Steps	**To be completed for each event evaluated.**
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order: Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Net Actual Interchange Column D: Joint Owned Unit dynamic schedule Column E: Non Conforming Load Column F: Pumped Hydro Column G: Not Used Column H: Transferred Frequency Response Column I: Contingent BA Lost load or generation Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D, E, F and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time. If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period. Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps	**To be completed the first time you use Form 2 for your BA.**
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "NYISO".
B	For informational and educational purposes, a "Sustained" performance evaluation is provided in the "Evaluation" worksheet and in the "Sustained" Graph. This evaluation uses a Time Constant (TC) to model the frequency response of your BA. The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35. The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0. This time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO. A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines. By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar to the slope of the NAI data. When set appropriately, the "Target" trend on the "Sustained" graph will model what the Net Actua Interchange should have done during the event recovery period based on your Bias setting during the event.

Balancing Authority Name: MyBA

MyBA_110516_0806_FRS_Form2.9.xlsm

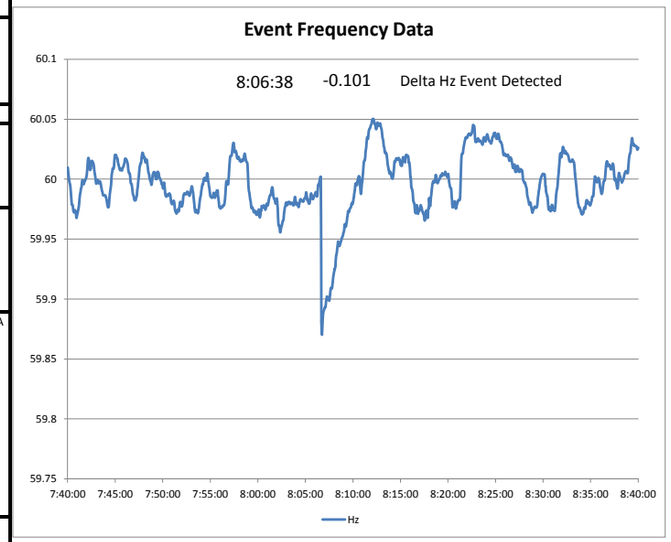
Interconnection Prevailing UFLS First Step Relay trip point 59.300 Hz

Interconnection High Relay trip point 60.700 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	Event Detection	Auto
8:06:38	1245	Manually selected row number of the Event Starting Time.	Manual
8:10:30	1442	Manually selected row number of the Event Ending Time.	

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



11/05/16 Date yymmdd

8:06 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

MyBA_110516_0806_FRS_Form2.9.xlsm

Date:	Monday, May 16, 2011	
Time of T(0)	8:06:38	
Time of Frequency Recovery to 60 Hz or Pre-Perturbation Hz	8:10:30	
Value A Pre-Perturbation Average Frequency [T(-2) to T(-16)]	59.999	Hz

Yes	Interchange Actual Average minus MW @ T(-4) less than zero
No	Interchange Average MW minus MW @ T(-4) greater than zero
Yes	Interchange Target MW Average minus MW @ T(-4) greater than zero
146.62	Interchange Target Relative Average Change - MW (High Frequency Event)
-470.90	Interchange Actual Relative Average Change - MW (High Frequency Event)
Down	Ramp Direction during frequency recovery period

EPFR = Expected Primary Frequency Response — EPFR(Final) 662.51 MW

MW Response in right direction for frequency delta — Yes

Initial Response P.U. Performance 0.711 P.U. — 0.738 P.U. Sustained Response P.U. Performance

"Auto" Event Detection adjustment of T(0).
# of rows to shift T(0)
1
A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

Steps **To be completed for each event evaluated.**

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Column A: Date and Time in this format, mm/dd/yy HH:MM:SS
Column B: Frequency Hz
Column C: Contingent Resouce Lost MW or Lost Load
Column D: Load Resources tripped during the event.
Column E: Non Conforming Load
Column F: Spare
Column G: Not Used
Column H: Spare
Column I: Spare
Column J: BA Bias Setting
Column K: BA Load

2 Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.

3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.

4 Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data.
Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.

5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet.
If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.

6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary.
To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).

7 If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.

8 The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events)
This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.

9 Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".

10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.

11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps **To be completed the first time you use Form 2 for your BA.**

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Balancing Authority Name: MyBA

MyBA_110516_0806_FRS_Form2.9.xlsm

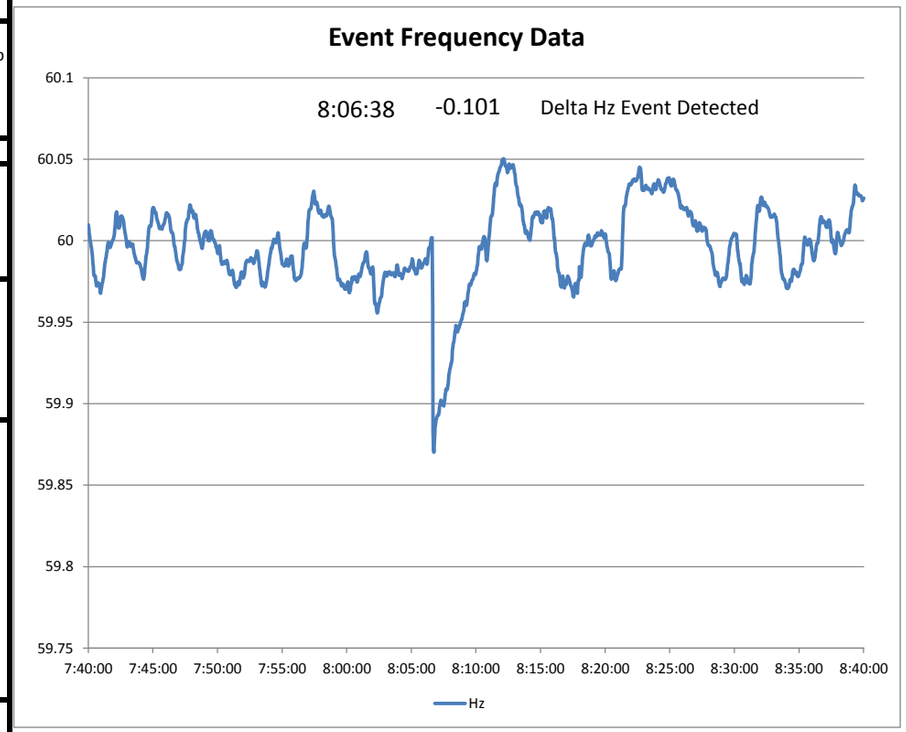
Interconnection Prevailing UFLS First Step Relay trip point 58.500 Hz

Interconnection High Relay trip point 61.500 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**
8:06:38	1245	Manually selected row number of the Event Starting Time.
8:10:30	1442	Manually selected row number of the Event Ending Time.

