fit the criteria will be used to support the FRS. The evaluation period for performing the annual Frequency Bias Setting and the Frequency Response Measure (FRM) calculation is December 1 of the prior year through November 30 of the current year.
2. The ERO will identify 20–35 frequency excursion events in each interconnection for calculating the Frequency Bias Setting and the FRM. If the ERO cannot identify 20 frequency excursion events in a 12-month evaluation period satisfying the criteria below, then similar acceptable events from the subsequent year's evaluation period will be included with the data set by the ERO for determining FRS compliance.
3. The ERO will use three criteria to determine if an acceptable frequency excursion event for the FRM has occurred:
    a. The change in frequency as defined by the difference from the A Value to Point C and the arrested frequency Point C exceeds the excursion threshold values specified for the interconnection in Table F1 below.
        i. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline.

ii. Point C is the arrested value of frequency observed within 12 seconds following the start of the excursion.

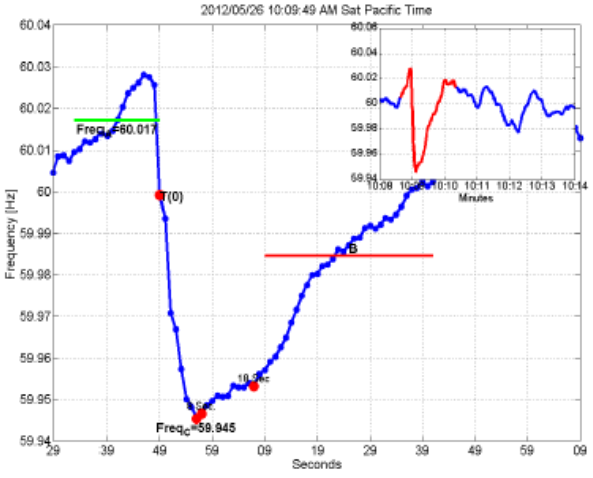
Table F1: Interconnection Frequency Excursion Threshold Values (Hz)

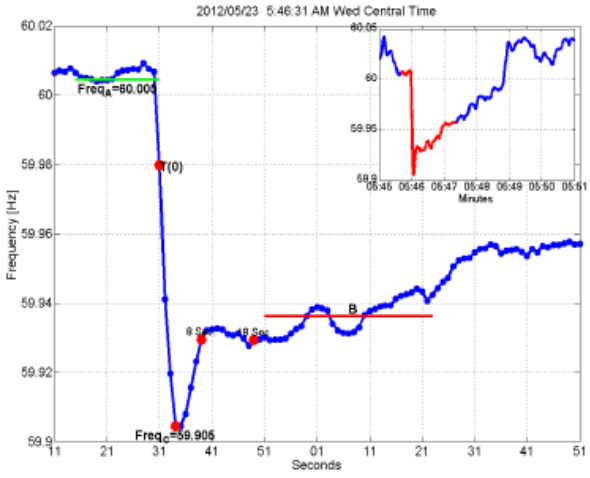
Interconnection	A Value to Pt C	Point C (Low)	Point C (High)
Eastern	0.04	< 59.96	> 60.04
Western	0.07	< 59.95	> 60.05
ERCOT	0.15	< 59.90	> 60.10
Québec	0.30	< 59.85	> 60.15

b. The time from the start of the rapid change in frequency until the point at which frequency has stabilized within a narrow range should be less than 18 seconds.

c. If any data point in the B Value average recovers to the A Value, the event will not be included.

4. Pre-disturbance frequency should be relatively steady and near 60.000 Hz for the A Value. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline. For example, given the choice of the two events below, the one on the right is preferred as the pre-disturbance frequency is stable and also closer to 60 Hz.





5. Excursions that include two or more events that do not stabilize within 18 seconds will not be considered.

6. Frequency excursion events occurring during periods when large interchange schedule ramping or load change is happening, and frequency excursion events occurring within 5

minutes of the top of the hour, will be excluded from consideration if other acceptable frequency excursion events from the same quarter are available.

7. The ERO will select the largest (A Value to Point C) two or three frequency excursion events occurring each month. If there are not two frequency excursion events that satisfy the selection criteria in a month, then other frequency excursion events should be picked in the following order of priority:
    1) from the same event quarter of the year
    2) from an adjacent month
    3) from a similar load season in the year (shoulder vs. summer/winter)
    4) the largest unused event

As noted earlier, if a total of 20 events are not available in an evaluation year, then similar acceptable events from the next year's evaluation period will be included with the data set by the ERO for determining FRO compliance. The first year's small set of data will be reported and used for Bias Setting purposes, but compliance evaluation on the FRO will be done using a 24 month data set.

To assist Balancing Authority preparation for complying with this standard, the ERO will provide quarterly posting of candidate frequency excursion events for the current year FRM calculation. The ERO will post the final list of frequency excursion events used for standard compliance as specified in Attachment A of BAL-003-1. The following is a general description of the process that the ERO will use to ensure that BAs can evaluate events during the year in order to monitor their performance throughout the year.

Monthly

Candidate events will be initially screened by the "Frequency Event Detection Methodology" shown on the following link located on the NERC Resources Subcommittee area of the NERC website:
http://www.nerc.com/docs/oc/rs/Frequency_Event_Detection_Methodology_and_Criteria_Oct_2011.pdf.

Each month's list will be posted by the end of the following month on the NERC website, http://www.nerc.com/filez/rs.html and listed under "Candidate Frequency Events."

Quarterly

The monthly event lists will be reviewed quarterly with the quarters defined as:

- December through February
- March through May
- June through August
- September through November

Based on criteria established in the "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard," events will be selected to populate the FRS Form 1 for each interconnection. Each interconnection's Form 1 will be posted on the NERC website, in the Resources Subcommittee area under the title "Frequency Response Standard Resources." The updated Form 1 documents will be posted at the end of each quarter listed above after a review by the NERC RS Frequency Working Group. While the events on this list are expected to be final, as outlined in the selection criteria, additional events may be considered, if the number of events throughout the year do not create a list of at least 20 events. It is intended that this quarterly posting of updates to the FRS Form 1 would allow BAs to evaluate the events throughout the year, lessening the burden when the yearly posting is made.

Annually

The final FRS Form 1 for each interconnection, which will contain the events from all four quarters listed above, will be posted as specified in Attachment A. Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO as specified in Attachment A using the final FRS Form 1. The ERO will error check and use the FRS Form 1 data to calculate CPS limits and FROs for the upcoming year.

Once the data listed above is fully reviewed, the ERO may adjust the implementation specified in Attachment A for changing the Frequency Bias Settings and CPS limits. This allows flexibility in when each BA implements its settings.

Appendix G – Statistical Analysis of Frequency Response (Eastern Interconnection)

Statistical Analysis of Frequency Response

Eastern Interconnection August 7, 2012

Introduction

An interconnected electric power system is a complex system that must be operated within a safe frequency range to reliably maintain the instantaneous balance between generation and load, and is directly reflected in the frequency of the interconnection. Frequency Response is one measurement of how a power system has performed in response to the sudden loss of generation or load. This white paper analyzes the Frequency Response data for the Eastern Interconnection using statistical methods to study the probability distribution of the Frequency Response and its changes from year-to-year, as well as construct a set of variables that strongly influence Frequency Response.

Objectives and Method

The main goals of the statistical analysis of the Frequency Response data for the Eastern Interconnection are to study the:

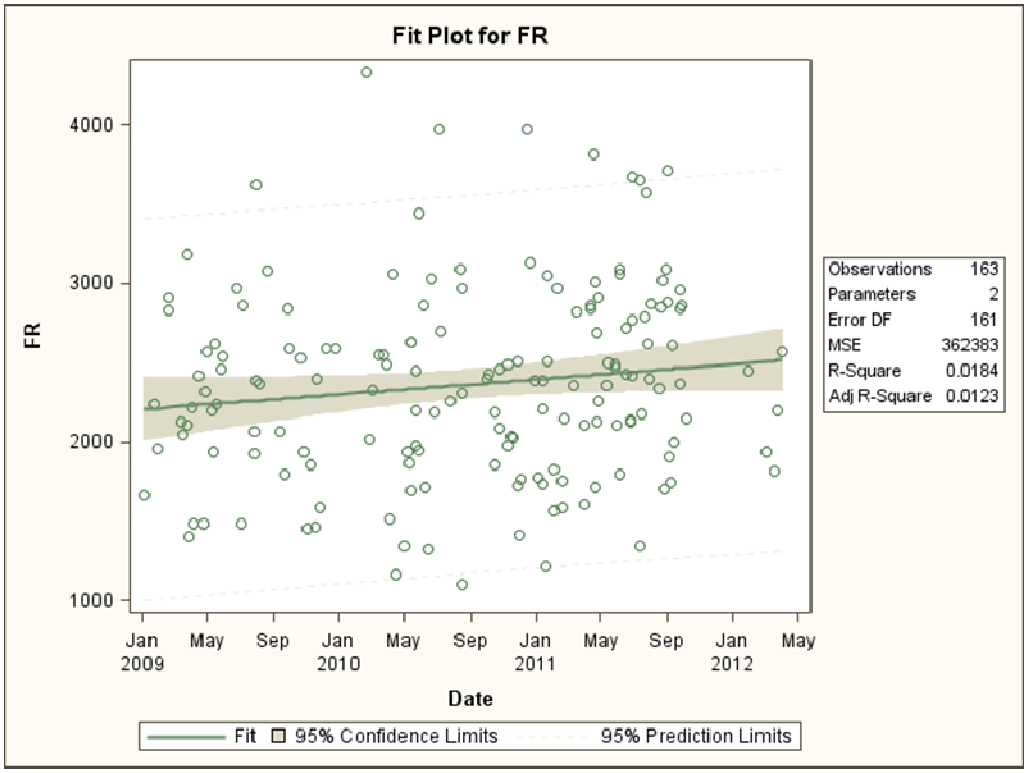
1. time trend of Frequency Response by selecting an appropriate model describing the relationship between a point in time when an event happens and the absolute value of Frequency Response for this event, and to use this model for Frequency Response forecasting with a given confidence level;
2. probability distribution of the Frequency Response and its changes over the years;
3. seasonal changes in Frequency Response distribution and correlation between Frequency Response value and season when the event happened (summer/non-summer);
4. impact of pre-disturbance frequency on Frequency Response;
5. impact of on-peak/off-peak hours on Frequency Response;
6. impact of interconnection load on Frequency Response; and
7. hierarchy of these explanatory factors of Frequency Response.

The analysis uses the Frequency Response dataset for the Eastern Interconnection for the calendar years 2009-2011 and the first three months of 2012. The size of this dataset is 163 frequency events (with 44 observations for the year of 2009, 49 for 2010, 65 for 2011, and 5 for 2012). Since interconnection load data are not yet available for 2012, the part of the study involving interconnection load deals with the 158 Frequency Response events occurred in 2009-2011. For purposes of this whitepaper, Frequency Response pertains to the absolute value of Frequency Response.

Key Findings

1. A linear regression equation with the parameters defined in the Appendix of this whitepaper is an adequate statistical model to describe a relationship between time (predictor) and Frequency Response (response variable). The graph of the linear regression line and Frequency Response scatter plot is given in Figure G1. For the dataset, the regression line has a small positive slope estimate, meaning that the Frequency Response variable has a slowly increasing general trend in time. The value of the slope estimate is 0.00000303805 (the time unit is a second). This means that, on average, Frequency Response increases daily by 0.26 MW/0.1Hz, monthly by 7.87 MW/0.1 Hz, and annually by 95.81 MW/ 0.1Hz (for a month with 30 days , and a year with 365 days). A 90% confidence interval for slope, CI=[-0.00000041605, 0.00000649214], has a negative left-end point (the same is true for a 95% CI and a 99% CI). With new data available the trend line can (a) increase its positive slope, (b) change the positive slope to a slight negative one, or (c) become essentially flat that will correspond to an absence of a correlation between time and Frequency Response.

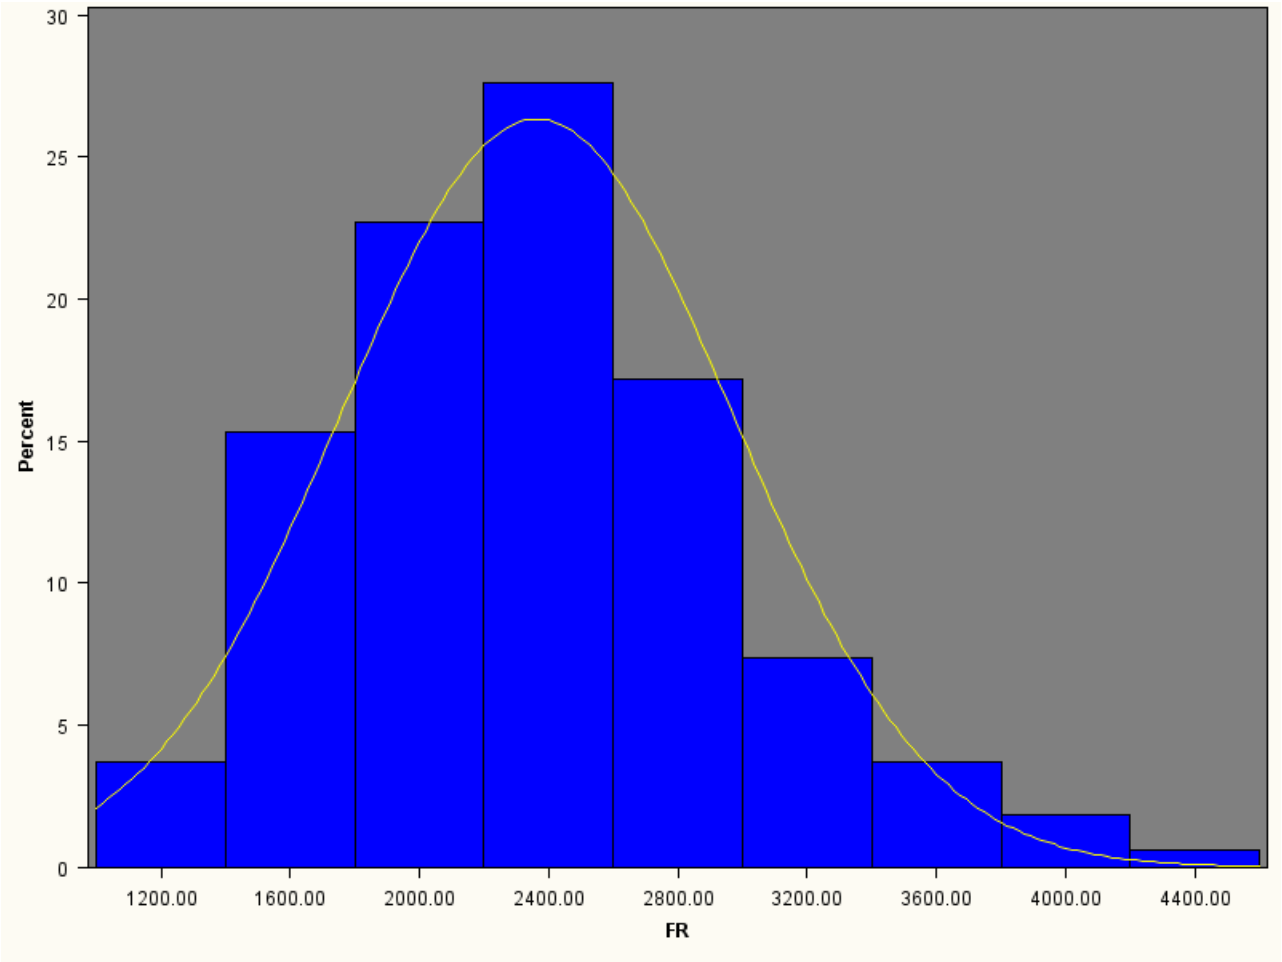
Figure G1: Frequency Response Scatter Plot



2. The probability distribution of the whole Frequency Response dataset is approximately normal with the expected Frequency Response of 2363 MW/0.1 Hz and the standard deviation of 605.7 MW/0.1 Hz as shown in Figure G2. The comparative statistical analysis for every pair of years shows that the changes in the 2010 data versus the 2009 data (and in the 2011 data versus the 2010 data) are not statistically significant enough to lead to the conclusion that the mean value of Frequency Response for any two consecutive years changes. However, the data for 2009 and 2011 differ at the level that results in accepting

the hypothesis that the expected value of Frequency Response for 2011 is greater than for 2009.