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



11/05/16 Date yymmdd

8:06 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

MyBA_110516_0806_FRS_Form2.9.xlsm

T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

"Auto" Event Detection adjustment of T(0).
# of rows to shift T(0)
1
A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps	**To be completed for each event evaluated.**
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order: Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Contingent Resouce Lost MW or Lost Load Column D: Load Resources tripped during the event. Column E: Non Conforming Load Column F: Spare Column G: Not Used Column H: Spare Column I: Spare Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time. If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period. Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps	**To be completed the first time you use Form 2 for your BA.**
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Balancing Authority Name: MyBA

MyBA_091012_0227_FRS_Form2.9.xlsm

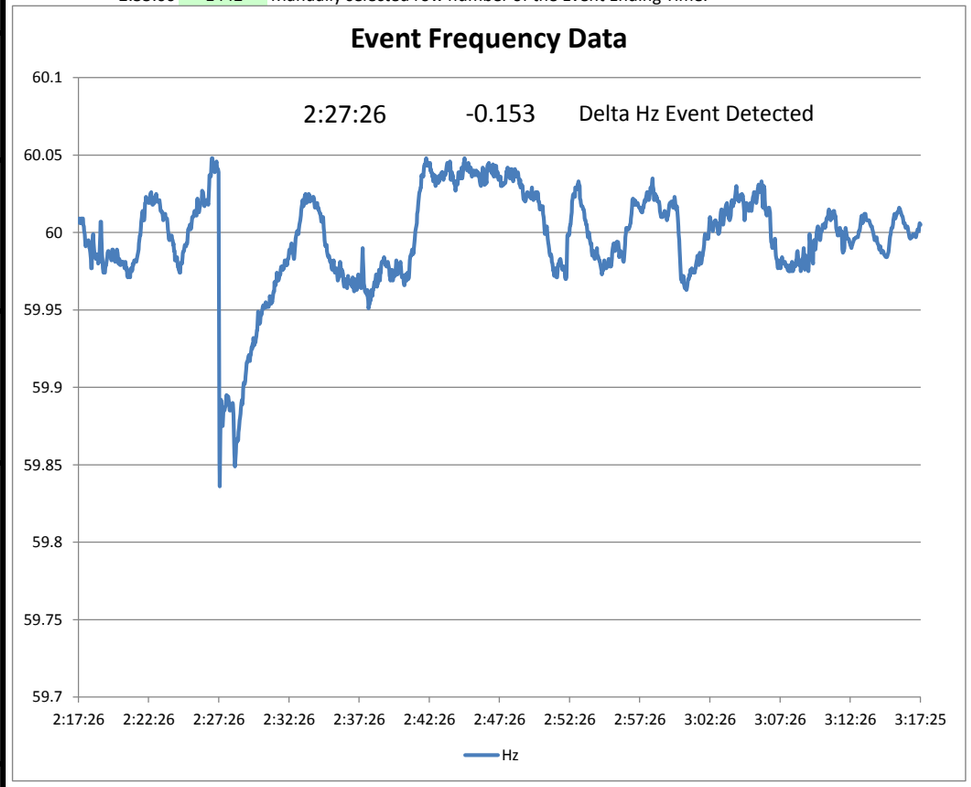
Interconnection Prevailing UFLS First Step Relay trip point 59.500 Hz

Interconnection High Relay trip point 60.500 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**
2:27:26	1245	Manually selected row number of the Event Starting Time.
2:33:00	1442	Manually selected row number of the Event Ending Time.

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



09/10/12 Date yymmdd

2:27 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

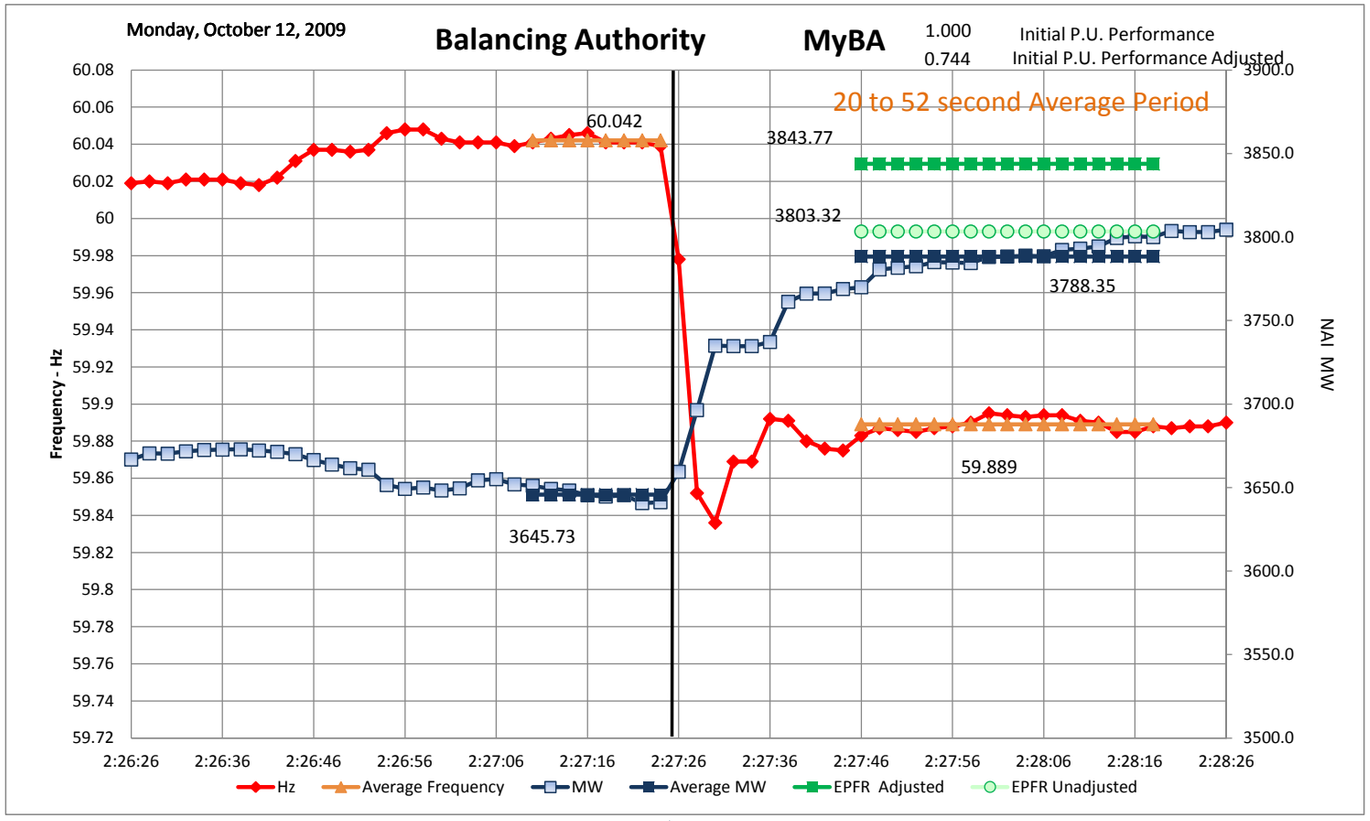
Adjusted P.U. Performance
0.856
0.808
0.829
0.633
0.689



T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

# of rows to shift T(0)

1

A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps	**To be completed for each event evaluated.**
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order: Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Net Actual Interchange Column D: Joint Owned Unit dynamic schedule Column E: Non Conforming Load Column F: Pumped Hydro Column G: Not Used Column H: Transferred Frequency Response Column I: Contingent BA Lost load or generation Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D, E, F and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time. If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period. Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps	**To be completed the first time you use Form 2 for your BA.**
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "NYISO".
B	For informational and educational purposes, a "Sustained" performance evaluation is provided in the "Evaluation" worksheet and in the "Sustained" Graph. This evaluation uses a Time Constant (TC) to model the frequency response of your BA. The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35. The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0. This time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO. A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines. By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar to the slope of the NAI data. When set appropriately, the "Target" trend on the "Sustained" graph will model what the Net Actua Interchange should have done during the event recovery period based on your Bias setting during the event.

Balancing Authority Name: MyBA

MyBA_110516_0806_FRS_Form2.9.xlsm

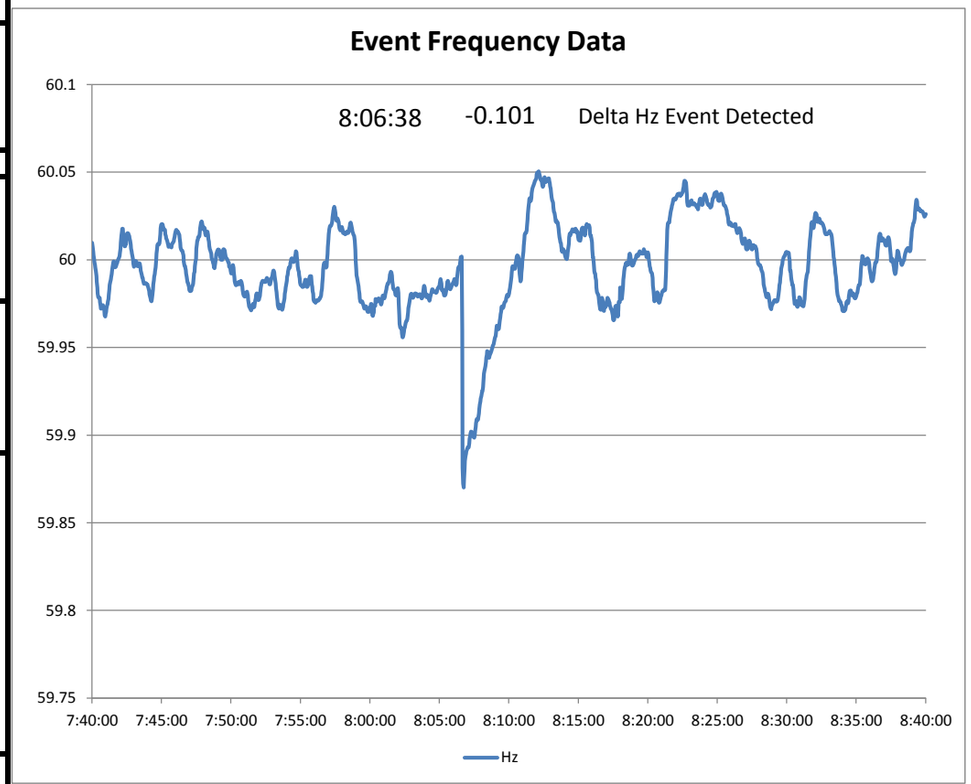
Interconnection Prevailing UFLS First Step Relay trip point 59.300 Hz

Interconnection High Relay trip point 60.700 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	**Event Detection**
8:06:38	1245	Manually selected row number of the Event Starting Time.
8:10:30	1442	Manually selected row number of the Event Ending Time.

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



11/05/16 Date yymmdd

8:06 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

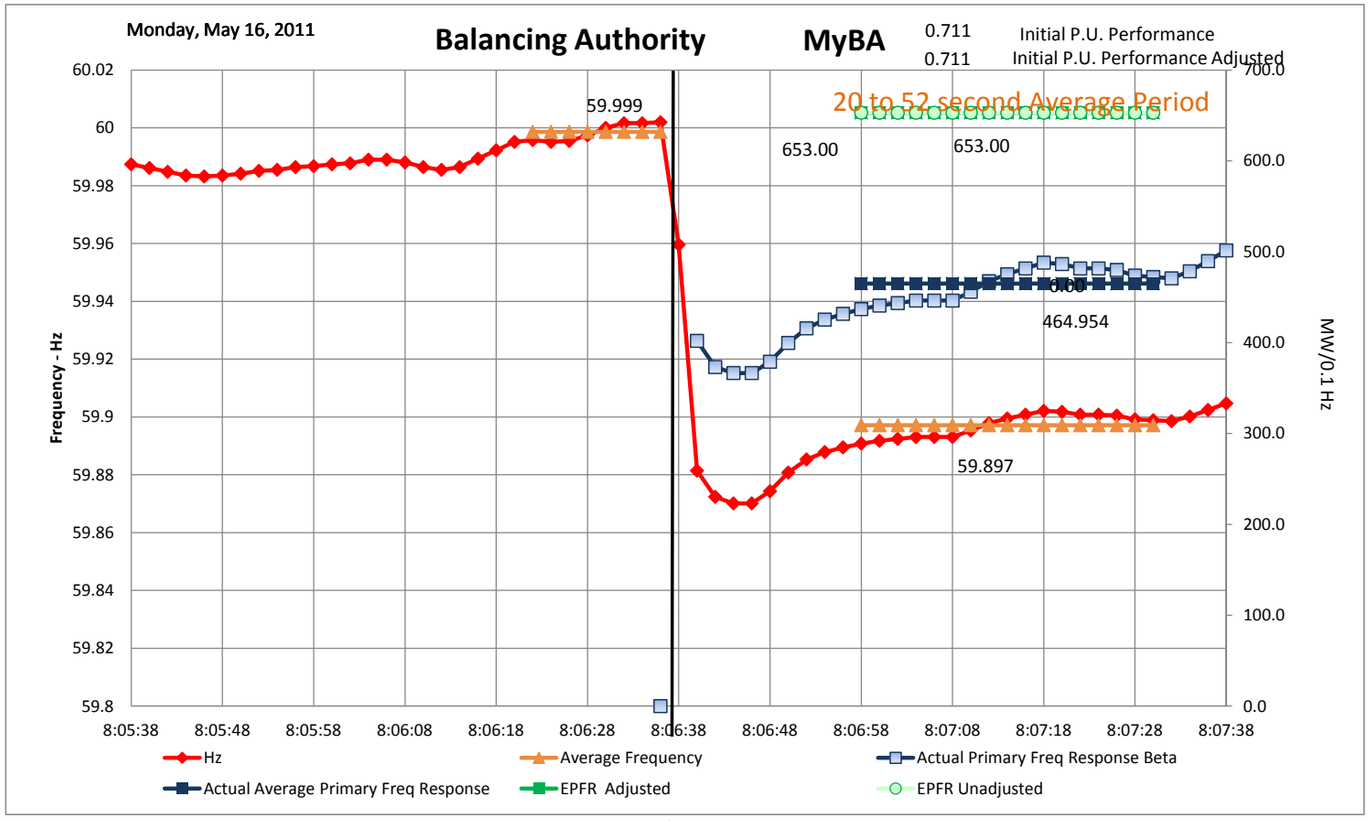
Adjusted P.U. Performance
0.738
0.860
1.323
1.532
2.309



T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

"Auto" Event Detection adjustment of T(0).
# of rows to shift T(0)
1
A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps	**To be completed for each event evaluated.**
1	Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order: Column A: Date and Time in this format, mm/dd/yy HH:MM:SS Column B: Frequency Hz Column C: Contingent Resouce Lost MW or Lost Load Column D: Load Resources tripped during the event. Column E: Non Conforming Load Column F: Spare Column G: Not Used Column H: Spare Column I: Spare Column J: BA Bias Setting Column K: BA Load
2	Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3	Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4	Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time. If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6	Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).
7	If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8	The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period. Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9	Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".
10	Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11	Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps	**To be completed the first time you use Form 2 for your BA.**
A	Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Balancing Authority Name: MyBA

MyBA_110516_0806_FRS_Form2.9.xlsm

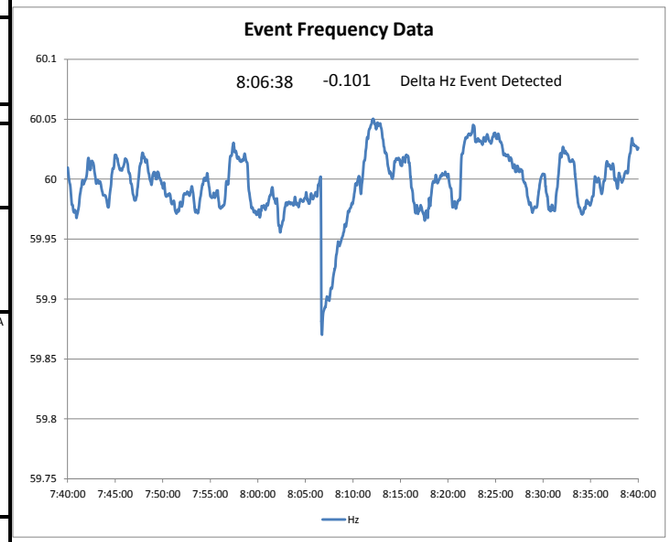
Interconnection Prevailing UFLS First Step Relay trip point 58.500 Hz

Interconnection High Relay trip point 61.500 Hz

Note: See "Instruction" tab for more detailed instructions.