Figure G2: Probability Distribution of the Entire Frequency Response Data Set



3. A season (summer/non-summer) is a significant contributor to the variability of Frequency Response. There is a positive correlation of 0.24 between the indicator function for summer (defined as 1 for events that occur in June–August and 0 otherwise) and Frequency Response: summer events have a statistically significantly greater expected Frequency Response (the sample mean equals to 2598MW/0.1 Hz) than non-summer events (the mean equals to 2271 MW/0.1 Hz).

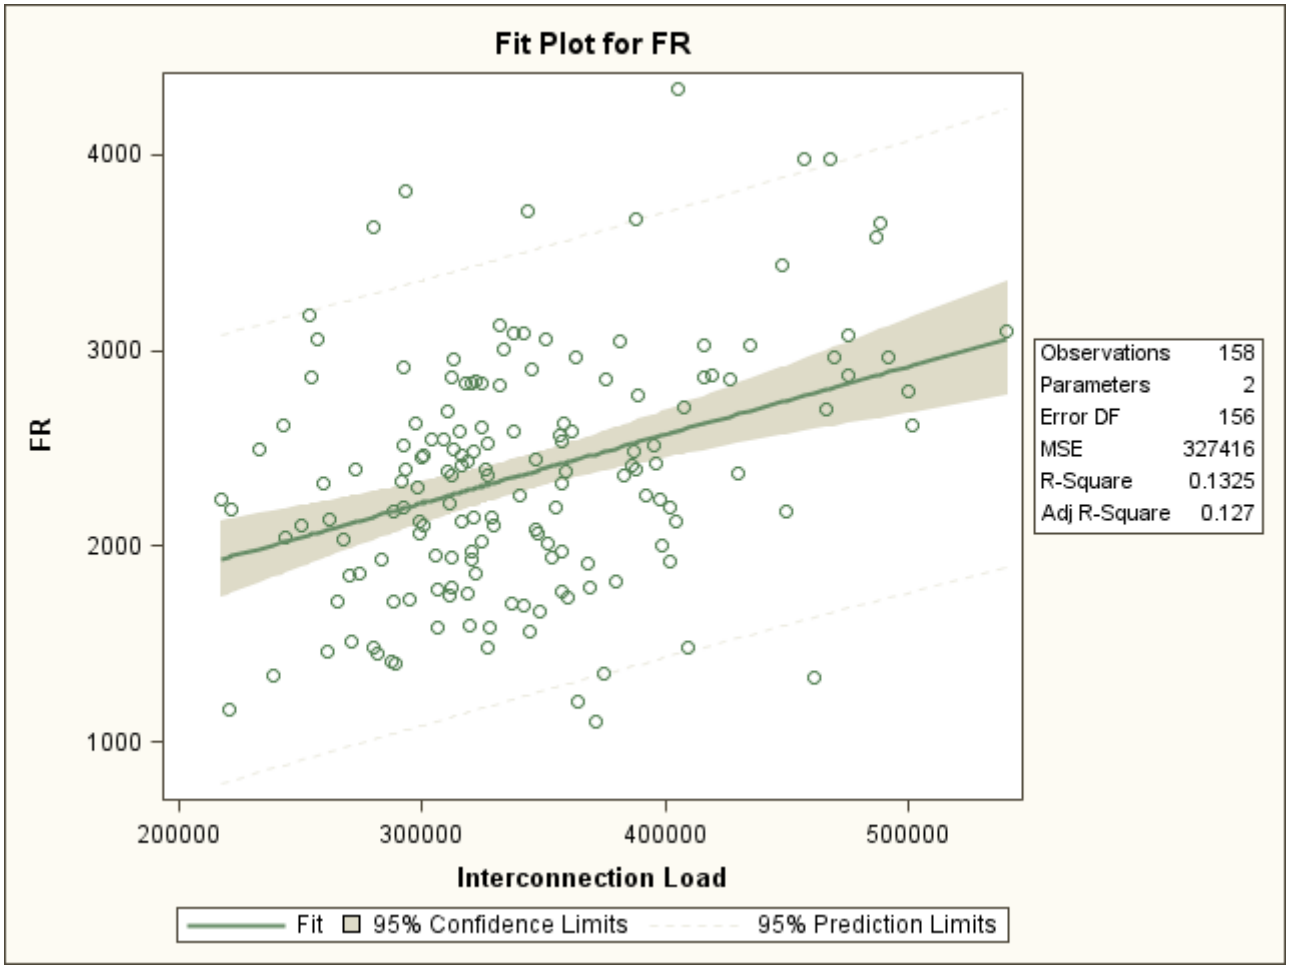
4. Pre-disturbance (average) frequency (A) is another significant contributor to the variability of Frequency Response. There is a negative correlation of -0.27 between the indicator function of A>60 Hz and Frequency Response: the events with A>60 Hz have a statistically significantly smaller expected Frequency Response (the sample mean equals to 2188 MW/0.1 Hz) than the events with A≤60 Hz (the mean equals to 2513 MW/0.1 Hz).

5. According the NERC definition, for Eastern Interconnection on-peak hours are designated as follows: Monday to Saturday hours from 0700 to 2200 (Central Time) excluding six holidays (New Year's Day, Memorial Day, Independence Day, Labor Day, Thanksgiving Day and Christmas Day). It turns out that on-peak/off-peak variable is not a statistically significant

contributor to the variability of Frequency Response. There is a positive correlation of 0.06 between the indicator function of on-peak hours and Frequency Response; however, difference in average Frequency Response between on-peak events and off-peak events is not statistically significant and could occur by chance (P-value is 0.49).

6. There is a strong positive correlation of 0.364 between interconnection load and Frequency Response for the 2009-2011 events; this correlation indicates to a statistically significant linear relationship between interconnection load (predictor) and Frequency Response (response variable). The graph of the linear regression line and Frequency Response scatter plot is given in Figure G3. For the dataset, the regression line has a positive slope estimate of 0.00349; thus, the Frequency Response variable increases when interconnection load grows. On average, when interconnection load changes by 1000 MW, Frequency Response changes by 3.5 MW/0.1Hz.

Figure G3: Linear Regression for Frequency Response and Interconnection Load



7. For the 2009–2011 dataset, five variables (time, summer, high pre-disturbance frequency, on-peak/off-peak hour, interconnection load) have been involved in the statistical analysis of Frequency Response. Four of these (time, summer, on-peak hours, and interconnection load) have a positive correlation with Frequency Response (0.16, 0.24, 0.06, and 0.36,

respectively), and the high pre-disturbance frequency has a negative correlation with Frequency Response (-0.26). The corresponding coefficients of determination R^2 are 2.6%, 5.8%, 0.4%, 13.3% and 6.9%. These values indicate that about 2.6% in variability of Frequency Response can be explained by the changes in time, about 5.8% of Frequency Response variability is seasonal, 0.4% is due to on-peak/off-peak changes, 13.3% is the effect of the interconnection load variability, and about 6.9% can be accounted for by a high pre-disturbance frequency. However, the correlation between Frequency Response and On-Peak hours is not statistically significant and with the probability about 0.44 occurred by mere chance (the same holds true for the corresponding R^2). Therefore, out of the five parameters, interconnection load has the biggest impact on Frequency Response followed by the indicator of high pre-disturbance frequency. A multivariate regression with interconnection load and A>60 as the explanatory variables for Frequency Response yields a linear model with the best fit (it has the smallest mean square error among the linear models with any other set of explanatory variables selected from the five studied). Still, together these two factors can account for about 20% in variability of Frequency Response. Therefore, there are other parameters that affect Frequency Response, have a low correlation with those studied, together account for a remaining share in Frequency Response variability, and minimize a random error variance. Note that interconnection load is positively correlated with summer (0.55), on-peak hours (0.45), and Date (0.20) but uncorrelated with A>60 (P-value of the test on zero correlation is 0.90).

Explanatory Variables for EI Frequency Response (2009-2011)

Variable X	Sample Correlation (X,FR)	P-value	Linear Regression Statistically Significant?	Coefficient of Determination R^2 (Single Regression)
Interconnection Load	0.36	<0.0001	Yes	13.3%
A>60	-0.26	0.0008	Yes	6.9%
Summer	0.24	0.0023	Yes	5.8%
Date	0.16	0.044	Yes	2.6%
On-Peak Hours	0.06	0.438	No	N/A

Appendix – Background Materials

Frequency Response is a metric used to track and monitor Interconnection Frequency Response. Frequency Response[2] is a measure of an interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load. It is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The metric measures the average Frequency Response for all events where frequency drops more than the interconnection's defined threshold as shown in Table 1.

Frequency Response Definition

For a given interconnection, Frequency Response is defined as the sum of the change in demand, plus the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 hertz (MW/0.1 Hz).

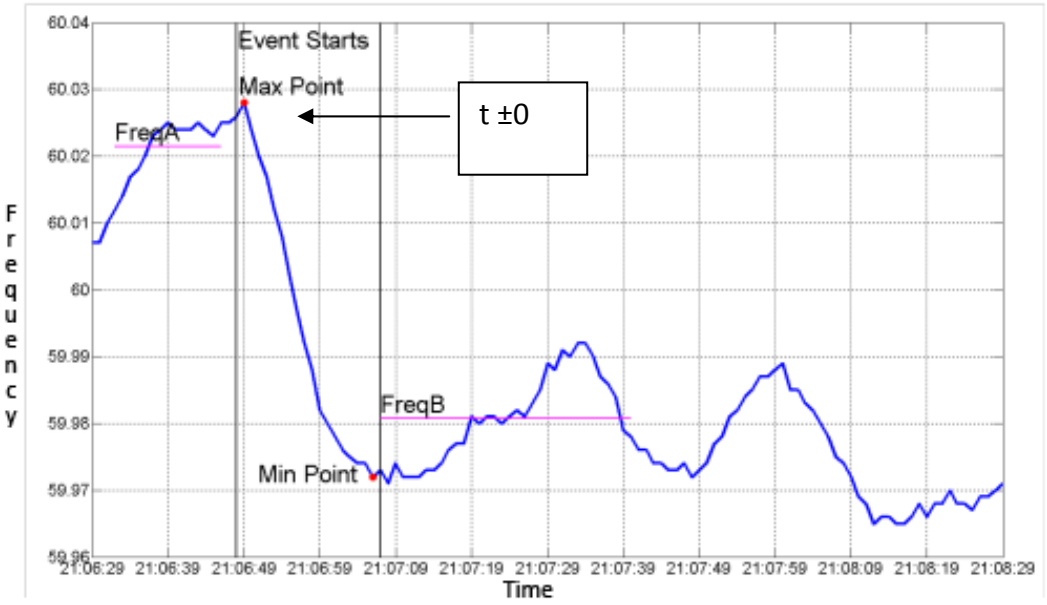
Table 1: Frequency Event Triggers for Data Collection

Interconnection	ΔFrequency (mHz)	MW Loss Threshold	Rolling Windows (seconds)
Eastern	40	800	15
Western	70	700	15
ERCOT	90	450	15
Québec	300	450	15

The change in frequency is the difference between pre-disturbance frequencies A and setting frequency B. Figure 3 shows the criteria for calculating average values A and B. The event starts at time t ±0. Value A is the average from t -16 to t -2 and Value B is the average from t +20 to t +52. These lengths of time used to calculate these values accounts for the variability in Supervisory Control and Data Acquisition (SCADA) scan rates that vary from 2 to 6 seconds in the multiple-Balancing Authority interconnections. For Balancing Authority SCADA data, t ±0 represents the first scan of data that is part of the disturbance. Value A is the average of all SCADA scans between 2 and 16 seconds before t ±0. Value B is the average of all SCADA scans between 20 and 52 seconds after t ±0.

[2] Frequency Response is in fact a negative value. However to reduce confusion for the reader, Frequency Response is expressed in this report as positive values (the absolute value of the actual calculated value).

Figure 3: Criteria for Calculating Value A and Value B



The actual MW loss for the flagged frequency events is determined jointly by NERC and Regional Entity situation awareness staff. Both the change in frequency and the MW loss determine whether the event qualifies for further consideration in the monthly frequency event candidate list.

Statistical Analysis

Linear Regression for Time Trend

Assumptions: Frequency Response and time are related by the following regression equation:

$$FR = A * Time + B + \varepsilon$$

Where:

- $Time$ variable represents a time (year, month, day, hour, minute, second) when a Frequency Response event happened. For each event the Frequency Response is calculated and recorded. This record represents an observation from the dataset. Time is an explanatory variable (predictor, regressor) of the linear regression;
- FR is the Frequency Response value measured in MW/0.1 Hz (response variable of the model);
- A is a slope of the regression line;
- B is an intercept of the regression line; and
- ε is a random error which has a centered normal distribution with variance σ^2.

A SAS program for the linear regression analysis yields the following results shown in figure G3.

(a) The equation of the regression line derived by the least squares method is $y = 0.00000304x - 2493.41315$ with $x = Time(\text{sec})$ elapsed between midnight of January 1, 1960 (the time origin for the date format in SAS) and the time of a FR event;
(b) Estimate for the variance σ^2 of the random error ε is 362,383 and for the standard deviation of ε is 601.98255;
(c) Statistical test for significance of the regression (based on the analysis of variance approach) is an important part of assessing the adequacy of the linear regression model for time and FR variables. The procedure tests a null-hypothesis that the slope A = 0 versus an alternative hypothesis that it is not 0. Sample value of F-statistic, 3.0170, has P-value of 0.0843 implying that the null hypothesis should be rejected (and the alternative hypothesis accepted) at any significance level above 0.0843. Therefore, the data are statistically significant to support a hypothesis about a linear relationship between time and Frequency Response assuming that the 8.43% significance level (i.e., the probability to reject the null hypothesis when it is true) is appropriate for the model selection. Alternatively, the hypothesis about the correlation coefficient ρ(time, FR) can be tested (with the null hypothesis ρ=0). These tests are equivalent and result in the same P-values for their test statistics.

Another important part of the verification of the linear regression model is testing the assumptions on the random error ε. Student's t-test on location and goodness-of-fit test for normality both result in acceptance the corresponding null-hypothesis (with P-values of 1.0000 and 0.881, respectively).

The linear regression equation with the parameters defined above is an adequate statistical model to describe the relationship between variables time of a FR event and Frequency Response value for this event. For the dataset, the regression line has a small positive slope estimate, meaning that Frequency Response variable has a slowly increasing general trend in time. However, the value of this slope estimate is very small, and confidence intervals for slope at 90%, 95% and 99% levels all have a negative left-end point. By using T-distribution for the slope estimator, we estimate that the probability that the slope of the regression is negative is below 5%.

The coefficient of determination R^2 for the linear regression model equals to 0.0184. This small value indicates very low degree of dependence of Frequency Response on time variable. Essentially, the linear regression model connecting FR and time accounts for 1.8% of variability in the Frequency Response data.

The random error ε has a large estimated variance that makes the "error" term of the linear regression equation a major component of the Frequency Response value. Our next goal is to consider the Frequency Response data as observations of a random variable independent of time and to study properties of its distribution.

Distribution of Frequency Response

Goodness-of-Fit test for normality of the distribution of the Frequency Response data results in acceptance on the null hypothesis at a significance level below 0.177 (including the standard levels of 1%, 5% and 10%). The sample estimate for the expected Frequency Response equals to 2363 MW/0.1 Hz and the sample standard deviation is 605.7 MW/0.1 Hz.

Since for each full year (2009, 2010, and 2011) the sample size of the Frequency Response data exceeds 40, we ran a large-sample test for the difference in the mean Frequency Response for 2009 versus 2010, 2010 versus 2011, and 2009 versus 2011. The null hypothesis that the difference is zero is accepted when the 2009 data are compared to the 2010 data, and when the 2010 data are compared to the 2011 data at any standard significance level (P-values of the two-sided tests are 0.54 and 0.28, respectively). For the 2009 versus 2011 comparison, the test result is not that conclusive (its P-value equals to 0.03 and, therefore, the null hypothesis should be rejected at the 5% and 10% significance levels but is accepted at the 1% level if tested versus an alternative hypothesis that the 2011 mean value is greater than the 2009 mean value).

Seasonal Variability of Frequency Response

Let a function summer be defined as follows: it equals to 1 for Frequency Response events that occur in June-August and 0 otherwise. The FR dataset is therefore divided in two subsets: the Frequency Response data for summer events and non-summer events, respectively. Summer Frequency Response set has 46 observations and non-summer set has 117 observations. The sample mean and the sample variance for the first dataset are 2597.7 MW/0.1 Hz and 675.5 MW/0.1 Hz, respectively. The sample mean and the sample variance for the second dataset are 2270.9 MW/0.1 Hz and 552.2 MW/0.1 Hz. A large-sample test for the difference in the mean Frequency Response for these distributions results in rejection of the null hypothesis that the difference is zero and acceptance of an alternative hypothesis that the expected Frequency Response for summer events is greater than for other events (P-value of the one-sided z-test is 0.0018).