	Auto	Event Detection	Auto
8:06:38	1245	Manually selected row number of the Event Starting Time.	Manual
8:10:30	1442	Manually selected row number of the Event Ending Time.	

Step 1.	Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss.
Step 2.	**Data must start at least 2 full minutes before the beginning of the event.** Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well.
Step 3.	Enter your BA name in cell B1 of this worksheet.
Step 4.	Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
Step 5.	Verify that the "Auto" selection of T(0) is correct by observing "Graph 20 to 52s". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for T(0) alignment is provided in Cell Q3 on the Graph 20 to 52s.
Step 6.	When T(0) is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. Copy Form 2 data for Pasting into Form 1
Step 7.	Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9.
Step 8.	Save this workbook using the following file name in bold below:



11/05/16 Date yymmdd

8:06 Time hh:ss of T(0)

Where "MyBA" = your BA mnemonic

T(0)

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph.
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

"Auto" Event Detection adjustment of T(0).
# of rows to shift T(0)
1
A zero value aligns the data to the hightest Frequency change value.
Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting.
For BAs that utilize a variable Bias, the Bias average during T(+20) to T(+52) is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response.
P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

Steps **To be completed for each event evaluated.**

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Column A: Date and Time in this format, mm/dd/yy HH:MM:SS
Column B: Frequency Hz
Column C: Contingent Resouce Lost MW or Lost Load
Column D: Load Resources tripped during the event.
Column E: Non Conforming Load
Column F: Spare
Column G: Not Used
Column H: Spare
Column I: Spare
Column J: BA Bias Setting
Column K: BA Load

2 Note: Columns D & E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.

3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.

4 Data must start a **minimum** of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data.
Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.

5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet.
If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.

6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52s" worksheet. Adjust the selection if necessary.
To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52s" worksheet. Usually a 0, 1 or 2 will achive the correct alignment of T(0).

7 If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.

8 The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz, whichever is lower. (for low Hz events)
This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.

9 Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".

10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.

11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2s with your Form 1 to NERC.

Steps **To be completed the first time you use Form 2 for your BA.**

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Standards Announcement

Project 2007-12 Frequency Response

Successive Ballot and Non-Binding Poll Open Through 8 p.m. Monday, November 5, 2012

Now Available

A successive ballot of **BAL-003-1 – Frequency Response and Frequency Bias Setting** and a non-binding poll of the associated VRFs/VSLs is open through **8 p.m. Eastern on Monday, November 5, 2012.**

Instructions

Members of the ballot pools associated with this project may log in and submit their vote for the Standard and opinion in the non-binding poll of the associated VRFs and VSLs by clicking here.

Please read carefully: All stakeholders with comments (both members of the ballot pool as well as other stakeholders, including groups such as trade associations and committees) must submit comments through the electronic comment form. During the ballot window, balloters who wish to submit comments with their ballot *may no longer enter comments on the balloting screen*, but may still enter the comments through the electronic comment form. Balloters who wish to express support for comments submitted by another entity or group will have an opportunity to enter that information and are not required to answer any other questions.

Next Steps

The drafting team will consider all comments received during the formal comment period and successive ballot and, if needed, make revisions to the standards. If the comments do not show the need for significant revisions, the standard will proceed to a recirculation ballot.

Background

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The proposed standard's intent is to collect data needed to accurately analyze existing Frequency Response, set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be analyzed, and the reasons for the decline in Frequency Response

can be identified. Once Frequency Response has been analyzed and confirmed, requirements can be modified to maintain reliability.

Additional information is available on the project page.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson, Standards Development Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-12 Frequency Response

Formal Comment Period Open:	October 5, – November 5, 2012
Upcoming: **Successive Ballot and Non-binding Polls:**	**October 26 – November 5, 2012**

Now Available

BAL-003-1 – Frequency Response and Frequency Bias Setting, an implementation plan and several associated documents (listed below) have been posted for a parallel formal comment period and successive ballot through **8 p.m. Eastern on Monday, November 5, 2012.**

The following associated documents have been posted for stakeholder review and comment:

- **Frequency Response Standard Background Document** – Provides an explanation of each of the proposed requirements; identifies how the proposed standard proposes to address FERC directives from Order 693; and describes the decision process for use of the median as the measure for Frequency Response.
- **Attachment A** – Provides methodology for calculating Interconnection Frequency Response Obligation, Balancing Authority Frequency Response Obligation, Frequency Response Measure and the Frequency Bias Setting.
- **Procedure** – Assigns tasks to the ERO and provides instructions for the ERO to follow when carrying them out to support the BAL-003-1 standard.
- **FRS Form 1 (three versions – multiple Balancing Authority Interconnection, ERCOT and Quebec) and FRS Form 2 (three versions – multiple Balancing Authority Interconnection, ERCOT and Quebec)** used to determine each Balancing Authority's Frequency Response Measure and Frequency Bias Setting. Instructions are now on the first page of each FRS Form 1 and FRS Form 2.
- **Mapping Document** – Identifies each requirement in the already approved BAL-003-0.1b and identifies how that requirement has been treated in the revisions proposed in BAL-003-1.

Instructions for Commenting

A formal comment period is open through **8 p.m. Eastern on Monday, November 5, 2012**. Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Wendy Kinnard at wendy.kinnard@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page.

Please read carefully: All stakeholders with comments (both members of the ballot pool as well as other stakeholders, including groups such as trade associations and committees) must submit comments through the electronic comment form. During the ballot window, balloters who wish to submit comments with their ballot *may no longer enter comments on the balloting screen*, but may still enter the comments through the electronic comment form. Balloters who wish to express support for comments submitted by another entity or group will have an opportunity to enter that information and are not required to answer any other questions.

Next Steps

A successive ballot and non-binding polls of the associated VRFs and VSLs will be conducted Friday, October 26, 2012 through 8 p.m. Monday, November 5, 2012.

Background

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The proposed standard's intent is to collect data needed to accurately analyze existing Frequency Response, set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. Project 2007-12 Frequency Response

Successive Ballot and Non-Binding Poll Results

Now Available

A successive ballot of **BAL-003-1 – Frequency Response and Frequency Bias Setting** and a non-binding poll of the associated VRFs/VSLs concluded on **Tuesday, November 6, 2012.**

Voting statistics for each ballot are listed below, and the Ballots Results page provides a link to the detailed results.

Approval	Non-binding Poll Results
Quorum: 82.04%	Quorum: 76.28%
Approval: 76.08%	Supportive Opinions: 76.30 %

Next Steps

The drafting team will consider all comments received during the formal comment period and successive ballot and, if needed, make revisions to the standards. If the comments do not show the need for significant revisions, the standard will proceed to a recirculation ballot.

Background

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard would set a minimum Frequency Response obligation for each Balancing Authority, provide a uniform calculation of Frequency Response and Frequency Bias Settings that transition to values closer to natural Frequency Response, and encourage coordinated AGC operation.

Additional information is available on the project page.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

The ISO supports the development of BAL-003-1 and would like to offer the following comments/suggestions: (1) Some BAs may have to develop a new Ancillary Service product to ensure that its FRO can be met and believes that 12 months after FERC's approval may not provide adequate time to stakeholder and modify market software applications. The ISO suggest increasing the implementation timeline by at least one more year. (2) If the implementation timeline cannot be changed, then the ISO suggests that compliance should be waived for the first year of operation

under BAL-003-1. (3) Some BAs may elect to procure a portion of its FRO through bilateral agreements for certain hours (e.g. off-peak) with a neighboring BA. Since a contingency could be in a BA other than the two BAs under a bilateral agreement, the standard or background document needs to clarify the duration of frequency response so that transmission reservation is not a requirement for frequency response. The ISO believes that the BA experiencing the contingency should have adequate arrangements in place to deal with internal contingencies.

If a BA is using a frequency bias setting and is not providing Overlap Regulation Service (supplying actual interchange, frequency response, and schedules to another BA), then it can be assumed that the BA is supplying regulation service. Was the intent of the requirement to simply state that all BA's must have a bias setting less than zero at all times? The intent of this requirement needs to be clarified.
No
This document lacks definitions of terms such as CCadj, DFcc, DFcbr, resource contingency criteria (in the attachment, this is called the "target contingency criteria"), etc. A sample calculation would be of value to entities. "The largest category C (N-2) event is used for all interconnections except the Eastern which uses the largest event in the last 10 years". All interconnections should be using the same design basis contingency. The NERC 2012 CPS2 bounds has an Eastern Interconnection frequency bias of -6,360 MW/.1Hz. Why does this attachment refer to an Interconnection frequency response obligation of -1,002MW/.1Hz.? This is a significant difference.
No
While the discussion of primary frequency response includes inertial energy, the term inertial energy is missing from the definition of "primary frequency response".
No
The purpose of BAL-003 was to calculate frequency bias in the ACE equation used in BAL-001. The Standard is currently confusing to understand, and it is unclear how the bias is calculated. It is recommended that efforts should be made to clarify the changes, especially in Attachment A.
The VSL's refer to the FRM (Frequency Response Measure). If that is the intent of the Standard, then GO's and GOP's should be included in the applicability since they are the entities responding to the AGC signals. If the intent is the FRO (Frequency Response Obligation) only, then the VSL's should be updated.

EEI does not fully agree with the definition of a “Frequency Response Sharing Group” (FRSG). In the definition offered in the new Standard, it states that the FRSG “collectively maintain, allocate, and supply operating resources”. Of the three roles, a balancing authority only maintains load-interchange-generation balance through the allocation of resources. Therefore, EEI suggests that the definition be changed to more appropriately align with the role of a BA, which we believe would be to allocate resources in a manner that effectively allows the sharing of resources necessary to achieve a FRO within the defined sharing group, which might otherwise not be possible or practical by a BA on its own.
Yes
Yes
Yes
EEI supports the ERO’s role as defined in the procedure but is concerned that the procedure, unlike approved NERC standards, is unbounded by the current rules for developing standards. For that reason, EEI recommends that the procedure become more formalized and integrated into the standard as an addendum thereby avoiding any Industry concerns that future modification might occur outside the approved processes
Yes
EEI finds the method to be acceptable but as mentioned in our response to question No. 5 (above), we believe that the procedure should be more formally documented as an addendum. Such a change would ensure that the document would remain unchanged outside of the approved standards making process. Additionally, EEI does not support using 4500 MW loss as the basis for determining the FRO for the Eastern Interconnection for future events. However, as the calculation also includes 59.5 Hz as the basis for determining the FRO, the results is an allocation which we believe is acceptable. In the future, should the SDT decide to use 59.7 Hz as the basis for the FRO, than it will need to follow a methodology similar to the other interconnections for determining the credible multiple contingency to cover.
Yes
Yes

EEI supports the efforts and improvements made by the Standards Drafting Team (SDT) in the latest version of BAL-003 and believe those changes have been responsive to the directives in Order 693. However, we recognizes that the Industry has struggled with this standard and remains split as to how best to respond to those directives and in some cases there are those who question whether a standard is even necessary. Given the many open issues and the concerns expressed by stakeholders we anticipate that this standard will once again fail to achieve sufficient support to gain approval. Should the Standard fail to achieve ballet approval, it is our hope that NERC Staff and the NERC Board of Trustees will allow the SDT a little more time to resolve any final issues that have been identified in this latest ballet. Although we recognize that May 31, 2013 does not leave the ERO with a lot of time to comply with this FERC imposed deadline, we still remain confident that given the progress made by the SDT a standard, which is acceptable to the Industry, is still possible. To the extent EEI can help, we are committed to working with member companies to communicate the issues and exchange insights from the SDT to help as we can to achieve a positive outcome.

As provided in question 2 below, AEP does not agree with the definition containing the Frequency Response Sharing Group as this function does not exist at this point in time.
No
AEP does not necessarily disagree with the words of the definition. However, AEP does not believe it is appropriate to define a new function that is not in the NERC Rules of Procedure, NERC Statement of Registry Criteria, or the NERC Functional Model. It is premature to incorporate this entity without a proposed change to these governing NERC documents.
No
AEP believes this question in the comment form is incorrect. It appears that R3 and R4 are inadvertenly merged together.
No
AEP is under the impression that there are some requirements, which though not explicitly stated, are implied in Attachment A. AEP feels strongly that these “sub-requirements” should be clarified and contained within the body of the requirements of the standard.
There is no leverage for the BA to require the generator to carry their burden of addressing governor settings or droop settings, yet the BA is obligated to meet some performance measures in that regard. This revision adds new performance measure responsibilities on the BA who likely has no direct control over every resource affecting their performance within their footprint. We are not necessarily challenging the performance measures themselves, nor their underlying objectives, however AEP views this as a gap in responsibilities which potentially effects reliability. AEP suggests that GOPs be considered as part of this standard so that their performance can be factored into the process to meet the performance objectives.

We commend the drafting team for a rigorous approach to this new and important standard. Being observers who have a strong interest in this standard as it applies to much of the research that we do, but not stakeholders of the ultimate standard, we submit our overall comments as recommendations here. We believe there are a few potential issues, that may at least need more thought before going forward. The first is the credit for LR. (1) Overfrequency can be an issue: using ERCOT as an example, with -282 MW/0.1Hz response and 1400 MW of LR all responsive at 59.7 Hz, if just meeting FRO requirements, the 1400MW LR can all be triggered with a loss of (282*3=) 846MW, causing (1400-846=)554MW of overgeneration. This can be exacerbated by further increases of LR without recognition of the triggering frequency, and the disconnect between BA and interconnection in the other interconnections. (2) With crediting LR toward the Interconnection, it will not give incentive toward BAs to provide it. We believe the LR should contribute to the BA FRO rather than discount the IFRO. (3) There is no requirement for frequency response capacity (ie MW) available to provide the FR. This is a nonissue in today's world with the amount of spinning reserve already available, but the issue could be apparent on future systems with increased reserve sharing, or reserve capacity from resources that operate in modes which do not provide frequency response. The European Interconnection requirement has two intentions: a 3,000 MW capacity requirement and a 1,500 MW/0.1Hz FRO requirement that is allocated out to its Transmission System Operators. This could solve the issue with LR and generators, where LR is in MW and generation governing is in MW/0.1Hz. (4) It is likely, and from our understanding is true in some areas like ERCOT, that the LR is selected based on market solutions, and may not be available all times of the year. This is another reason why the LR should contribute to the BA FRO rather than discount the IFRO. (5) It may be beneficial to guide frequency settings for LR or even multiple settings to mimic a droop curve for LR. Other potential issues not related to the LR. We think the SDT has done an outstanding job on reviewing the data sets and determining statistically based values to better account for different factors that may affect minimum frequency levels. We agree that there are current issues in the primary governing response, but that there may be a disconnect in fixing those issues with the static values. We also agree that there is not an easy solution. In specific: (6) The static CB ratio might not incentivize BAs to improve response with increased inertia or faster responding governing response. (7) The static withdrawal BC'adj may not incentivize BAs to improve their governing response and limit their withdrawal. Improved technology may allow for better measurement to account for these issues dynamically rather than using static numbers. Guidance on increasing inertia, increasing governing speed, and reducing withdrawal should be considered by stakeholders. We thank NERC and the SDT for the opportunity to provide comments on this important standard.