Variables summer and Frequency Response are positively correlated (with the correlation equal to 0.24351), and the coefficient of determination R^2 of the linear regression model is 0.0593. The null hypothesis about zero correlation (no linear relationship between FR and summer) should be rejected (P-value is 0.0017). This analysis indicates that seasonality is a significant factor affecting Frequency Response: almost 6% of its variability is the seasonal variability.

Impact of Pre-Disturbance Frequency

Let a function high pre-disturbance frequency be defined as follows: it equals to 1 for Frequency Response events with A>60 Hz and 0 otherwise. The FR dataset is therefore divided in two subsets: the Frequency Response data for events with A>60 Hz and events with A≤60 Hz, respectively. High pre-disturbance frequency set has 75 observations and its complement has 88 observations. The sample mean and the sample variance for the first dataset are 2187.6 MW/0.1 Hz and 531.5 MW/0.1 Hz, respectively. The sample mean and the sample variance for the second dataset are 2512.8 MW/0.1 Hz and 627.4 MW/0.1 Hz. A large-sample test for the difference in the mean Frequency Response for these distributions results in rejection of the null hypothesis that the difference is zero and acceptance of an alternative hypothesis that the

expected Frequency Response for events with A>60 Hz is smaller than for other events (P-value of the one-sided z-test is 0.0002).

Variables high pre-disturbance frequency and Frequency Response are negatively correlated (with the correlation equal to -0.26844), and the coefficient of determination R^2 of the linear regression model is 0.0721. The null hypothesis about zero correlation (no linear relationship between FR and high pre-disturbance frequency) should be rejected (P-value is 0.0005). This analysis indicates that the high pre-disturbance frequency is a factor that accounts for 7.2% of the Frequency Response variability. In fact, out of the four variables involved in this study (time, summer, high pre-disturbance frequency, on-peak/off-peak hours), it is the biggest contributor to the variability of Frequency Response.

Impact of On-Peak/Off-Peak hours

Let a function on-peak hour be defined as follows: it equals to 1 for Frequency Response events occurred during an on-peak hour and 0 otherwise. The FR dataset is therefore divided in two subsets: the Frequency Response data for on-peak hours and off-peak hours, respectively. On-peak set contains 108 observations, and off-peak set has 55 observations. The sample mean and the sample variance for the first dataset are 2386.9 MW/0.1 Hz and 602.9 MW/0.1 Hz, respectively. The sample mean and the sample variance for the second dataset are 2316.6 MW/0.1 Hz and 614.1 MW/0.1 Hz. A large-sample test for the difference in the expected Frequency Response for these distributions results in acceptance of the null hypothesis that the difference is zero and rejection of an alternative hypothesis that the expected Frequency Responses for on-peak events and off-peak events are different (P-value of the two-sided z-test is 0.49).

Variables on-peak hour and Frequency Response are positively correlated (with the correlation equal to 0.005505), and the coefficient of determination R^2 of the linear regression model is 0.0030. However, the correlation is not statistically significant since the null hypothesis about zero correlation (no linear relationship between FR and on-peak hour) should be accepted (P-value is 0.4852). The same is true for the coefficient of determination: there is a high probability that on-peak hours have no explanatory power in the Frequency Response variability. Out of the four variables involved in this study (time, summer, high pre-disturbance frequency, on-peak/off-peak hours), it is the only factor with no statistically significant impact on Frequency Response.

Linear Model that relates Frequency Response to Interconnection Load

Assumptions: Frequency Response and interconnection load are related by the following regression equation:

$$FR = C * IL + D + \varepsilon$$

Where:

- IL is the value of interconnection load (in MW) for a Frequency Response event.
- FR is the Frequency Response value measured in MW/0.1 Hz (response variable of the model);

- C is a slope of the regression line;
- D is an intercept of the regression line; and
- ε is a random error which has a zero mean and variance of σ^2.

A SAS program for the linear regression analysis yields the following results shown in figure G3.:

(a) The equation of the regression line derived by the least squares method is

$$y = 0.00349x + 1174.09949;$$

(b) Estimate for the variance σ^2 of the random error ε is 327,416 and for the standard deviation of ε is 572.2; and

(c) Statistical test for significance of the regression (based on the analysis of variance approach) is an important part of assessing the adequacy of the linear regression model for interconnection load and FR variables. The procedure tests a null-hypothesis that the slope $C = 0$ versus an alternative hypothesis that it is not 0. Sample value of F-statistic, 23.83, has P-value of 0.0001 implying that the null hypothesis should be rejected (and the alternative hypothesis accepted) at any significance level above 0.0001. Therefore, the data are statistically significant to support a hypothesis about linear relationship between interconnection load and Frequency Response. Alternatively, the hypothesis about the correlation coefficient ρ between interconnection load and Frequency Response can tested (with the null hypothesis ρ=0). These tests are equivalent and result in the same P-values for their test statistics.

The coefficient of determination R^2 for the linear regression model equals to 0.1325. This value indicates high degree of dependence of Frequency Response on interconnection load. Essentially, the linear regression model connecting FR and interconnection load accounts for about 13.3% of variability in the Frequency Response data.

Multiple Linear Regression

A statistically significant linear regression model connects interconnection load and high pre-disturbance frequency (regressors) and Frequency Response (response variable). The estimates of the linear regression coefficients are listed in the Table 2 (P-value of the model is below 0.0001). An error term, ε, has a zero mean and the standard deviation of 551 MW/0.1 Hz. This multiple regression model accounts for 19.96% of the variability in Frequency Response data.

Table 2: Parameter Estimates of Multiple Regression

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	1325.96255	243.49079	5.45	<.0001
A>60	1	-317.95091	88.191	-3.61	0.0004
Interconnection Load	1	0.00347	0.00068929	5.03	<.0001

Note that even though time and summer both have a statistically significant positive correlation with Frequency Response, adding one or both of them to the set of explanatory variables does not improve the linear model. This can be explained by a high correlation between interconnection load and summer (0.55) and time (0.20), respectively: addition of these variables does not increase the explanatory power of the model enough to offset an increase of its cumulative error.

Appendix I – Derivation of the Median, Mean, and Linear Regression

Median

The median best represents a uniform one-dimensional dataset.

Uniform Distribution

In probability theory and statistics, the continuous uniform distribution or rectangular distribution is a family of probability distributions such that for each member of the family, all intervals of the same length on the distribution's support are equally probable. The support is defined by the two parameters, a and b, which are its minimum and maximum values.

Median

We have been taught in statistics that minimizing the sum of the differences error term provides the best estimate for the value for a uniform data set. Define a data set as one dimensional with values $\{x_1, x_2, \ldots, x_n\}$. The objective is to select a single value that best represents this data set by minimizing the sum of the residuals.

$$SDE = \sum_{i=1}^{n} \left(x_i - x_m \right)$$

Where: x_m = Best single value to represent the data set.

The result is undefined using calculus. Therefore, other logic must be used.

Organize the data from smallest to largest. Then investigate the change in total difference as the candidate median value is raised from the smallest to the largest value in the data set.

When the candidate median value is raised above the smallest data value the difference between the candidate median value and the smallest value increases, but the difference between the candidate median value and all other data values decreases by an amount equal to the increase in the difference for the smallest value times the number of data values above the candidate median value. As the candidate median value increases, the total difference from all values will decrease until exactly one half of the data values are above the candidate median value and exactly one half of the data values are below the candidate median value. If there are an even number of data values in the set, any change in the candidate median value between the data value immediately below the half and the data point immediately above the half will not change the total difference because the difference change in the increasing direction and the difference change in the decreasing direction offset each other. However, if there are an odd number of data values in the data set, the candidate median value equal to the center data value will result in a minimum of the differences.

This demonstrates that the medianis the best estimate for a set of uniform data because it minimizes the sum of the error terms for the data set.

The real question is not whether the median is an appropriate estimator, but whether the median is an appropriate estimator for the data being analyzed.

Mean

The mean best represents a normal one dimensional dataset.

Normal (Gaussian) Distribution

In probability theory, the normal (or Gaussian) distribution is a continuous probability distribution that has a bell-shaped probability density function, known as the Gaussian function or informally the bell curve, where parameter μ is the mean or expectation (location of the peak) and σ^2 is the variance, the mean of the squared deviation, (a "measure" of the width of the distribution). σ is the standard deviation. The distribution with μ = 0 and $\sigma^2 = 1$ is called the standard normal. A normal distribution is often used as a first approximation to describe real-valued random variables that cluster around a single mean value.

The normal distribution is considered the most prominent probability distribution in statistics. There are several reasons for this:

- First, the normal distribution is very tractable analytically, that is, a large number of results involving this distribution can be derived in explicit form.
- Second, the normal distribution arises as the outcome of the central limit theorem, which states that under mild conditions the sum of a large number of random variables is distributed approximately normally.
- Third, the bell shape of the normal distribution makes it a convenient choice for modeling a large variety of random variables encountered in practice.

For this reason, the normal distribution is commonly encountered in practice, and is used throughout statistics, natural sciences, and social sciences as a simple model for complex phenomena. For example, the observational error in an experiment is usually assumed to follow a normal distribution, and the propagation of uncertainty is computed using this assumption. Note that a normally-distributed variable has a symmetric distribution about its mean. Quantities that grow exponentially, such as prices, incomes or populations, are often skewed to the right, and hence may be better described by other distributions, such as the log-normal distribution or Pareto distribution. In addition, the probability of seeing a normally-distributed value that is far (i.e., more than a few standard deviations) from the mean drops off extremely rapidly. As a result, statistical inference using a normal distribution is not robust to the presence of outliers (data that is unexpectedly far from the mean, due to exceptional circumstances, observational error, etc.). When outliers are expected, data may be better described using a heavy-tailed distribution such as the Student's t-distribution.

Mean

We have been taught in statistics that minimizing the sum of the squares of the error term provides the best estimate for the value for a normal data set. Let's define a data set as one dimensional with values $\{x_1, x_2, \ldots, x_n\}$. The objective is to select a single value that best represents this data set by minimizing the sum of the squares of the residuals.

$$SSE = \sum_{i=1}^{n} \left(x_i - x_m \right)^2$$

Where: x_m = Best single value to represent the data set.

$$SSE = \sum_{i=1}^{n} \left(x_i^2 - 2x_i x_m + x_m^2 \right)$$

$$SSE = \sum_{i=1}^{n} x_i^2 - \sum_{i=1}^{n} 2x_i x_m + \sum_{i=1}^{n} x_m^2$$

$$SSE = \sum_{i=1}^{n} x_i^2 - \sum_{i=1}^{n} 2x_i x_m + nx_m^2$$

Take the derivative of ***SSE*** with respect to x_m, and set that derivative equal to zero.

$$\frac{\partial}{\partial x_m} SSE = \frac{\partial}{\partial x_m} \left(\sum_{i=1}^{n} x_i^2 - \sum_{i=1}^{n} 2x_i x_m + nx_m^2 \right)$$

$$\frac{\partial}{\partial x_m} SSE = \frac{\partial}{\partial x_m} \left(\sum_{i=1}^{n} x_i^2 \right) - \frac{\partial}{\partial x_m} \left(\sum_{i=1}^{n} 2x_i x_m \right) + \frac{\partial}{\partial x_m} \left(nx_m^2 \right)$$

$$\frac{\partial}{\partial x_m} SSE = -2\sum_{i=1}^{n} x_i + 2nx_m = 0$$

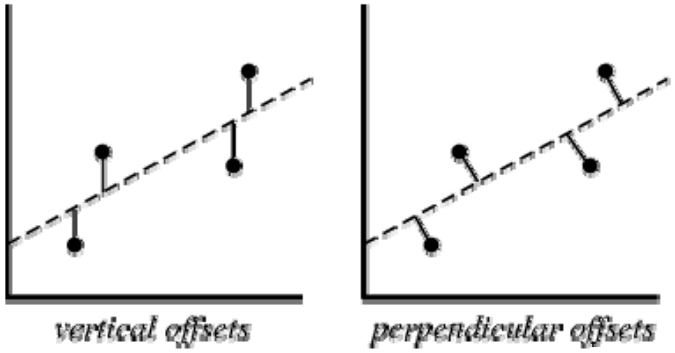
$$\frac{1}{n} \sum_{i=1}^{n} x_i = x_m = \bar{x}$$

This demonstrates that the mean is the best estimate for a set of normal data because it minimizes the sum of the squares of the error terms for the data set.

Linear Regression

A linear regression best represents a normal two dimensional dataset.

As with the one dimensional data set, the objective is to minimize the sum of the squares of the error terms. However, there may be differences that depend upon how we define the error terms.



There are three alternatives available for defining the error term. It can be defined with respect to the dependent variable alone as shown in the vertical offsets plot above. The second is to define the error in terms of the horizontal offsets (not shown). That alternative is the same as the first alternative when the independent variable is exchanged with the dependent variable. The third alternative is to define the error as the perpendicular distance from the best fit line. This is shown in the perpendicular offsets plot above. When the regression is solved using the perpendicular offsets, both variables are considered equal with respect to contribution to error, and the ranking of variables is not necessary.

Solution assuming an independent/dependent variable relationship

In the first example the error term is defined as one dimensional on the dependent variable axis. This is based on the vertical offsets shown above. The result is derived as follows:

$$SSE = \sum_{i=1}^{n} \left(y_i - \hat{y}_i \right)^2$$

Where: $\hat{y}_i$ = Best y value to represent the data set at a given x value.

Substitute a linear equation, $\hat{y}_i = ax_i + b$, for the estimated y value.

$$SSE = \sum_{i=1}^{n} \left(y_i - ax_i - b \right)^2$$

Since we now have two variables, a and b, the derivative must be taken with respect to each variable. Setting each derivative equal to zero will provide two equations that can be solved for the two unknowns, a and b.

$$\frac{\partial}{\partial b} SSE = \frac{\partial}{\partial b} \sum_{i=1}^{n} \left(y_i - a x_i - b \right)^2 = -2 \sum_{i=1}^{n} \left(y_i - a x_i - b \right) = 0$$

$$\frac{\partial}{\partial a} SSE = \frac{\partial}{\partial a} \sum_{i=1}^{n} \left(y_i - a x_i - b \right)^2 = -2 \sum_{i=1}^{n} \left(x_i y_i - a x_i^2 - b x_i \right) = 0$$

Rearrange terms and solve the two equations. Solve for b first.

$$-\sum_{i=1}^{n} y_i + a \sum_{i=1}^{n} x_i + nb = 0 \quad \Rightarrow \quad b = \frac{1}{n} \sum_{i=1}^{n} y_i - a \frac{1}{n} \sum_{i=1}^{n} x_i \quad \Rightarrow \quad b = \bar{y} - a\bar{x}$$

Substitute the result for b into the second equation and solve for a.

$$-\sum_{i=1}^{n} x_i y_i + a \sum_{i=1}^{n} x_i^2 + \left(\bar{y} - a\bar{x} \right) \sum_{i=1}^{n} x_i = 0 \quad \Rightarrow \quad a = \frac{\sum_{i=1}^{n} x_i y_i - n\bar{y}\bar{x}}{\sum_{i=1}^{n} x_i^2 - n\bar{x}^2}$$

Calculate the value of a and substitute into the first equation to get the value of b. These are the most common equations used for linear regression. However, they assume that the dependent and independent variables can be identified and that the error in the dependent variable is more important than the error in the independent variable.

Solution without the independent/dependent variable relationship assumption

In this section, the problem is solved using the perpendicular offsets to determine the error terms. This provides a solution that is not dependent upon any assumption concerning the relationship between the variables.