The United Illuminating Company

UI believes the VRF should be High. The VRF justification for Medium is that the prior year's bias setting would exist in the control system so the impact would not cause a Cascade. UI thinks that is an adjustment factor that is applied after non-compliance is determined. Not having settings is likely to cause cascade so the VRF is High.

The supporting document on the standards page does not provide information on CB Ratio and why it is used. It significantly increases FRO and should be justified based upon strong technical basis and actual experience. (Please also see AZPS response to question 6, The Frequency Response Initiative Report should be on the Standards page).
NO: 1. The Frequency Response initiative report should be added to the standard as an appendix. It is not clear where to find this report. 2. The jusitification for dividing delta frequency with C to B ratio is not adequate and not clear.
NO: 1. Either do not use C to B Ratio or provide adequate rational for using it. It appears to make FRO unnecessarily too conservative and is not justified based upon experience. 2. The VRF is too complicated and hard to understand. It must be either simplified or should be followed by example. 3. The Frequency Response Obligation Methodology on Page 7 of "Procedure" does not show any formula (it is blank).
As mentioned in Item 8 above, the VRF language is too complicated and hard to follow. Even though the VRF poll is non binding, it needs to be clear and simple enough to be understood.

(1) Page 2, Balancing Authority Frequency Response Obligation (FRO) and Frequency Bias Setting: States that the ERO is responsible for “annually assigning an FRO and Frequency Bias Setting to each BA.” No mention is made of FRSGs. (2) Neither R1 nor the referenced Attachment A clarifies the FRM requirements for an FRSG to comply versus a BA. In particular, compared to BAL-002-0 R1.1, which clearly states that the BA may elect to fulfill its obligation through an FRSG and that in such cases the FRSG has the same responsibilities as each BA (that is a participant in the FRSG). (3)Attachment A refers to an FRSG calculating FRM, but the standard does not.

Purpose: Is the reference to ‘Interconnection Frequency’ supposed to be ‘Frequency Response’? This would be consistent with later wording in the standard. R1: (1) The acronym ‘FRO’ is used inconsistently within the document. (2) The phrase “to ensure that sufficient Frequency Response …” should be separated from the requirement as it is (i) not descriptive of the required actions; (ii) redundant with the stated purpose at the beginning of the standard. In general, such a drafting technique should be avoided as it may allow Responsible Entities to argue that a violation has not occurred where the specific action that is described has not been taken, but the purpose referenced in the requirement has been met. M1: The reference to ‘documented formula’ is not clear. Does this imply that the FRSG or BA have a record of their calculation? In addition, there is a typo, a random ‘)’ after FRM. M2: Should include the words ‘and uses a fixed Frequency Bias Setting…’ after overlap Regulation Service to make the wording consistent within the Requirement. M3: The wording of this measure switches tenses between ‘is’ and ‘was’. For consistency, we suggest that this be corrected. NERC Glossary definition of an FRSG is a group of BAs that collectively maintain, allocate and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members. No mention is made of the agreement including the sharing or delegation of responsibility related to FRM. Accordingly, the standard should only reference a BA being able to delegate responsibility to an FRSG if the RSG Agreement allows for such delegation. Data Retention 1.3.: (1) As the standard is currently drafted, both the BA and the FRSG would be required to retain data or evidence to show compliance with requirements R1 and M1. It is unclear whether this is the intention, or whether it would be acceptable that just one or the other would maintain such records. (2) In the third paragraph, it should be clarified who is required to keep information related to non compliance if the BA belongs to an FRSG – the BA or the FRSG or both.

BPA is responding to 3.1 and 3.2 of R3. The bullets listed in question 3 on the original comment form appear to be for Requirement R4. BPA is in support of R3.1 and R3.2.
No
BPA does not agree with the methodology in Attachment A. Please see BPA's response to question 6 as well as BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf.
No
BPA does not agree with the methodologies outlined in Attachment B. Please see BPA's response to question 6 as well as BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf
No
BPA does not have specific changes to the methodology to suggest, however, a methodology that arrives at a negative 840 MW per tenth Hz for WECC is obviously under-calculating the frequency bias obligation. Currently WECC has an interconnection bias of over 2000 MW / 0.1Hz and with this bias the frequency is steady state following point B on the frequency response curve. BPA would expect to see frequency decline after point B if the FBO is lowered by almost 60%. BPA also must reiterate that there is still a problem with the method used for modifying the FBO and frequency bias for Balancing Authorities. A high-performing Balancing Authority will have its frequency bias increased each year due to higher response during the events chosen by the ERO. Conversely, a low-performing Balancing Authority will have its frequency bias reduced each year due to lower response during the events

chosen by the ERO.
No
BPA continues to fundamentally disagree with the approach that BAL-003-1 is developing into. Please reference BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf.

Attachment A states that Form 1 is posted annually. The ERO support document selects events annually. The timing for the two documents needs to be aligned so that the set of selected events does not change from quarter to quarter. (If three events are selected for the first quarter those same events will be a sub-set of the 20 events selected for the annual compliance calculations.)
No
The industry needs some assurance that the calculation of the Interconnection FRO described in the report cannot be changed outside of the Standards Process for approval by the industry. We do not support using a 4500 MW loss as the basis for determining the FRO for the Eastern Interconnection for future events. However, as the calculation also includes 59.5 Hz as the basis for determining the FRO, the result is an allocation which can be supported. To the extent that the standard drafting team moves in the direction of using 59.7 Hz as the basis for the FRO, then it needs to follow a methodology similar to the other Interconnections for determining the credible multiple contingency to cover.
Yes
Yes
Please refer to comments for question 9.
The organization selecting events must ensure that the change in frequency is outside the normal dead-band of generator governors. Many of the events selected in the past have not been outside the dead-band and therefore, the frequency response was much less than expected. Southern Company proposes .07 which is consistant with WECC.

PSEG entities will vote “Negative” on the standard until this Project 2007-12 achieves the following: 1. It coordinates with Project 2010-14.1 Phase 1 of Balancing Authority Reliability-based Controls Reserves, specifically BAL-012-1, regarding (a) definitions and (b) requirements that address frequency response in both standards. a. Definitions that need to be coordinated: BAL-003-2 – “Frequency Response Obligation” and BAL-012-1 – “Frequency Responsive Reserve.” b. Requirements that need to be coordinated: i. BAL-003-1, per R1, states “Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation.” ii. BAL-012 requires BAs to have sufficient Frequency Responsive Reserves per R6, which requires BAs to “assess, on at least an hourly basis, that it has sufficient Regulating Reserve, Contingency Reserve, and Frequency Responsive Reserve to meet its reserve plan(s) to ensure reliable operation of the Bulk Electric System.” For Frequency Responsive Reserves, R3 in BAL-012-1 requires BAs to develop an annual plan for these reserves. BAs should not be subject to duplicative requirements for frequency response requirements in different standards that are underdevelopment. Only one standard needs to define the frequency response requirements for BAs (we suggest that be BAL-003-1), although other standards, such as BAL-012-1, may reference that obligation. However, this decision should be made by consensus between the two SDTs. 2. It coordinates with Project 2010-14.1 Phase 1 of Balancing Authority Reliability-based Controls Reserves, specifically BAL-012-1, to develop an application guide that would be attached to one of the standards and that could be referenced by each standard. The application guide would include: a. A hypothetical implementation plan for a BA that demonstrates how the BA may meet its Frequency Response Obligation or Frequency Responsive Reserve prior to an event. This is a technical issue and should not be confused with the institutional issue in #3 below. b. An explanation of the relationship between Regulating Reserve, Contingency Reserve, and Frequency Responsive Reserve contained in