The first step in this solution is to determine the square of the perpendicular offset from the regression line that represents the error term.

$$SSE = \sum_{i=1}^{n} \left(\frac{\left[y_i - \left(a x_i + b \right) \right]^2}{1 + a^2} \right)$$

Since we again have two variables, a and b, the derivative must be taken with respect to each variable. Setting each derivative equal to zero will provide two equations that can be solved for the two unknowns, a and b.

$$\frac{\partial}{\partial b} SSE = \frac{\partial}{\partial b} \sum_{i=1}^{n} \left(\frac{\left[y_i - \left(a x_i + b \right) \right]^2}{1 + a^2} \right) = \frac{-2}{1 + a^2} \sum_{i=1}^{n} \left(y_i - a x_i - b \right) = 0$$

$$\frac{\partial}{\partial a} SSE = \frac{\partial}{\partial a} \sum_{i=1}^{n} \left(\frac{\left[y_i - (a x_i + b) \right]^2}{1 + a^2} \right)$$

$$\frac{\partial}{\partial a} SSE = \frac{-2}{1 + a^2} \sum_{i=1}^{n} (y_i - a x_i - b) x_i - \sum_{i=1}^{n} \frac{(y_i - a x_i - b)^2 (2a)}{(1 + a^2)^2} = 0$$

Rearrange terms and solve the two equations. Solve for b first.

$$-\sum_{i=1}^{n} y_i + a \sum_{i=1}^{n} x_i + nb = 0 \quad \Rightarrow \quad b = \frac{1}{n} \sum_{i=1}^{n} y_i - a \frac{1}{n} \sum_{i=1}^{n} x_i \quad \Rightarrow \quad b = \bar{y} - a\bar{x}$$

This is the same result as before. Substitute the result for ***b*** into the second equation and solve for ***a***. The detailed intermediate equations for this solution can be found at http://mathworld.wolfram.com/LeastSquaresFittingPerpendicularOffsets.html. After much manipulation the following equations result:

$$A = \frac{1}{2} \frac{\left(\sum_{i=1}^{n} y_i^2 - n\bar{y}^2 \right) - \left(\sum_{i=1}^{n} x_i^2 - n\bar{x}^2 \right)}{n\bar{y}\bar{x} - \sum_{i=1}^{n} x_i y_i} \quad \Rightarrow \quad a = -A \pm \sqrt{A^2 + 1}$$

This solution is somewhat more complex than the vertical offset solution. That is the reason that the vertical offset solution is commonly used. In most cases, the vertical offset solution provides an adequate answer to the problem without the added complexity of the perpendicular offset solution. However, when the vertical offset solution is used, it makes a difference which variable is considered the independent variable and the dependent variable. This can significantly affect the results when the slope is large.

Additional information requires a special case linear regression

The calculation of Frequency Response requires the use of a special case linear regression. Frequency Response is defined as to be equal to zero when the frequency error is equal to zero. This information requires the modification of the linear regression used to provide the best representation of the data. The appropriate linear regression for representing Frequency Response is a regression where the regression line crosses the origin of the axis representing the two variables, frequency and Frequency Response (MW). Therefore, the previously developed general solution to the problem requires modification. This is done by setting the variable that represents the ***y-intercept*** to zero. In the above examples, the ***b*** term must be set to zero.

Special case solution assuming an independent/dependent variable relationship

In the first example the error term is defined as one dimensional on the dependent variable axis. This is based on the vertical offsets but in this case the variable representing the intercept is eliminated. The result is derived as follows:

$$SSE = \sum_{i=1}^{n} \left(y_i - \hat{y}_i \right)^2$$

Where: $\hat{y}_i$ = Best ***y*** value to represent the data set at a given ***x*** value.

Substitute a linear equation, $\hat{y}_i = ax_i$, for the estimated ***y*** value.

$$SSE = \sum_{i=1}^{n} \left(y_i - ax_i \right)^2$$

Since we now have a single variables, ***a***, the derivative must be taken with respect to that variable. Setting the derivative equal to zero will provide an equation that can be solved for the unknown, ***a***.

$$\frac{\partial}{\partial a} SSE = \frac{\partial}{\partial a} \sum_{i=1}^{n} \left(y_i - ax_i \right)^2 = -2 \sum_{i=1}^{n} \left(x_i y_i - ax_i^2 \right) = 0$$

Rearrange terms and solve the equation.

$$-\sum_{i=1}^{n} x_i y_i + a \sum_{i=1}^{n} x_i^2 = 0 \qquad \Rightarrow \qquad a = \frac{\sum_{i=1}^{n} x_i y_i}{\sum_{i=1}^{n} x_i^2}$$

This equation is somewhat simpler than the equation using a non-zero intercept. In the specific case that we are considering, the estimate of Frequency Response, the slope of the regression line is not expected to be large, near vertical. Therefore, the assumption of dependent and independent variables is not important to the solution. In this case, the additional complexity added by considering the horizontal offsets is not significant to the solution and has been eliminated from consideration.

Appendix J – Generator Governor Survey Instructions

NOTE: These were the instructions for the Generators Governor Survey conducted in September 2010.

Frequency Response Initiative

Generator Governor Survey

For the purposes of this survey, governors are defined as any device that implements Primary Frequency Response (speed regulation) for generators.

The survey will be sent to Generator Owners and Generator Operators.

- The survey includes all generators rated 20 MVA or higher, or plants that aggregate to a total of 75 MVA or greater net rating at the point of interconnection (i.e., wind farms, PV farms, etc.), accordance with the Statement of Compliance Registry Criteria, Rev. 5.0.
- Jointly-owned units should be reported by the operating entity.
- For combined-cycle plants, the combustion turbines and heat-recovery (steam turbine) units should be reported separately.
- Wind farms should report on a point-of-interconnection basis.
- If the unit is operable in more than one interconnection, complete the survey for operation in each of the interconnections.

NOTE: The 256-character limitation noted on the spreadsheet is a Microsoft Excel limitation on characters in a cell. If additional space is needed, please supply supplemental documentation as necessary.

When responding, please upload your response and any supporting documentation through the NERC Secure Alerts System

General Questions

1. Does your organization have a formal policy on the installation and operation of generator governors?
2. Does your organization have a testing procedure for governors? If so, how often are they tested?

Unit-Specific Questions

The following questions will all apply to each generator:

1. Unit name and number.

2. Balancing Authority (BA) in which the generator is operated (pull-down).
   a. If operable in more than one, please note all applicable BAs.
   b. If operable in more than one interconnection, complete the survey for operation in each of the interconnections.
3. Unit seasonal Net MW ratings normally reported to NERC for resource adequacy analyses:
   a. Summer Net MW rating
   b. Winter Net MW rating
4. Prime mover (steam turbine, combustion turbine, wind turbine, etc. — pull-down)
5. Fuel type (coal, oil, nuclear, etc. — pull-down)
6. Unit inertia constant (H) as modeled in dynamics analyses – the combined kinetic energy of the generator and prime-mover in watt-seconds at rated speed divided by the VA (Volt-Ampere) base.
7. What are the annual run hours for the unit (data for each of the last 3 years)?
8. What is the continuous MW rating (Pmax) of the unit?
9. What percent of time does the unit run at Pmax or valves wide-open?
   a. 0 to 30%
   b. 31% to 60%
   c. 61% to 100%
10. Equipped with a Governor? (Y/N) If not, no further answers are necessary.
11. If yes, is the governor operational? (Y/N with a comment box) If not, please explain.
   a. Is the governor normally in operation? (Y/N with a comment box) (even if not normally operated, the data on the governor is still needed)
   b. What is the normal governor mode of operation? (pull-down)
   c. Is the governor response sustainable for more than one minute if conditions remain outside of the deadband? (Y/N)
   d. Are there any regulatory restrictions regarding the operation of the governor? This should cover nuclear regulation, environmental restrictions (water temperature, emissions), water flow, etc.
   e. Does the governor respond beyond the high/low operating limit (boiler blocks)? (Y/N)
   f. Is the governor response limited by the rate of change? (Y/N)
   g. Are there any other unit-level or plant-level control schemes that would override or limit governor performance? If yes, please explain.
12. Governor Type?
   - Electronic (analog electro-hydraulic);
   - DEH (digital electro hydraulic);
   - Mechanical;
   - Other — please specify.
13. Governor manufacturer and model?
   a. If mixed vendor equipment is installed, please explain.
14. Governor Deadband setting?
   a. Deadband in(+/-) mHz

i. If in mHz is the deadband centered around a frequency reference (60 Hz or current frequency)?

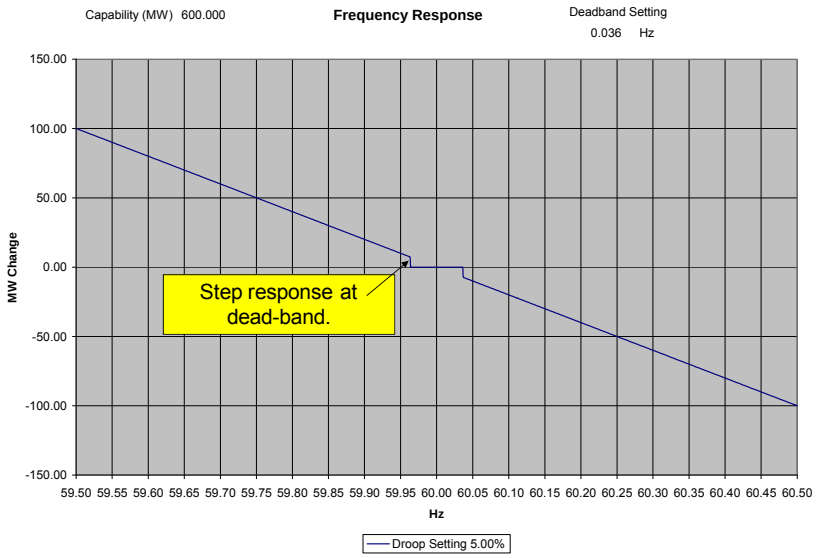
b. Deadband in (+/-) RPM
   i. For RPM specify number of machine poles
   ii. If in RPM, is the RPM reference nominal or current RPM?

c. What is the basis for this setting?

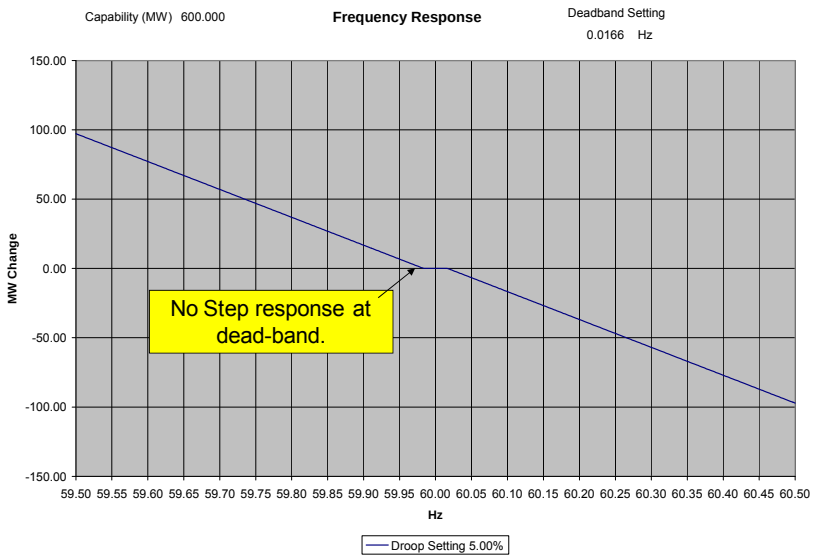
d. Once activated, what are the conditions for which the governor action is reset?

15. What is the percentage (%) droop setting on the governor?
    a. What is the basis for the droop setting?

16. Does the unit Frequency Response step into the droop curve or is it linear from the deadband?



Step Implementation (step): When frequency crosses the governor dead-band setting the output of the governor “steps” into the 5% droop curve as if the dead-band did not exist.



Without Step Implementation (linear): When frequency crosses the governor dead-band setting the output of the governor adds proportional output toward the droop curve end point.

17. Prime mover control mode – What is the normally used Turbine Control mode(s)? If more than one is prevalently used, select a primary and explain.
    - Turbine manual
    - Thermally-limited
    - Turbine following
    - Boiler following
    - Part-load
    - Pre-select
    - MW set point
    - Coordinated control
    - Other (please explain) If more than one is prevalently used, select a primary and explain.

18. Do market rules restrict or override governor speed controls? (Y/N) If yes, please explain.

For steam generator controls (boiler controls) or combined cycle central station controls:

19. Does the boiler control or combined cycle central station control have a frequency input? (Y/N) If yes, answer the following questions:
    a. Deadband in(+/-) mHz
        i. If in mHz is the deadband centered around a frequency reference (60 Hz or current frequency)?

b. Deadband in (+/-) RPM
    i. For RPM specify number of machine Poles
    ii. If in RPM, is the RPM reference nominal or current RPM?
c. What is the basis for this setting?

20. Does the control's Frequency Response step into the droop curve or is it linear from the deadband?
21. What is the steam turbine control mode? (boiler following, turbine following, coordinated control)
22. Do the unit or plant controls over-ride governor speed control or are the control parameters supportive? (Y/N)
23. Does the boiler operate under variable/sliding pressure? (Y/N)
    a. What is the control/governor valve position percentage (%) during variable pressure operation?
24. Do unit or plant economic controls over-ride governor speed control? (Y/N)

Event Performance Data

The following five questions are to be answered for each generator to ascertain its performance during the specified frequency events (one per interconnection). The frequency events data to be reported are:

Interconnection	Date	Time	Time Zone
Eastern	8/16/2010	14:25:29	CST
Western	8/12/2010	1:06:15	CST
Texas	8/20/2010	14:44:03	CST
Québec	12/10/2009	15:09:31	EST

25. Was the unit on-line during the event? (Y/N)
26. Pre-event generation (MW) – Enter the MW output of the generator at the time just before the event began.
27. Post-event generation (MW) – Enter the MW output of the generator after the event that was reflects the response by the governor to the frequency deviation.
28. Time to achieve post-event response (seconds) – Enter the time (in seconds) it took to achieve the MW response noted in question 27.
29. Comments (256 characters) – Enter any comments necessary. If no data is available for the event, note that here.

Analysis of Eastern Interconnection Frequency Response, February 2011. NERC

Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet. Cell G1 with the BA name. Cells R11 through R13 with contact information. Cell R24 with BA Bias Type, Fixed or Variable.

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.

Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data.
Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs.
b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on 100% of your FRM.
c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on 125% of your FRM.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting.
b) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
f) The comparison to the FBS minimum will be from two previous year's analysis prior to the current year and the dates in the table starting at J3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.

Step 7 Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard.
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern +/-0.500 Hz, Western +/-0.500 Hz, ERCOT +/-0.700 Hz and HQ +/-1.500 Hz.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.

Step 8 Send completed Form 1 and each Form 2 to NERC.

Balancing Authority: MyBA

1901	Bias Calculation Form 1 for Year
Eastern	Interconnection
MyBA	Balancing Authority
	Contact Name
	Contact Phone #
	Contact e-mail
	MWh Annual Gen$_{BA}$ is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
	MWh Annual Load$_{BA}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
	MWh Annual Gen$_{INT}$ is the Sum of all Annual Gen$_{BA}$ values in this interconnection
	MWh Annual Load$_{INT}$ is the Sum of all Annual Load$_{BA}$ values in this interconnection
-964	Interconnection Frequency Response Obligation (FRO) MW/0.1 Hz Determined by ERO
1900	Current data year (December thru November)
#DIV/0!	**1901 BA Frequency Response Obligation (FRO) for next year's FRM**
	1900 BA Frequency Response Obligation (FRO) for this year's FRM from your last year's Form 1.
Calculate Regression	
	BA Bias Type and Bias Setting
Fixed	Bias Type utilized.
0.90%	Interconnection Minimum Fixed Frequency Bias Setting % of Peak Demand or Peak Generation (Set by ERO)
621018	The Sum of the Non-Coincident peak demands for all Bas on the interconnection from FERC Form No. 714, provided by ERO.
#DIV/0!	Your BA's lowest absolute Fixed Frequency Bias Setting based on interconnection non-coincident peak demand.
#DIV/0!	Your BA's lowest absolute Fixed Frequency Bias Setting based on 100% of FRM.
#DIV/0!	Your BA's highest absolute Fixed Bias Setting: 125% of FRM.
n/a	Balancing Authority lowest absolute Variable Bias Setting (least negative one minute average Bias while frequency is less than 59.964 or greater than 60.036 Hz).
-20.87	Balancing Authority desired Bias Setting: May be set to a value between 100% to 125% of its FRM if this value is more negative than the minimum Bias based on Peak Demand. If not more negative, then the Bias must be the minimum Bias based on Peak Demand. If variable Bias is used, enter "Variable".
#DIV/0!	**1901 Frequency Bias Setting - (minimum of 100% to 125% of FRM, or 0.9% of Historical Peak Demand if not Variable)**
#DIV/0!	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for Bias
0.00	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
#DIV/0!	1900 FRM - Median Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
0.00	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for R1
0.00	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for R1
0.00	**1900 FRM - Median Estimated Frequency Response MW/0.1Hz for BA Compliance to R1, minimum Frequency Response**
N	Do you RECEIVE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA in the table below.

Bias -MW/0.1 Hz	Balancing Authority

N	Do you PROVIDE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA

Bias -MW/0.1 Hz	Balancing Authority

Instructions

Step 1 Enter data in all green cells on this "Data Entry" worksheet.

Step 2 For identified events in column B, collect data and complete FRS Form 2.9 for each event in the list.

Step 3 PasteSpecial/Values data from FRS Form 2.9 "Form 1 Summary Data" into "BA Form 2 Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsm and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your BA name)

MyBA_1901_FRS_Form_1.9.xlsm

Sign Convention for scan data collected in Form 2	Imports: MWs are - Exports: MWs are +	Loads in MW as -	Load MW as - Generation MW as +	Enter Gen MW as +	The transactional amount in MW Receiver enters - Deliverer enters + on Form 2 Data sheet	Generation MW as + (If demand occurs due to gen loss, enter MW as - at value B)

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify:
   - Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made.
   - Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
   Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.
   - Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).

2) Dynamic Schedules:
   - Values use schedule sign convention.
   - Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.

3) Nonconforming Loads:
   - Values must be negative numbers.

4) Pumped Hydro:
   - Values for pumping must be negative values.
   - Values for generating must be positive values.

5) Rampling Units:
   - Values are positive values.

6) Transferred Frequency Response:
   - This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced.
   (e.g. if an entity agrees to provide 20 MW/0.1 Hz to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
   - Values for the entity receiving the response must be entered as a negative number.
   - Values for the entity delivering the response must be entered as a positive number.
   - Values between entities must sum to zero.

7) Contingent Balancing Authority Adjustment:
   - Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
   - Data for Value B is usually 0 MW, but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

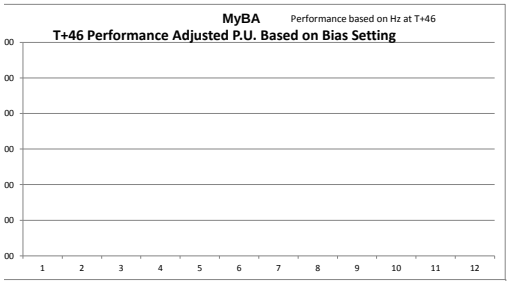
FRI - NERC Frequency Response Initiative

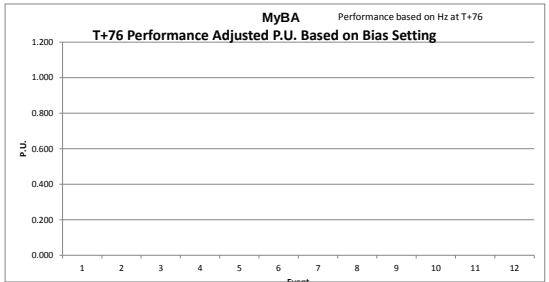
The FRI Report made recommendations to evaluate Primary Frequency Response at additional time intervals during the event recovery period.
Additional evaluations have been added to both Form 1 and Form 2 to evaluate PFR delivery for these suggested time periods.
These evaluations utilize Interconnection frequency at specific times during the recovery period and calculates the BA's delivery of PFR for each selection.
These evaluations are not part of BAL-003 and will not impact compliance to R1 of the draft standard.
The following time selections are evaluated: T+46, T+76, T+106, T+136 and T+166.
Each evaluation is a P.U. measure based on the BA's Bias setting at each of these times.
Performance is the "best" performance at the specific time through 10 seconds past each time.
This is intended to account for any delay in data in the measurement. This measurement may be changed as experience in this effort increases.

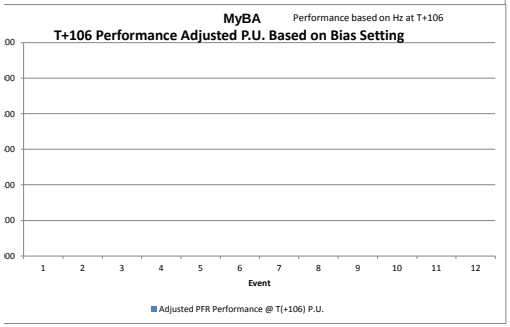
Also included is the measure of PFR delivery during the T+20 to T+52 second period, the same as R1 of the standard.
The measure (P.U.) here is based on the BA Bias setting and not the FRO. This was done to provide comparison to the additional measurement times.

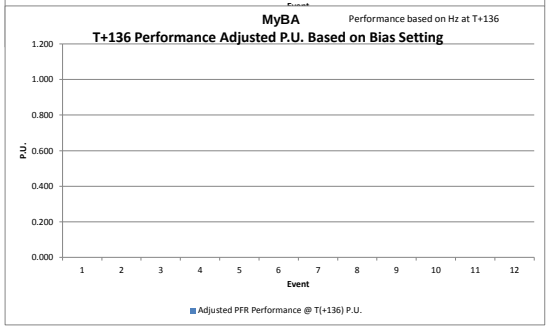
Some basic observations from this data:

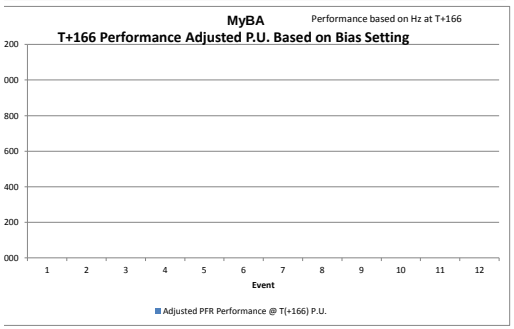
1) If the P.U. value is close to 1.0, the BA delivered the full amount of PFR equal to its Bias setting.
2) The average performance of the Eastern Interconnection in PFR is about 40% of the total Interconnection Bias setting. If the BA's average score is greater than 0.40 P.U. then they are providing more PFR than the average BA. If the P.U. is less than 40% then they are providing less than average PFR.
3) If the P.U. value at T+46 is consistently less than the P.U. value at T+20 to T+52, then the PFR of the BA is not being sustained.
4) If the P.U. value at later time interval measures is consistently less, then withdrawal of PFR is occurring at a slower rate, but still being withdrawn.
5) If the P.U. value at T+20 to T+52, T+46, or T+76 is consistently greater than 1.0, this indicates that the BA Bias setting is too low.











Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet. Cell G1 with the BA name. Cells R11 through R13 with contact information. Cell R24 with BA Bias Type, Fixed or Variable.

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.

Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data.
Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs.
b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on 100% of your FRM.
c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on 125% of your FRM.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting.
b) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
f) The comparison to the FBS minimum will be from two previous year's analysis prior to the current year and the dates in the table starting at J3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.

Step 7 Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard.
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern +/-0.500 Hz, Western +/-0.500 Hz, ERCOT +/-0.700 Hz and HQ +/-1.500 Hz.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.

Step 8 Send completed Form 1 and each Form 2 to NERC.

1901	Bias Calculation Form 1 for Year
ERCOT	Interconnection
ERCOT	Balancing Authority
	Contact Name
	Contact Phone #
	Contact e-mail
1	MWh Annual Gen_{BA} is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
1	MWh Annual $Load_{BA}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
1	MWh Annual Gen_{INT} is the Sum of all Annual Gen_{BA} values in this interconnection
1	MWh Annual $Load_{INT}$ is the Sum of all Annual $Load_{BA}$ values in this interconnection
-286	Interconnection Frequency Response Obligation (FRO) MW/0.1 Hz. Determined by ERO.
1900	Current data year (December thru November)
-286.00	**1901 BA Frequency Response Obligation (FRO) for next year's FRM**
-286.00	**1900 BA Frequency Response Obligation (FRO) for this year's FRM from your last year's Form 1.**
Calculate Regression	
	BA Bias Type and Bias Setting
Fixed	Bias Type utilized.
0.90%	Interconnection Minimum Fixed Frequency Bias Setting % of Peak Demand or Peak Generation (Set by ERO)
65300	The Sum of the Non-Coincident peak demands for all Bas on the interconnection from FERC Form No. 714, provided by ERO.
-587.70	Your BA's lowest absolute Fixed Frequency Bias Setting based on interconnection non-coincident peak demand.
#DIV/0!	Your BA's lowest absolute Fixed Frequency Bias Setting based on 100% of FRM.
#DIV/0!	Your BA's highest absolute Fixed Bias Setting: 125% of FRM.
n/a	Balancing Authority lowest absolute Variable Bias Setting (least negative one minute average Bias while frequency is less than 59.964 or greater than 60.036 Hz).
-653.00	Balancing Authority desired Bias Setting: Single BA Interconnections have no minimum or maximum Bias Setting requirement. If variable Bias is used, enter "Variable".
-653.00	**1901 Frequency Bias Setting - (Single BA Interconnections have no minimum or maximum Bias Setting requirement)**
#DIV/0!	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for Bias
-529.36	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
#DIV/0!	1900 FRM - Median Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
0.00	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for R1
-529.36	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for R1
0.00	**1900 FRM - Median Estimated Frequency Response MW/0.1Hz for BA Compliance to R1, minimum Frequency Response**
N	Do you RECEIVE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA in the table below.

Bias -MW/0.1 Hz	Balancing Authority

N	Do you PROVIDE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA

Bias -MW/0.1 Hz	Balancing Authority

Enter data in all green cells on this "Data Entry" worksheet.

For identified events in column B, collect data and complete FRS Form 2.9 for each event in the list.

PasteSpecial/Values data from FRS Form 2.9 "Form 1 Summary Data" into "BA Form 2 Data" worksheet of this workbook. Do this for each event in the list.

Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsm and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your BA name)

ERCOT_1901_FRS_Form_1.9.xlsm

Sign Convention for scan data collected in Form 2	Imports: MWs are - Exports: MWs are +	Loads in MW as -	Load MW as - Generation MW as +	Enter Gen MW as +	The transactional amount in MW Receiver enters - Deliverer enters + on Form 2 Data sheet	Generation MW as + (If demand occurs due to gen loss, enter MW as - at value B)

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify:
   - Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made.
   - Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
   Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.
   - Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).

2) Dynamic Schedules:
   - Values use schedule sign convention.
   - Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.

3) Nonconforming Loads:
   - Values must be negative numbers.

4) Pumped Hydro:
   - Values for pumping must be negative values.
   - Values for generating must be positive values.

5) Rampling Units:
   - Values are positive values.

6) Transferred Frequency Response:
   - This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced. (e.g. if an entity agrees to provide 20 MW/0.1 Hz to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
   - Values for the entity receiving the response must be entered as a negative number.
   - Values for the entity delivering the response must be entered as a positive number.
   - Values between entities must sum to zero.

7) Contingent Balancing Authority Adjustment:
   - Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
   - Data for Value B is usually 0 MW, but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

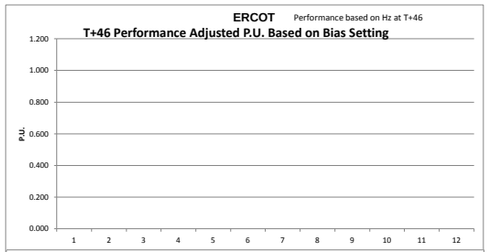
FRI - NERC Frequency Response Initiative

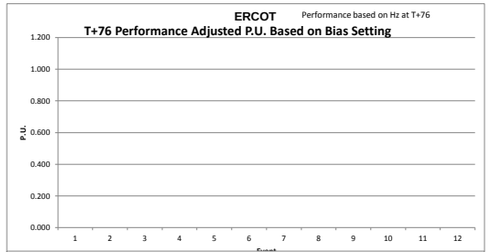
The FRI Report made recommendations to evaluate Primary Frequency Response at additional time intervals during the event recovery period.
Additional evaluations have been added to both Form 1 and Form 2 to evaluate PFR delivery for these suggested time periods.
These evaluations utilize Interconnection frequency at specific times during the recovery period and calculates the BA's delivery of PFR for each selection.
These evaluations are not part of BAL-003 and will not impact compliance to R1 of the draft standard.
The following time selections are evaluated: T+46, T+76, T+106, T+136 and T+166.
Each evaluation is a P.U. measure based on the BA's Bias setting at each of these times.
Performance is the "best" performance at the specific time through 10 seconds past each time.
This is intended to account for any delay in data in the measurement. This measurement may be changed as experience in this effort increases.

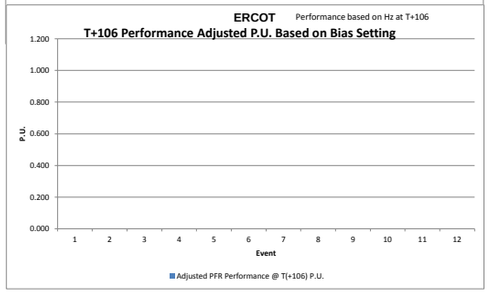
Also included is the measure of PFR delivery during the T+20 to T+52 second period, the same as R1 of the standard.
The measure (P.U.) here is based on the BA Bias setting and not the FRO. This was done to provide comparison to the additional measurement times.

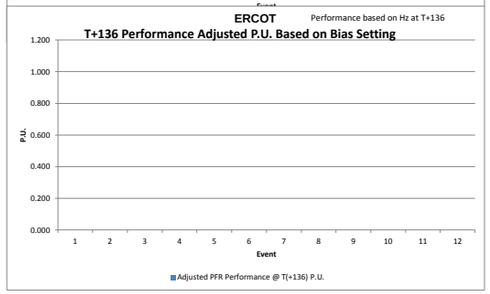
Some basic observations from this data:

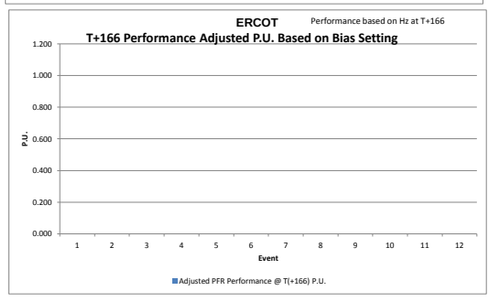
1) If the P.U. value is close to 1.0, the BA delivered the full amount of PFR equal to its Bias setting.
2) The average performance of the Eastern Interconnection in PFR is about 40% of the total Interconnection Bias setting. If the BA's average score is greater than 0.40 P.U. then they are providing more PFR than the average BA. If the P.U. is less than 40% then they are providing less than average PFR.
3) If the P.U. value at T+46 is consistently less than the P.U. value at T+20 to T+52, then the PFR of the BA is not being sustained.
4) If the P.U. value at later time interval measures is consistently less, then withdrawal of PFR is occurring at a slower rate, but still being withdrawn.
5) If the P.U. value at T+20 to T+52, T+46, or T+76 is consistently greater than 1.0, this indicates that the BA Bias setting is too low.











Instructions

004332

Step 1 Enter data in all green cells on the "Data Entry" worksheet. Cell G1 with the BA name. Cells R11 through R13 with contact information. Cell R24 with BA Bias Type, Fixed or Variable.

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.

Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data.
Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs.
b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on 100% of your FRM.
c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on 125% of your FRM.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting.
b) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
f) The comparison to the FBS minimum will be from two previous year's analysis prior to the current year and the dates in the table starting at J3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.

Step 7 Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard.
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern +/-0.500 Hz, Western +/-0.500 Hz, ERCOT +/-0.700 Hz and HQ +/-1.500 Hz.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.

Step 8 Send completed Form 1 and each Form 2 to NERC.