BAL-012-1 so that potential double counting (and whether that is proper of improper), is addressed. 3. Project 2007-12's "Frequency Response Standard Background Document" dated October, 2012 lists several methods of obtaining Frequency Response. Most of those are extracted below. We have provided questions and commentary that we ask the team to address. a. "Regulation services." This is addressed in BAL-001-0.1a. The purpose of this standard is "To maintain Interconnection STEADY-STATE FREQUENCY within defined limits by balancing real power demand and supply in real-time. How is this related to Frequency Response for a disturbance? (The team may answer this as part of 2.b above.) b. "Through a tariff (e.g. Frequency Response and regulation service). " The team is advised to review the actual pro-forma OATT schedule for Schedule 3 "Regulation and Frequency Response Service" which is specifically limited to services providers that are "capable of providing this service as necessary to follow the moment-by-moment changes in load." Again, how is this related to Frequency Response for a disturbance? (The team may answer this as part of 2.b above.) c. "From generators through an interconnection agreement." The FERC's pro-forma Standard Large Generator Interconnection Agreement (LGIA) per Order 2003 contains no requirement for generators to provide Frequency Response service, and we are not aware on ANY interconnection agreement that does. We ask that the team point to ANY interconnection agreement with such a requirement. Modification of an interconnection agreement to incorporate such a requirement would require the consent of both parties. d. "Contract with an internal resource or loads." Since Frequency Response service would likely be considered as a necessary service to provide Transmission Service under an OATT, it would require a tariff. What existing tariff applies in the U.S.? The "methods" above that the team has listed have the factual errors described. The standard BAL-003-1 cannot be implemented until the necessary tariffs are developed that permit BAs and FRSGs to contract for Frequency Response services. Once that is done, BAL-003-1 can dictate the performance requirements of a BA or FRSG. • For context, FERC OATT schedules relevant to Frequency Response DO NOT set performance requirements. Schedule 3 (Regulation and Frequency Response Service) sets forth a tariff for the service, while BAL-001-0.1a sets forth performance requirements in aggregate for a BA or RSG. Likewise, Schedule 5 (Operating Reserve - Spinning Reserve Service) and Schedule 6 (Operating Reserve - Supplemental Reserve Service) set tariffs for both services, while BAL-002-1 sets performance requirement. Without an OATT schedule for Frequency Response service, BAs and FRSGs will have no means to contract with generators or loads to provide Frequency Response per BAL-003-1. The team should address this concern.

As indicated in our previous comments, the status of Attachment A is unclear. It is a mixture of requirements, criteria, process and guideline. Making a direct reference in the standard's requirements (R1 and R2) makes Attachment A as part of the requirement and hence is enforceable, but it contains process and guideline information that is not subject to assessment. On the other hand, the absence of a Measure to assess adherence to the criteria and process suggests that Attachment A is not enforceable. It is this ambiguity that makes it difficult for the industry to assess the extent to which they must follow the process. Again, we urge the SDT to keep only the criteria/process parts that must be adhered to in Attachment A, and extract the remaining parts and place them in a guideline document, or an appendix. In addition, the Responsible Entities are required to submit Form 1 and Form 2, but such requirements are not written explicitly as "shall", and are imbedded in the Attachement whose mandatory status is unclear. This makes the standard very confusing from an Responsible Entity's obligation and compliance perspective.
Yes

Yes
No
a. We do not support R2 as drafted, specifically the phrase “until directed to change by the ERO”. We do not agree that the ERO has any authority to “direct” a BA or FRSG, or any responsible entities, to make changes to the Frequency Bias Setting or take any operating or operations planning actions. We suggest to replace the word “directed” with “requested”. b. In R2, the words “subject to” can be interpreted differently. We suggest to replace them with “in accordance with” to parallel the intent as conveyed in R1. c. We are still concerned with the status of Attachment A, as indicated in our comments submitted under Q4 – that it is unclear if the materials in Attachment A must be adhered to or not. A standard should not have an attachment whose enforcement status is unclear as part of a requirement. d. FRS Forms 1 and 2 are referenced in Attachment 1, which itself has an unclear status on measurability and enforceability. It is also unclear if FRS Forms 1 and 2 must be used to submit the requested data. Collectively, Attachment 1, FRS Form 1 and Form 2 make the standard very confusing as to which parts must be complied with. Much better clarity is needed to clearly convey the standard ‘s requirements that are measurable, enforceable and must be complied with.
The proposed effective date for this standard conflicts with Ontario regulatory practice respecting the effective date of implementing approved standards. It is suggested that this conflict be removed by appending to each of Section A1.3 and A1.4, after “months after applicable regulatory approval”, of the standard to the following effect: “, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.” The same change should be made to the two bullets in the proposed Implementation Plan.

NextEra Energy
Yes
NextEra Energy does not support the changes made. It is concerned that certian changes were made to help some large East coast entities that could not comply at the expense of the FRCC region. Specifically, now on page 3 of Attachment A 4th paragraph from the bottom the statement is made “ sets its frequency bias to the greater of”. We believe that this must be changed to either Statement 1 “ Any number the BA chooses between 100% etc” Or Statement 2 “ Interconnection minimum as determined by the ERO” Without this change, NextEra beleives the FRCC will be unfiarly treated relative to others on the Eastern Interconnection. The technical reasons for this is concern was explained during the Standard Drafting Team meetings. In addition, the ERO limit which is set at 0.9% of load should be changed to read within 0.8 or 0.9% of peak load based on the BA’s choice. Also, see page 7 of the Procedure document and compare to page 1 of Attachment A. The formulae abbreviations for the variables in the Procedure are not likewise abbreviated in Attachment A. For example, “Credit for LR” on Attachment A is “CLR” in the Procedure, but it requires cross checking each document to figure this out. Or CBr in Attachment A, Table 1 is represented as DFCBR in the Procedure, Page 7. Since the same variables are being described, these should be represented the same way in both documents throughout. 2. Similarly, is “IFRO” in Table 1 of Attachment A the same as “FROInt” of the equation that follows on page 2? The same abbreviation should be used to represent this variable. The documents should be revised in general along these lines for all terms. 3. In Procedure document, page 5, paragraph 3 it should read “Table 2”, not “1”. 4. In the Procedure, it would be good to show Table 1 and Table 2 as Table 1 of Attachment A (i.e. use table lines and borders). 5. At least in the first usage, ERO in the Procedure document should be spelled out as “Electric Reliability Organization (ERO)”. 6. In Table 1 of Attachment A, the two footnotes preceded by asterisks (single and double on page 2) should be connected to the table by adding a single superscripted asterisk to the Eastern UFLS value of 59.5, and a double superscripted asterisk to the ERCOT LR value of 1,400.

Individual
Don Jones
Texas Reliability Entity
Yes
Yes
Yes
It appears that R3.2 is based on the assumption that governor dead-band settings are 0.036 Hz for all interconnections with multiple BAs. While the ERCOT region has a standard 0.036 Hz dead-band specified in the ERCOT Protocols and Operating Guides, we are not sure if this is applicable to the other regions.
Yes
1. The calculation for the FRO for ERCOT includes a credit of 1400 MW for load resources. 1400 MW is currently the maximum amount of LR that can be procured through the ERCOT ancillary service process. There can be periods during the day where 1400 MW was not procured or is not available (It was noted during the summer of 2012 that on some days, only 900 MW of LR was available through the ancillary service process). Should the calculated IFRO (-286 MW per 0.1 Hz) be modified to account for this variation? 2. Background Document says: “Attachment A proposes the following Interconnection event criteria as a basis to determine an Interconnection’s Frequency Response Obligation: • Largest category C loss-of-resource (N-2) event • Largest total generating plant with common voltage switchyard • Largest loss of generation in the interconnection in the last 10 years” For ERCOT, the largest loss of generation in the last 10 years was over 3400 MW, and does not match the 2750 MW (N-2) value used for the IFRO calculation.
Yes
1. Event Selection Criteria Item 2: Should certain events require mandatory inclusion for FRM calculation (i.e. DCS events)? 2. Event Selection Criteria Item 6: We disagree with the way this is worded. If a unit trips during this time, as it often can, measured frequency response needs to occur. We understand that the results are impacted by the grid condition and perhaps that is why the SDT decided to exclude the issue. Need to define what is intended by a “large” interchange ramp schedule or load change. May also want to consider changing the language from “will be excluded from consideration” to “MAY be excluded from consideration”.