NERC FRS FORM 1 20 to 52 second Value B

Balancing Authority HQT

1	MWh Annual Gen_{BA} is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
1	MWh Annual $Load_{BA}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
1	MWh Annual Gen_{INT} is the Sum of all Annual Gen_{BA} values in this interconnection
1	MWh Annual $Load_{INT}$ is the Sum of all Annual $Load_{BA}$ values in this interconnection
-179	Interconnection Frequency Response Obligation (FRO) MW/0.1 Hz. Determined by ERO.
1900	Current data year (December thru November)
-179.00	**1901 BA Frequency Response Obligation (FRO) for next year's FRM**
-179.00	**1900 BA Frequency Response Obligation (FRO) for this year's FRM from your last year's Form 1.**
Calculate Regression	**BA Bias Type and Bias Setting**
Fixed	Bias Type utilized.
0.90%	Interconnection Minimum Fixed Frequency Bias Setting % of Peak Demand or Peak Generation (Set by ERO)
37153	The Sum of the Non-Coincident peak demands for all Bas on the interconnection from FERC Form No. 714, provided by ERO.
-334.38	Your BA's lowest absolute Fixed Frequency Bias Setting based on interconnection non-coincident peak demand.
#DIV/0!	Your BA's lowest absolute Fixed Frequency Bias Setting based on 100% of FRM.
#DIV/0!	Your BA's highest absolute Fixed Bias Setting: 125% of FRM.
n/a	Balancing Authority lowest absolute Variable Bias Setting (least negative one minute average Bias while frequency is less than 59.964 or greater than 60.036 Hz).
-442.00	Balancing Authority desired Bias Setting: Single BA Interconnections have no minimum or maximum Bias Setting requirement. If variable Bias is used, enter "Variable".
-442.00	**1901 Frequency Bias Setting - (Single BA Interconnections have no minimum or maximum Bias Setting requirement)**
#DIV/0!	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for Bias
0.00	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
#DIV/0!	1900 FRM - Median Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
0.00	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for R1
0.00	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for R1
0.00	**1900 FRM - Median Estimated Frequency Response MW/0.1Hz for BA Compliance to R1, minimum Frequency Response**
N	Do you RECEIVE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA in the table below.

Bias -MW/0.1 Hz	Balancing Authority

N	Do you PROVIDE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA

Bias -MW/0.1 Hz	Balancing Authority

Instructions

Step 1 Enter data in all green cells on this "Data Entry" worksheet.

Step 2 For identified events in column B, collect data and complete FRS Form 2.9 for each event in the list.

Step 3 PasteSpecial/Values data from FRS Form 2.9 "Form 1 Summary Data" into "BA Form 2 Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsm and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your BA name)

HQT_1901_FRS_Form_1.9.xlsm

Sign Convention for scan data collected in Form 2	Imports: MWs are - Exports: MWs are +	Loads in MW as -	Load MW as - Generation MW as +	Enter Gen MW as +	The transactional amount in MW Receiver enters - Deliverer enters + on Form 2 Data sheet	Generation MW as + (If demand occurs due to gen loss, enter MW as - at value B)

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify:
   - Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made.
   - Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
     Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.
   - Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).

2) Dynamic Schedules:
   - Values use schedule sign convention.
   - Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.

3) Nonconforming Loads:
   - Values must be negative numbers.

4) Pumped Hydro:
   - Values for pumping must be negative values.
   - Values for generating must be positive values.

5) Rampling Units:
   - Values are positive values.

6) Transferred Frequency Response:
   - This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced.
     (e.g. if an entity agrees to provide 20 MW/0.1 Hz to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
   - Values for the entity receiving the response must be entered as a negative number.
   - Values for the entity delivering the response must be entered as a positive number.
   - Values between entities must sum to zero.

7) Contingent Balancing Authority Adjustment:
   - Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
   - Data for Value B is usually 0 MW, but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

FRI - NERC Frequency Response Initiative

The FRI Report made recommendations to evaluate Primary Frequency Response at additional time intervals during the event recovery period.
Additional evaluations have been added to both Form 1 and Form 2 to evaluate PFR delivery for these suggested time periods.
These evaluations utilize Interconnection frequency at specific times during the recovery period and calculates the BA's delivery of PFR for each selection.
These evaluations are not part of BAL-003 and will not impact compliance to R1 of the draft standard.
The following time selections are evaluated: T+46, T+76, T+106, T+136 and T+166.
Each evaluation is a P.U. measure based on the BA's Bias setting at each of these times.
Performance is the "best" performance at the specific time through 10 seconds past each time.
This is intended to account for any delay in data in the measurement. This measurement may be changed as experience in this effort increases.

Also included is the measure of PFR delivery during the T+20 to T+52 second period, the same as R1 of the standard.
The measure (P.U.) here is based on the BA Bias setting and not the FRO. This was done to provide comparison to the additional measurement times.

Some basic observations from this data:

1) If the P.U. value is close to 1.0, the BA delivered the full amount of PFR equal to its Bias setting.
2) The average performance of the Eastern Interconnection in PFR is about 40% of the total Interconnection Bias setting. If the BA's average score is greater than 0.40 P.U. then they are providing more PFR than the average BA. If the P.U. is less than 40% then they are providing less than average PFR.
3) If the P.U. value at T+46 is consistently less than the P.U. value at T+20 to T+52, then the PFR of the BA is not being sustained.
4) If the P.U. value at later time interval measures is consistently less, then withdrawal of PFR is occurring at a slower rate, but still being withdrawn.
5) If the P.U. value at T+20 to T+52, T+46, or T+76 is consistently greater than 1.0, this indicates that the BA Bias setting is too low.

Sign Convention for scan data collected in Form 2	Imports: MWs are - Exports: MWs are +	Loads in MW as -	Load MW as - Generation MW as +	Enter Gen MW as +	The transactional amount in MW Receiver enters - Deliverer enters + on Form 2 Data sheet	Generation MW as + (If demand occurs due to gen loss, enter MW as - at value B)

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify:
   - Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made.
   - Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
     Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.
   - Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).

2) Dynamic Schedules:
   - Values use schedule sign convention.
   - Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.

3) Nonconforming Loads:
   - Values must be negative numbers.

4) Pumped Hydro:
   - Values for pumping must be negative values.
   - Values for generating must be positive values.

5) Rampling Units:
   - Values are positive values.

6) Transferred Frequency Response:
   - This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced.
     (e.g. if an entity agrees to provide 20 MW/0.1 Hz to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
   - Values for the entity receiving the response must be entered as a negative number.
   - Values for the entity delivering the response must be entered as a positive number.
   - Values between entities must sum to zero.

7) Contingent Balancing Authority Adjustment:
   - Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
   - Data for Value B is usually 0 MW, but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet. Cell G1 with the BA name. Cells R11 through R13 with contact information. Cell R24 with BA Bias Type, Fixed or Variable.

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.

Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data.
Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs.
b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on 100% of your FRM.
c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on 125% of your FRM.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting.
b) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
f) The comparison to the FBS minimum will be from two previous year's analysis prior to the current year and the dates in the table starting at J3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.

Step 7 Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard.
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern +/-0.500 Hz, Western +/-0.500 Hz, ERCOT +/-0.700 Hz and HQ +/-1.500 Hz.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.

Step 8 Send completed Form 1 and each Form 2 to NERC.

Balancing Authority: ERCOT

NERC FRS FORM 1 20 to 52 second Value B

Enter Addition Data in column W ==>

1901	Bias Calculation Form 1 for Year
ERCOT	Interconnection
ERCOT	Balancing Authority
	Contact Name
	Contact Phone #
	Contact e-mail
1	MWh Annual Gen_{BA} is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
1	MWh Annual $Load_{BA}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
1	MWh Annual Gen_{INT} is the Sum of all Annual Gen_{BA} values in this interconnection
1	MWh Annual $Load_{INT}$ is the Sum of all Annual $Load_{BA}$ values in this interconnection
-286	Interconnection Frequency Response Obligation (FRO) MW/0.1 Hz. Determined by ERO.
1900	Current data year (December thru November)
-286.00	**1901 BA Frequency Response Obligation (FRO) for next year's FRM**
-286.00	**1900 BA Frequency Response Obligation (FRO) for this year's FRM from your last year's Form 1.**
Calculate Regression	**BA Bias Type and Bias Setting**
Fixed	Bias Type utilized.
0.90%	Interconnection Minimum Fixed Frequency Bias Setting % of Peak Demand or Peak Generation (Set by ERO)
65300	The Sum of the Non-Coincident peak demands for all Bas on the interconnection from FERC Form No. 714, provided by ERO.
-587.70	Your BA's lowest absolute Fixed Frequency Bias Setting based on interconnection non-coincident peak demand.
#DIV/0!	Your BA's lowest absolute Fixed Frequency Bias Setting based on 100% of FRM.
#DIV/0!	Your BA's highest absolute Fixed Bias Setting: 125% of FRM.
n/a	Balancing Authority lowest absolute Variable Bias Setting (least negative one minute average Bias while frequency is less than 59.964 or greater than 60.036 Hz).
-653.00	Balancing Authority desired Bias Setting: Single BA Interconnections have no minimum or maximum Bias Setting requirement. If variable Bias is used, enter "Variable".
-653.00	**1901 Frequency Bias Setting - (Single BA Interconnections have no minimum or maximum Bias Setting requirement)**
#DIV/0!	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for Bias
-529.36	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
#DIV/0!	1900 FRM - Median Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
0.00	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for R1
-529.36	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for R1
0.00	**1900 FRM - Median Estimated Frequency Response MW/0.1Hz for BA Compliance to R1, minimum Frequency Response**
N	Do you RECEIVE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA in the table below.

Bias -MW/0.1 Hz	Balancing Authority

N	Do you PROVIDE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA

Bias -MW/0.1 Hz	Balancing Authority

Instructions

Step 1	Enter data in all green cells on this "Data Entry" worksheet.
Step 2	For identified events in column B, collect data and complete FRS Form 2.9 for each event in the list.
Step 3	PasteSpecial/Values data from FRS Form 2.9 "Form 1 Summary Data" into "BA Form 2 Data" worksheet of this workbook. Do this for each event in the list.
Step 4	Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsm and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your BA name)
	ERCOT_1901_FRS_Form_1.9.xlsm

Sign Convention for scan data collected in Form 2

Imports: MWs are -
Exports: MWs are +

Loads in MW as -

Load MW as -
Generation MW as +

Enter Gen MW as +

The transactional amount in MW Receiver enters - Deliverer enters + on Form 2 Data sheet

Generation MW as +
(If demand occurs due to gen loss, enter MW as - at value B)

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify:
   - Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made.
   - Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
     Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.
   - Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).

2) Dynamic Schedules:
   - Values use schedule sign convention.
   - Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.

3) Nonconforming Loads:
   - Values must be negative numbers.

4) Pumped Hydro:
   - Values for pumping must be negative values.
   - Values for generating must be positive values.

5) Rampling Units:
   - Values are positive values.

6) Transferred Frequency Response:
   - This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced.
     (e.g. if an entity agrees to provide 20 MW/0.1 Hz to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
   - Values for the entity receiving the response must be entered as a negative number.
   - Values for the entity delivering the response must be entered as a positive number.
   - Values between entities must sum to zero.

7) Contingent Balancing Authority Adjustment:
   - Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
   - Data for Value B is usually 0 MW, but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

1899	Reporting period FRS Form 1 data
0.00	1899 Reporting period: Balancinig Authority FRM MW/0.1 Hz, enter from FRS Form 1 for that year's FRM. If not know enter zero.
1.00%	1899 Reporting period: Interconnection Minimum Fixed Frequency Bias Setting % of Peak Demand or Peak Generation (Set by ERO)
	1899 Reporting period: Your BA's Annual Peak Demand or Peak Gen for Gen only BAs from your BA Form 714.
0.00	Your BA's lowest absolute Fixed Frequency Bias Setting based on BA Peak Demand (Peak Generation for Generation only BA) MW/0.1 Hz.
0.00	Your BA's lowest absolute Fixed Frequency Bias Setting based on 100% of FRM.
0.00	1900 Minimum, lowest absolute, conditional average Frequency Bias Setting MW/0.1 Hz.
	1899 Minimum, lowest absolute, conditional average Frequency Bias Setting MW/0.1 Hz.

*** Frequency Bias Setting (FBS)**

**** Based on the one minute values used in BAL 001 when frequency is greater than 60.036 Hz or less than 59.964 Hz.**

PasteSpecial/Values the data copied from FRS Form 2 for each event.

Event
Adjusted PFR Performance @ T(+166) P.U.

The FRI Report made recommendations to evaluate Primary Frequency Response at additional time intervals during the event recovery period.
Additional evaluations have been added to both Form 1 and Form 2 to evaluate PFR delivery for these suggested time periods.
These evaluations utilize Interconnection frequency at specific times during the recovery period and calculates the BA's delivery of PFR for each selection.
These evaluations are not part of BAL-003 and will not impact compliance to R1 of the draft standard.
The following time selections are evaluated: T+46, T+76, T+106, T+136 and T+166.
Each evaluation is a P.U. measure based on the BA's Bias setting at each of these times.
Performance is the "best" performance at the specific time through 10 seconds past each time.
This is intended to account for any delay in data in the measurement. This measurement may be changed as experience in this effort increases.

Also included is the measure of PFR delivery during the T+20 to T+52 second period, the same as R1 of the standard.
The measure (P.U.) here is based on the BA Bias setting and not the FRO. This was done to provide comparison to the additional measurement times.

Some basic observations from this data:

1) If the P.U. value is close to 1.0, the BA delivered the full amount of PFR equal to its Bias setting.
2) The average performance of the Eastern Interconnection in PFR is about 40% of the total Interconnection Bias setting. If the BA's average score is greater than 0.40 P.U. then they are providing more PFR than the average BA. If the P.U. is less than 40% then they are providing less than average PFR.
3) If the P.U. value at T+46 is consistently less than the P.U. value at T+20 to T+52, then the PFR of the BA is not being sustained.
4) If the P.U. value at later time interval measures is consistently less, then withdrawal of PFR is occurring at a slower rate, but still being withdrawn.
5) If the P.U. value at T+20 to T+52, T+46, or T+76 is consistently greater than 1.0, this indicates that the BA Bias setting is too low.

Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet. Cell G1 with the BA name. Cells R11 through R13 with contact information. Cell R24 with BA Bias Type, Fixed or Variable.

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.

Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data.
Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs.
b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on 100% of your FRM.
c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on 125% of your FRM.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting.
b) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
f) The comparison to the FBS minimum will be from two previous year's analysis prior to the current year and the dates in the table starting at J3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.

Step 7 Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard.
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern +/-0.500 Hz, Western +/-0.500 Hz, ERCOT +/-0.700 Hz and HQ +/-1.500 Hz.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.

Step 8 Send completed Form 1 and each Form 2 to NERC.

Balancing Authority: HQT

NERC FRS FORM 1 20 to 52 second Value B

1901	Bias Calculation Form 1 for Year
HQ	Interconnection
HQT	Balancing Authority
	Contact Name
	Contact Phone #
	Contact e-mail
1	MWh Annual Gen_{BA} is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
1	MWh Annual $Load_{BA}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
1	MWh Annual Gen_{INT} is the Sum of all Annual Gen_{BA} values in this interconnection
1	MWh Annual $Load_{INT}$ is the Sum of all Annual $Load_{BA}$ values in this interconnection
-179	Interconnection Frequency Response Obligation (FRO) MW/0.1 Hz. Determined by ERO.
1900	Current data year (December thru November)
-179.00	**1901 BA Frequency Response Obligation (FRO) for next year's FRM**
-179.00	**1900 BA Frequency Response Obligation (FRO) for this year's FRM from your last year's Form 1.**
Calculate Regression	**BA Bias Type and Bias Setting**
Fixed	Bias Type utilized.
0.90%	Interconnection Minimum Fixed Frequency Bias Setting % of Peak Demand or Peak Generation (Set by ERO)
37153	The Sum of the Non-Coincident peak demands for all Bas on the interconnection from FERC Form No. 714, provided by ERO.
-334.38	Your BA's lowest absolute Fixed Frequency Bias Setting based on interconnection non-coincident peak demand.
#DIV/0!	Your BA's lowest absolute Fixed Frequency Bias Setting based on 100% of FRM.
#DIV/0!	Your BA's highest absolute Fixed Bias Setting: 125% of FRM.
n/a	Balancing Authority lowest absolute Variable Bias Setting (least negative one minute average Bias while frequency is less than 59.964 or greater than 60.036 Hz).
-442.00	Balancing Authority desired Bias Setting: Single BA Interconnections have no minimum or maximum Bias Setting requirement. If variable Bias is used, enter "Variable".
-442.00	**1901 Frequency Bias Setting - (Single BA Interconnections have no minimum or maximum Bias Setting requirement)**
#DIV/0!	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for Bias
0.00	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
#DIV/0!	1900 FRM - Median Estimated Frequency Response MW/0.1Hz using SEFRD for Bias
0.00	1900 FRM - Average Estimated Frequency Response MW/0.1 Hz using SEFRD for R1
0.00	1900 FRM - Regression Estimated Frequency Response MW/0.1Hz using SEFRD for R1
0.00	**1900 FRM - Median Estimated Frequency Response MW/0.1Hz for BA Compliance to R1, minimum Frequency Response**
N	Do you RECEIVE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA in the table below.

Bias -MW/0.1 Hz	Balancing Authority

N	Do you PROVIDE Overlap regulation?
	If Yes, list the BA name and the associated Bias of that BA

Bias -MW/0.1 Hz	Balancing Authority

Instructions

Step 1 Enter data in all green cells on this "Data Entry" worksheet.

Step 2 For identified events in column B, collect data and complete FRS Form 2.9 for each event in the list.

Step 3 PasteSpecial/Values data from FRS Form 2.9 "Form 1 Summary Data" into "BA Form 2 Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsm and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your BA name)

HQT_1901_FRS_Form_1.9.xlsm

Sign Convention for scan data collected in Form 2	Imports: MWs are - Exports: MWs are +	Loads in MW as -	Load MW as - Generation MW as +	Enter Gen MW as +	The transactional amount in MW Receiver enters - Deliverer enters + on Form 2 Data sheet	Generation MW as + (If demand occurs due to gen loss, enter MW as - at value B)

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify:
   - Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made.
   - Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
     Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.
   - Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).

2) Dynamic Schedules:
   - Values use schedule sign convention.
   - Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.

3) Nonconforming Loads:
   - Values must be negative numbers.

4) Pumped Hydro:
   - Values for pumping must be negative values.
   - Values for generating must be positive values.

5) Rampling Units:
   - Values are positive values.

6) Transferred Frequency Response:
   - This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced.
     (e.g. if an entity agrees to provide 20 MW/0.1 Hz to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
   - Values for the entity receiving the response must be entered as a negative number.
   - Values for the entity delivering the response must be entered as a positive number.
   - Values between entities must sum to zero.

7) Contingent Balancing Authority Adjustment:
   - Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
   - Data for Value B is usually 0 MW, but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

FRI - NERC Frequency Response Initiative

The FRI Report made recommendations to evaluate Primary Frequency Response at additional time intervals during the event recovery period.
Additional evaluations have been added to both Form 1 and Form 2 to evaluate PFR delivery for these suggested time periods.
These evaluations utilize Interconnection frequency at specific times during the recovery period and calculates the BA's delivery of PFR for each selection.
These evaluations are not part of BAL-003 and will not impact compliance to R1 of the draft standard.
The following time selections are evaluated: T+46, T+76, T+106, T+136 and T+166.
Each evaluation is a P.U. measure based on the BA's Bias setting at each of these times.
Performance is the "best" performance at the specific time through 10 seconds past each time.
This is intended to account for any delay in data in the measurement. This measurement may be changed as experience in this effort increases.

Also included is the measure of PFR delivery during the T+20 to T+52 second period, the same as R1 of the standard.
The measure (P.U.) here is based on the BA Bias setting and not the FRO. This was done to provide comparison to the additional measurement times.

Some basic observations from this data:

1) If the P.U. value is close to 1.0, the BA delivered the full amount of PFR equal to its Bias setting.
2) The average performance of the Eastern Interconnection in PFR is about 40% of the total Interconnection Bias setting. If the BA's average score is greater than 0.40 P.U. then they are providing more PFR than the average BA. If the P.U. is less than 40% then they are providing less than average PFR.
3) If the P.U. value at T+46 is consistently less than the P.U. value at T+20 to T+52, then the PFR of the BA is not being sustained.
4) If the P.U. value at later time interval measures is consistently less, then withdrawal of PFR is occurring at a slower rate, but still being withdrawn.
5) If the P.U. value at T+20 to T+52, T+46, or T+76 is consistently greater than 1.0, this indicates that the BA Bias setting is too low.

Balancing Authority Name: MyBA

MyBA_091012_0227_FRS_Form2.9.xlsm

Interconnection Prevailing UFLS First Step Relay trip point 59.500 Hz

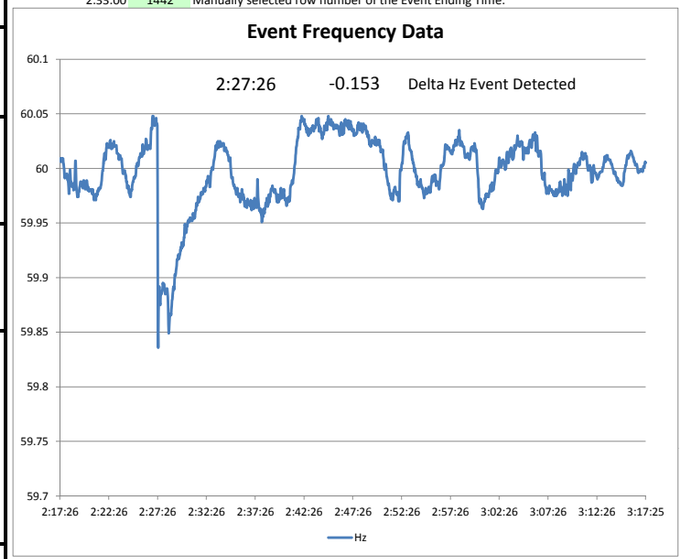
Interconnection High Relay trip point 60.500 Hz

004414

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**	
2:27:26	1245	Manually selected row number of the Event Starting Time.	Auto
2:33:00	1442	Manually selected row number of the Event Ending Time.	Manual

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



09/10/12 Date yymmdd

2:27 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

MyBA_091012_0227_FRS_Form2.9.xlsm

Date:	Monday, October 12, 2009
Time of T(0)	2:27:26
Time of Frequency Recovery to 60 Hz or Pre-Perturbation Hz	2:33:00
Value A Pre-Perturbation Average Frequency [T(-2) to T(-16)]	60.042 Hz
Value B Post-Perturbation Average Frequency [T(+20 to T(+52)]	59.889 Hz
Pre to Post Perturbation Delta Frequency Actual	-0.153 Hz
Value A Pre-Perturbation Average Interchange MW [T(-2) to T(-16)]	3645.73 MW

163.55 Interchange Target Relative Average Change - MW (Low Frequency Event)
123.97 Interchange Actual Relative Average Change - MW (Low Frequency Event)
No Interchange Actual Average minus MW @ T(-4) less than zero
Yes Interchange Average MW minus MW @ T(-4) greater than zero
Yes Interchange Target MW Average minus MW @ T(-4) greater than zero
60.52 Interchange Target Relative Average Change - MW (High Frequency Event)
20.94 Interchange Actual Relative Average Change - MW (High Frequency Event)
Up Ramp Direction during frequency recovery period

EPFR = Expected Primary Frequency Response EPFR(Final) 142.20 MW
MW Response in right direction for frequency delta Yes

Initial Response P.U. Performance 1.109 P.U.
0.758 P.U. Sustianed Response P.U. Performance

Date:	Monday, October 12, 2009
Time of T(0)	2:27:26
Time of Frequency Recovery to 60 Hz or Pre-Perturbation Hz	2:33:00
Value A Pre-Perturbation Average Frequency [T(-2) to T(-16)]	60.042 Hz
Value B Post-Perturbation Average Frequency [T(+20 to T(+52)]	59.889 Hz
Pre to Post Perturbation Delta Frequency Actual	-0.153 Hz
Value A Pre-Perturbation Average Interchange MW [T(-2) to T(-16)]	3645.73 MW
Value B Post-Perturbation Average Interchange MW [T(+20 to T(+52)]	3803.35 MW
Pre to Post Perturbation Interchange Delta MW Actual	157.63 MW
EPFR Pre-Perturbation Average	-43.39 MW
EPFR Post-Perturbation Average	114.21 MW
EPFR Unadjusted	157.60 MW
EPFR Adjusted	198.04 MW
Pre JOU Dynamic Schedules MW	350.00 MW
Pre Non-Conforming Load MW	165.34 MW
Pre Pumped Hydro MW	0.00 MW
Pre Transferred Frequency Response MW	-4.21 MW
Pre Contingent BA Lost Generation MW	15.00 MW
Sum of Pre Perturbation Adjustments	526.12 MW
Post JOU Dynamic Schedules MW	335.00 MW
Post Non-Conforming Load MW	214.13 MW
Post Pumped Hydro MW	6.35 MW
Post Transferred Frequency Response MW	11.09 MW
Post Contingent BA Lost Generation MW	0.00 MW
Sum of Post Perturbation Adjustments	566.57 MW
Net Total Adjustments MW	40.45 MW

T(20) to T(52) Evaluation

Pre-Perturbation Bias Setting	-103.00 MW/0.1 Hz
Post-Perturbation Bias Setting	-103.00 MW/0.1 Hz
EPFR for Bias Setting Pre-Perturbation Average	-43.39 MW
EPFR for Bias Setting Post-Perturbation Average	114.21 MW
EPFR for Bias Setting Delta	157.60 MW
Primary Frequency Response Delivery % of Bias	100.02%
Pre-Perturbation BA Load	7651.3 MW
Post-Perturbation BA Load	7632.0 MW
Pre to Post Perturbation BA Load Change	-19.305 MW
Load Dampening Frequency Response	-12.617 MW/0.1 Hz
Load Dampening % of Total BA Frequency Response	12.25%
Average Bias Setting when Hz is greater than +/-0.036 Hz	-103.00 MW/0.1 Hz

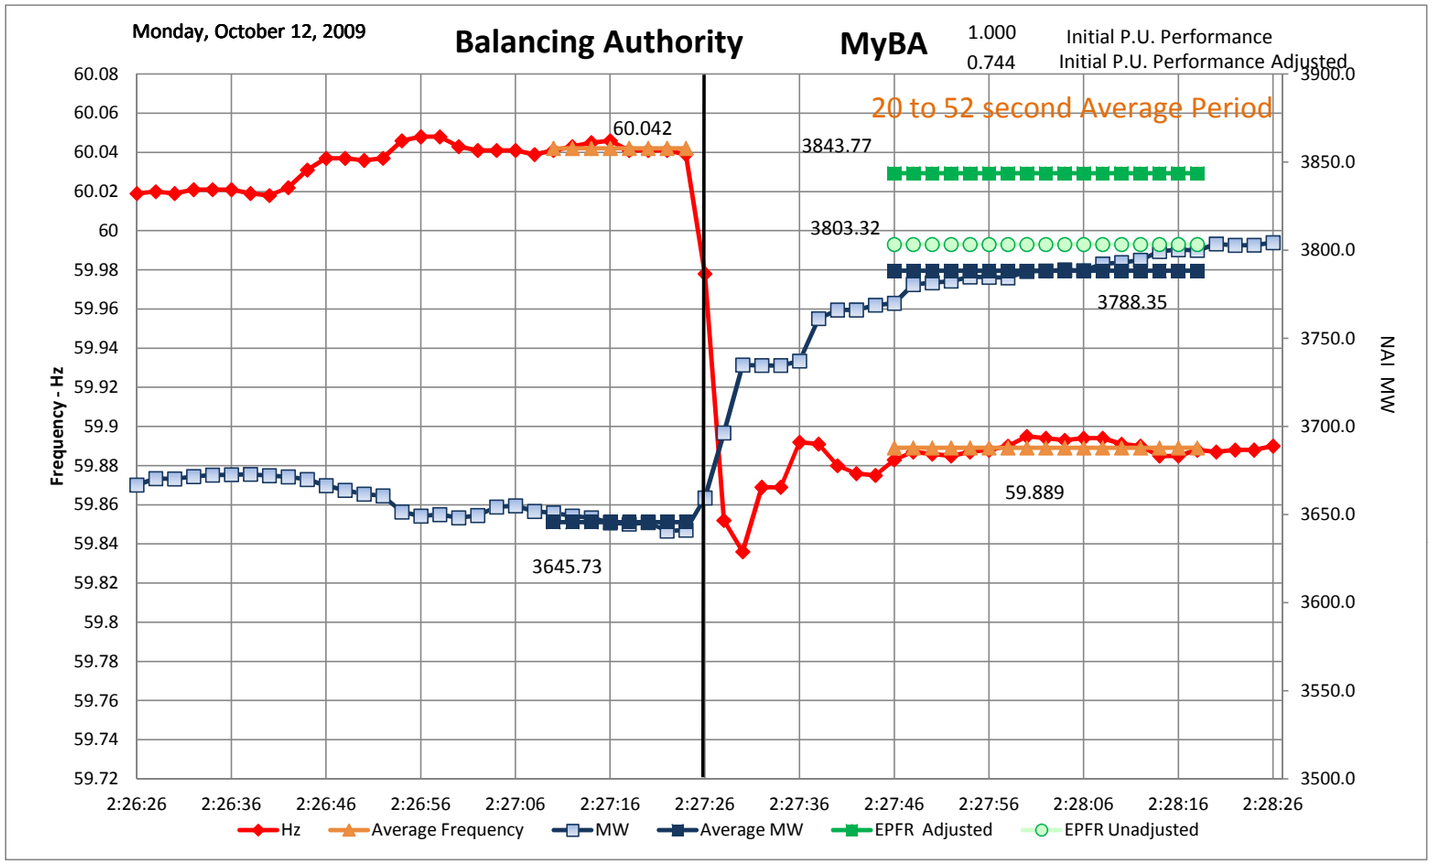
004418



T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

004419

# of rows to shift T(0)

1

A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps	To be completed for each event evaluated.	
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:	
	Column A: Date and Time in this format, mm/dd/yy HH:MM:SS	004424
	Column B: Frequency Hz	
	Column C: Net Actual Interchange	
	Column D: Joint Owned Unit dynamic schedule	
	Column E: Non Conforming Load	
	Column F: Pumped Hydro	
	Column G: Not Used	
	Column H: Transferred Frequency Response	
	Column I: Contingent BA Lost load or generation	
	Column J: BA Bias Setting	
	Column K: BA Load	
2	Note: Columns D, E, F and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.	
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.	
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data.	
	Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.	
	If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.	
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet.	
	If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should	
	you have to use the "Manual" process.	
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary.	
	To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).	
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.	
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events)	
	This value controls the end of the "Sustained Frequency Response" evaluation period.	
	Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.	
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized	
	in the correct order on worksheet "Form 1 Summary Data".	
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.	
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.	

Steps	To be completed the first time you use Form 2 for your BA.
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "NYISO".
B	For informational and educational purposes, a "Sustained" performance evaluation is provided in the "Evaluation" worksheet and in the "Sustained" Graph. This evaluation uses a Time Constant (TC) to model the frequency response of your BA
	The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35.
	The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0.
	This time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO.
	A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines.
	By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar to the slope of the NAI data.
	When set appropriately, the "Target" trend on the "Sustained" graph will model what the Net Actua Interchange should have done during the event recovery period based on your Bias setting during the event.

MyBA

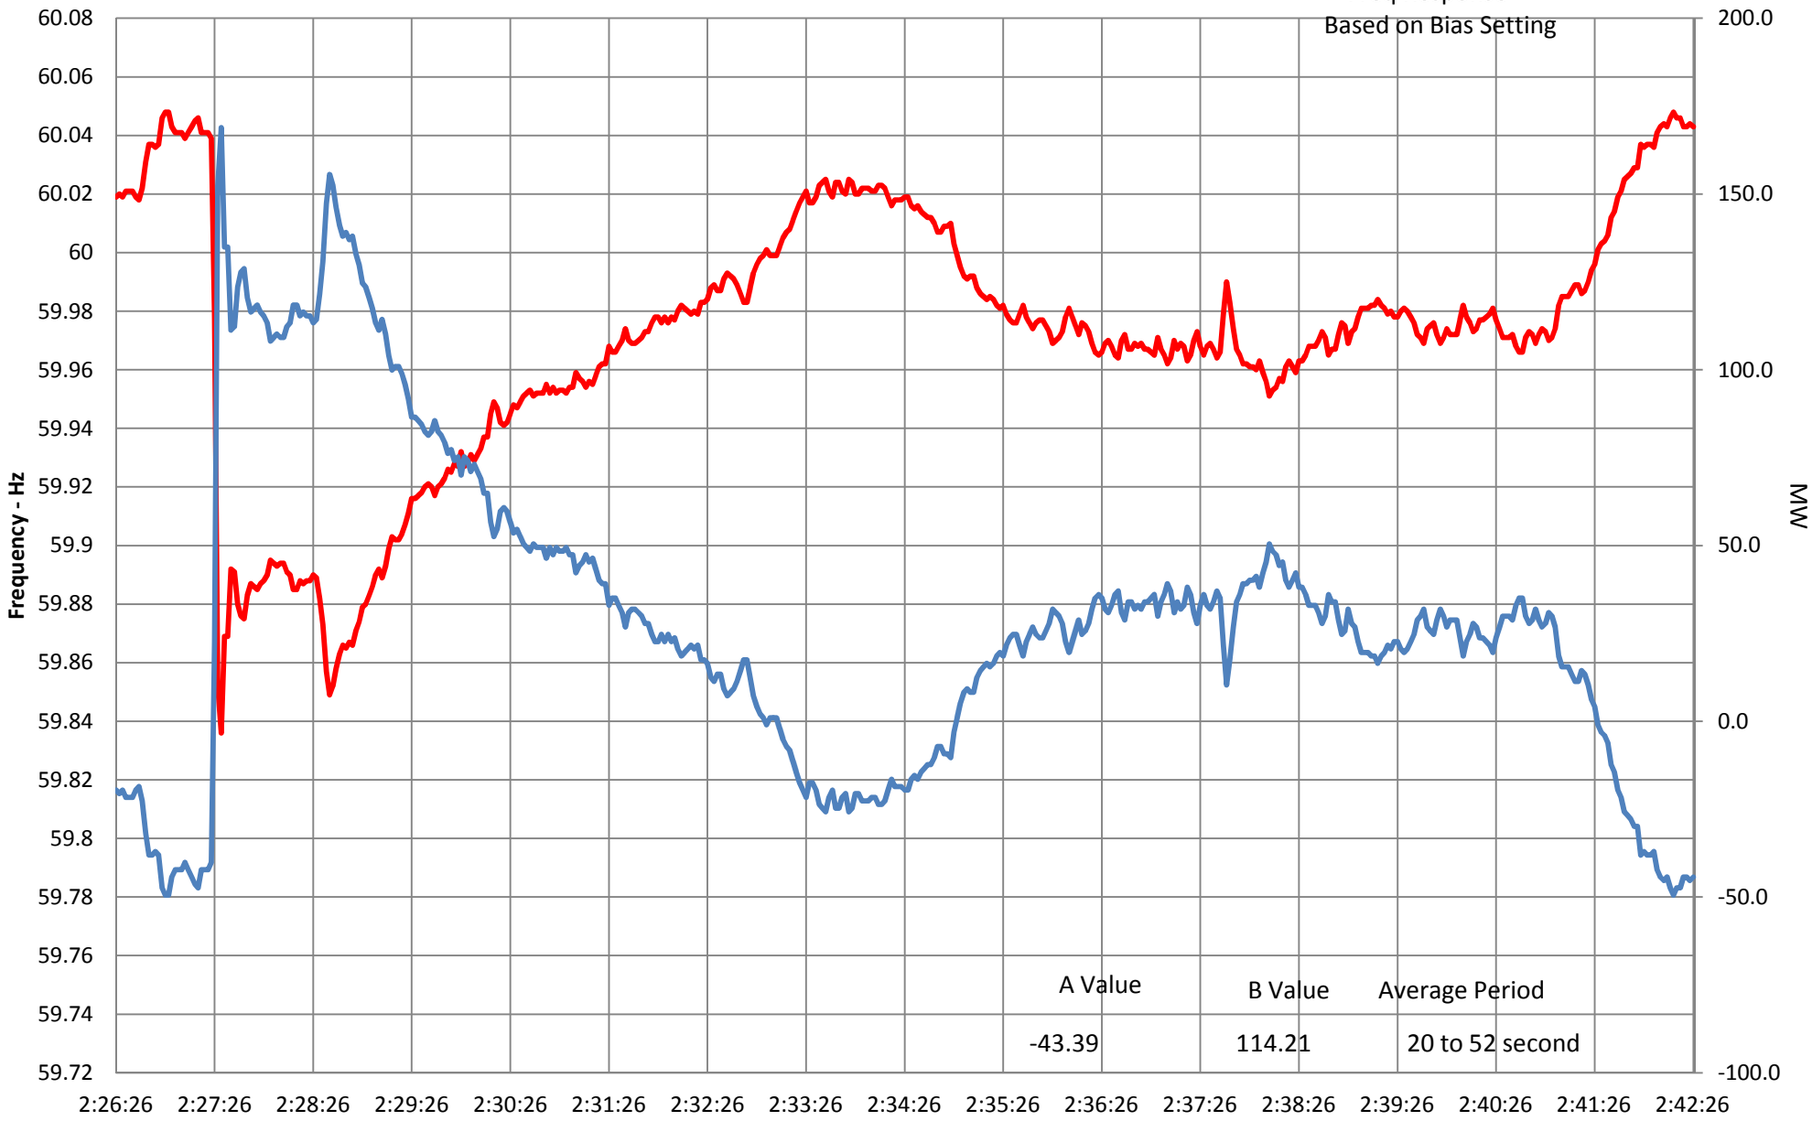
Expected Primary
Freq Response
Based on Bias Setting



Steps	To be completed for each event evaluated.
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order: Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Contingent Resouce Lost MW or Lost Load Column D: Load Resources tripped during the event. Column E: Non Conforming Load Column F: Spare Column G: Not Used Column H: Spare Column I: Spare Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time. If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period. Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is sum in the correct order on worksheet "Form 1 Summary Data".
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps	To be completed the first time you use Form 2 for your BA.
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Balancing Authority Name: MyBA

MyBA_091012_0227_FRS_Form2.9.xlsm

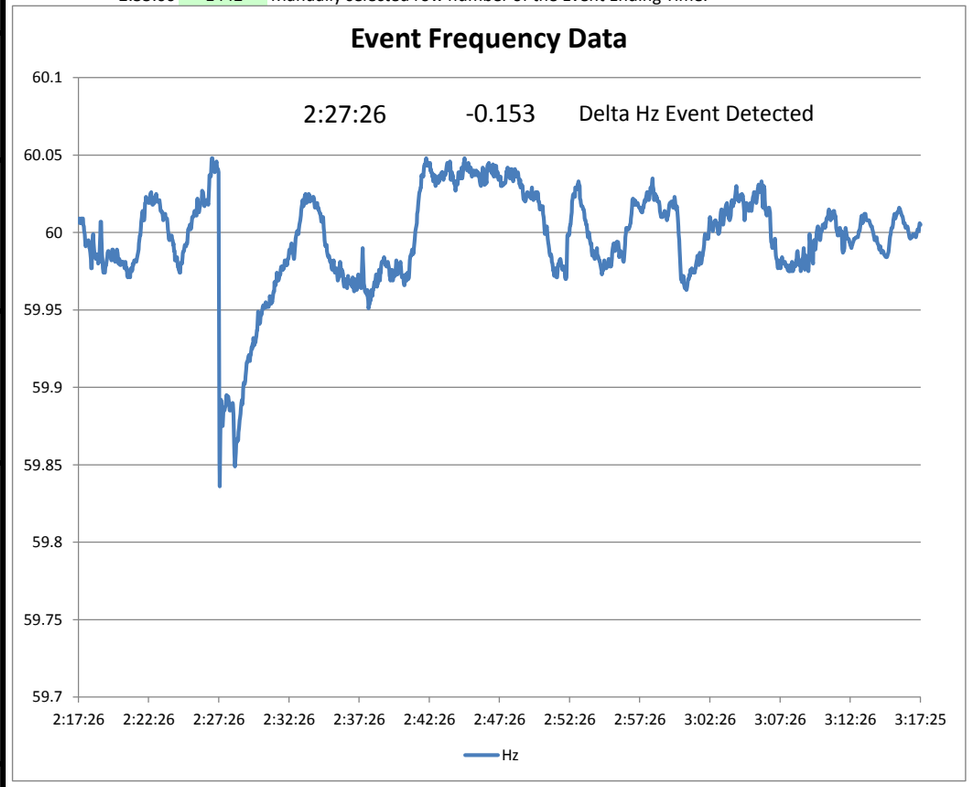
Interconnection Prevailing UFLS First Step Relay trip point 59.500 Hz

Interconnection High Relay trip point 60.500 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**
2:27:26	1245	Manually selected row number of the Event Starting Time.
2:33:00	1442	Manually selected row number of the Event Ending Time.

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



09/10/12 Date yymmdd

2:27 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

MyBA_091012_0227_FRS_Form2.9.xlsm

T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

# of rows to shift T(0)

1

A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps	**To be completed for each event evaluated.**
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order: Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Net Actual Interchange Column D: Joint Owned Unit dynamic schedule Column E: Non Conforming Load Column F: Pumped Hydro Column G: Not Used Column H: Transferred Frequency Response Column I: Contingent BA Lost load or generation Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D, E, F and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time. If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period. Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps	**To be completed the first time you use Form 2 for your BA.**
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "NYISO".
B	For informational and educational purposes, a "Sustained" performance evaluation is provided in the "Evaluation" worksheet and in the "Sustained" Graph. This evaluation uses a Time Constant (TC) to model the frequency response of your BA. The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35. The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0. This time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO. A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines. By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar to the slope of the NAI data. When set appropriately, the "Target" trend on the "Sustained" graph will model what the Net Actua Interchange should have done during the event recovery period based on your Bias setting during the event.

Balancing Authority Name: MyBA

MyBA_110516_0806_FRS_Form2.9.xlsm

Interconnection Prevailing UFLS First Step Relay trip point 59.300 Hz

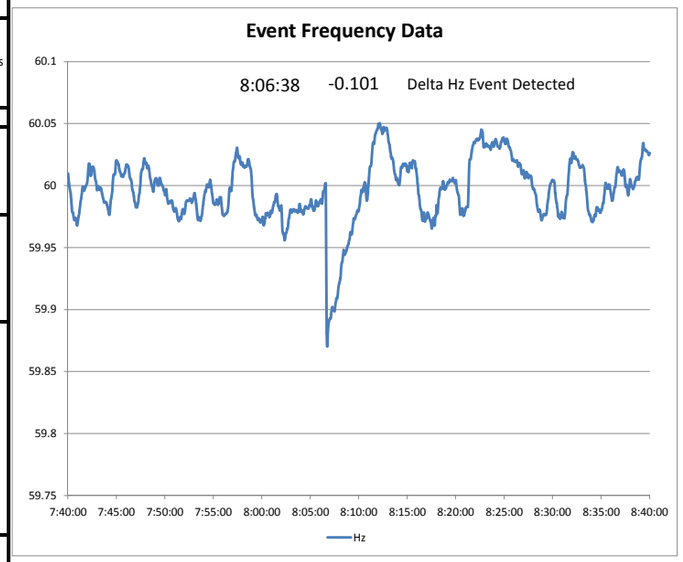
Interconnection High Relay trip point 60.700 Hz

004584

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**	Auto
8:06:38	1245	Manually selected row number of the Event Starting Time.	Manual
8:10:30	1442	Manually selected row number of the Event Ending Time.	

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



11/05/16 Date yymmdd

8:06 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

"Auto" Event Detection adjustment of T(0). 004589
# of rows to shift T(0)
1
A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps	To be completed for each event evaluated.
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Contingent Resouce Lost MW or Lost Load Column D: Load Resources tripped during the event. Column E: Non Conforming Load Column F: Spare Column G: Not Used Column H: Spare Column I: Spare Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" workshee If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0)
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz event This value controls the end of the "Sustained Frequency Response" evaluation period Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarize in the correct order on worksheet "Form 1 Summary Data"
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC

Steps	To be completed the first time you use Form 2 for your BA.
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT"

Balancing Authority Name: MyBA

MyBA_110516_0806_FRS_Form2.9.xlsm

004650

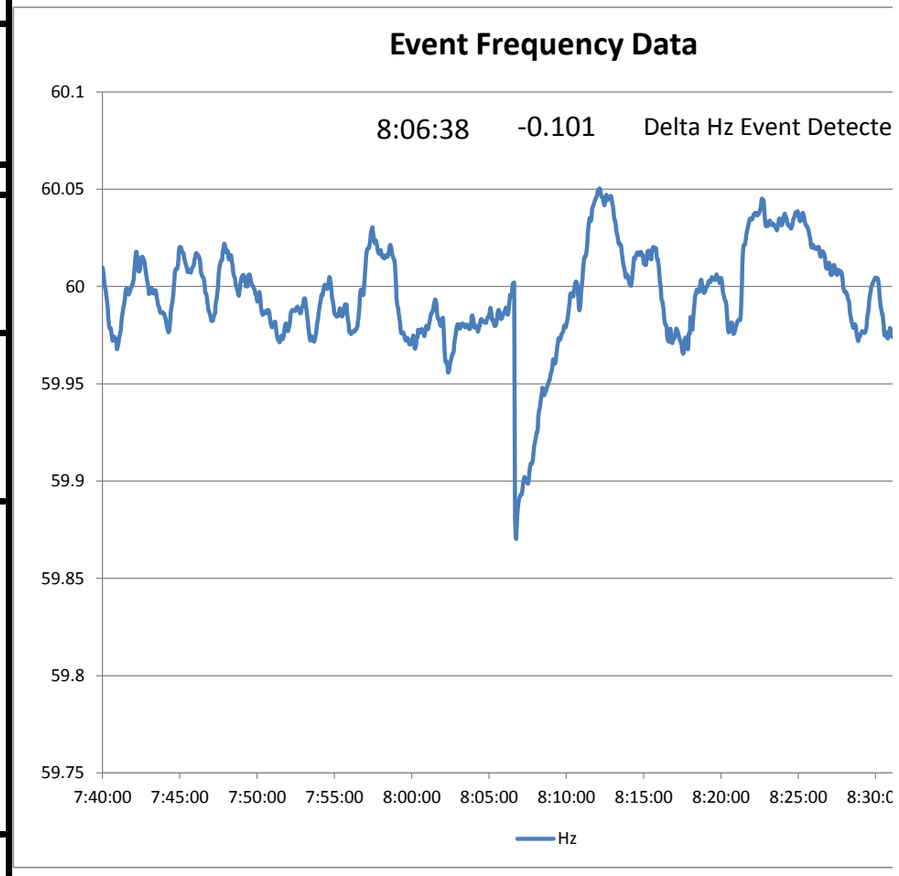
Interconnection Prevailing UFLS First Step Relay trip point 58.500 Hz

Interconnection High Relay trip point 61.500 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**
8:06:38	1245	Manually selected row number of the Event Starting Time.
8:10:30	1442	Manually selected row number of the Event Ending Time.

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



11/05/16 Date yymmdd

8:06 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

MyBA_110516_0806_FRS_Form2.9.xlsm

Date:	Monday, May 16, 2011

T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

"Auto" Event Detection adjustment of T(0).
# of rows to shift T(0)
1
A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps **To be completed for each event evaluated.**

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Column A: Date and Time in this format, mm/dd/yy HH:MM:SS
Column B: Frequency Hz
Column C: Contingent Resouce Lost MW or Lost Load
Column D: Load Resources tripped during the event.
Column E: Non Conforming Load
Column F: Spare
Column G: Not Used
Column H: Spare
Column I: Spare
Column J: BA Bias Setting
Column K: BA Load

2 Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.

3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.

4 Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data.
Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.

5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet.
If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.

6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary.
To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).

7 If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.

8 The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events)
This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.

9 Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".

10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.

11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps **To be completed the first time you use Form 2 for your BA.**

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Expected Primary Freq Response Based on Bias Setting

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Standards Announcement

Project 2007-12 Frequency Response

Recirculation Ballot is now open through 8 p.m. Friday, December 21, 2012

Now Available

A recirculation ballot window for **BAL-003-1 – Frequency Response and Frequency Bias Setting** is now open through **8 p.m. Eastern on Friday, December 21, 2012.**

The Frequency Response Standard Drafting Team did not make any substantive changes to the documents, but did make the following minor changes based on stakeholder comments:

- Made clarifying changes to the proposed standard including replacing the term "…subject to…" with "…in accordance with…" in Requirement R2.
- Clarified the description of the calculation for the Interconnection IFRO in Attachment A.
- Modified Attachment A and the Procedure to provide consistency with the use of the term "resource contingency criteria."
- Corrected typographical errors in all documents.

Instructions

In the recirculation ballot, votes are counted by exception. Only members of the ballot pool may cast a ballot; all ballot pool members may change their previously cast votes. A ballot pool member who failed to cast a ballot during the last ballot window may cast a ballot in the recirculation ballot window. If a ballot pool member does not participate in the recirculation ballot, that member's vote cast in the previous ballot will be carried over as that member's vote in the recirculation ballot.

Members of the ballot pool associated with this project may log in and submit their vote for the standard by clicking here.

Next Steps

Voting results will be posted and announced after the ballot window closes. If approved, the standard will be submitted to the Board of Trustees for adoption and then filed with the appropriate regulatory authorities.

Background

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. There is evidence of continuing

decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard would set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation.

Additional information is available on the project page.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Wendy Muller, Standards Development Administrator, at wendy.muller@nerc.net or at 404-446-2560.