No
The PPL Affiliates support the comments of the SERC OC Standards Review Group on this question.
Yes
PPL Affiliates suggest additional detail be added to the definition to ensure the members of the FRSG are all within the same interconnection. The following definition includes the suggested changes: A group whose members consist of two or more Balancing Authorities all within a single interconnection that collectively operate resources required to jointly meet the sum of the Frequency Response Obligations of its members.
No
The NERC posting did not include a redline to Attachment A, therefore, it is not clear what modifications were made. However, there are several modifications that would add clarity to the attachment. The PPL Affiliates support the comments of the SERC OC Standards Review Group on this question, additionally, the following issues should be addressed: In Attachment A, page 3 and elsewhere, clarify that temporary or small transfers of load or generation between BAs do not require notification to the ERO or changes to the FBS or CPS limits. In Attachment A, page 4, a BA should be allowed to be exempt from evaluation any single frequency event where non-conforming load performs contrary to the performance of conventional load (ie. during a frequency decline, the non-conforming load simultaneously increases significantly). By nature, non-conforming load is totally unpredictable, changes quickly, and fluctuates widely. Other than interruption, the BA has no control over the actions of such loads nor can the BA predict or assume any “normal” action by a non-conforming load during a frequency disturbance event. Setting a limit on the number of events that a BA could exempt (regardless of the reason) from FR evaluation in any given year would be more fair and effective in evaluating a BA’s frequency response performance.
No
The PPL Affiliates support the comments of the SERC OC Standards Review Group on this question
Yes
The PPL Affiliates applaud the SDT for developing this technical justification document.
No
The PPL Affiliates are concerned that the document referred to “Attachment A” is directly referenced in the proposed standard’s requirements but not actually attached to the standard itself as Attachment A. Therefore, it is not clear how the proposed document could be modified in the future. Having such material incorporated into a standard takes away from the open and transparent stakeholder drive process.

With what periodicity does a BA’s frequency bias setting have to change to be considered variable bias? For example, if a BA changes it’s frequency bias setting monthly based on a percentage of each

month's forecast or historic load, is this considered variable bias subject to compliance with R3 in lieu of R4?
No
The target contingency protection criterion for the Eastern Interconnection is the largest event in the last 10 years (believed to be a 2007 event) which is inconsistent with the other Interconnections. Is periodic review required for this criteria? Will this criteria be revised after the referenced event is older than 10 years? Are the other three interconnection's target contingency protection criteria subject to revision if they experience an event larger than a category C? This BA believes that future periodic analysis should be defined and subsequent findings used to support changes via the standard revision process. What are the procedural requirements for revising Attachment A? This BA is concerned that the procedure for revising Attachment A is undefined and that, for example, the IFRO could be increased absent the formal standard revision process, increasing a BA's FRO and subsequently increasing a BA's compliance risk without providing BA's the opportunity to review, comment, and ballot. Related to the previous comment/question, how often are the statistically derived values in Table 1 subject to a required update? For example, the Eastern Interconnection is adjusted due to observed primary frequency response withdrawal ('lazy L' characteristic). The other Interconnections are adjusted for observed differences between point C and point B. As the frequency response characteristics of any Interconnection change, is Table 1 subject to required analysis and revision? This BA believes that future periodic analysis should be defined and subsequent findings used to support changes via the standard revision process. Attachment A indicates that a BA may exclude an event from annual Form 1 FRM evaluation only if its tie-line or frequency data is corrupt or unavailable. This exempts numerous scenarios that could result in a poor response score due to system variations. These could include, but are not limited to, changing energy schedules, changes in load, and AGC driving units up or down due to the ACE value at the time of the frequency event. This subjects the BA to undue compliance risk even though the BA may have adequate frequency responsive resources at the time. This BA suggests that the FRSDT adopt language (and Form 2 functionality) that allows the exclusion of events that are skewed by these types of situations. Attachment A and Forms 1 & 2 specify that 20 to 52 seconds will be used as the post-event B point average for FRM determination. The number of fast responding resources will increase as the technology for batteries, flywheels, and frequency controlled demand side devices moves forward over time. The 20 to 52 second interval does not adequately incentivize the devopment of these technologies.
No
The Procedure indicates that events that occur when 'large interchange schedule ramping or load change is happening' and 'events occurring within 5 minutes of the top of the hour' should be excluded from consideration. Since interchange schedule ramping and load change occurs at the BA level, this BA believes that the Procedure allows for the selection of events that occur when a BA is experiencing these conditions but Attachment A does not allow for exemption of these events. Also, the Procedure specifies that events that occur at the top of the hour be excluded, if other qualifying events exist, but this does not take into consideration energy markets that allow for sub-hourly schedule changes (e.g. 15 minutes) and the BA is not permitted to exempt these events on Form 1 subjecting the BA to undue compliance risks.
Yes
Yes
No
See previous comments. Also, this standard should be applicable to GOP's as well as BA's with, at a minimum, the following requirements added: Each GOP shall follow all directives of it's Balancing Authority pertaining to frequency responsive operation, including but not limited to the status, droop & deadband settings of their governors. Each GOP shall provide to their BA the status and droop & deadband settings of their governors, and headroom available to respond to frequency deviations, as requested.

Duke Energy
Greg Rowland
Duke Energy
No
The definition reads as if the FRM is the median of all of the observations reported by the Balancing Authorities and Frequency Response Sharing Groups. Duke Energy would suggest that the definition read, “The median of all of the Frequency Response observations reported annually by a Frequency Response Sharing Group, or Balancing Authority if not a participant in a Frequency Response Sharing Group, for frequency events specified by the ERO. The Frequency Response Measure is calculated as MW/0.1Hz.”
No
As a Balancing Authority may not be the entity maintaining or supplying resources, but would be responsible for utilizing applicable resources within its BA Area, Duke Energy would suggest the following definition, “A group whose members consist of two or more Balancing Authorities that collectively utilize operating resources required to achieve a group FRM equal to or more negative than the sum of the Frequency Response Obligations of its members.”
No
Duke Energy agrees with allowing single-BA Interconnections to utilize a variable Frequency Bias Setting (FBS). Duke Energy disagrees with NERC allowing Balancing Authorities in a multiple-BA Interconnection to change the ACE and bounds by which the Balancing Authorities are measured under BAL-001 and BAL-002 by operating to a variable FBS. It is desired that a Balancing Authority be capable of recognizing the amount of primary response available in real-time operation, such information can be included among other information in the generation control algorithm; however, the obligation to support the Interconnection frequency under the secondary control standards, and the amount provided for any given frequency, should be based on the same criteria across all Balancing Authorities of the same size. Nathan Cohn in his comments on Union Electric’s use of a variable FBS expressed similar concern regarding the equitable sharing of the obligation to support Interconnection frequency in a multiple-BA Interconnection. Take for example two Balancing Authorities with equal total generation and load, but one operating under a fixed FBS and the other operating under a variable FBS. To the extent that a Balancing Authority is not providing Frequency Response comparable to its fixed Frequency Bias Setting, its ACE will reflect the difference to be covered with secondary control and the Balancing Authority will be measured in a manner similar to other BAs of its “size” based upon the FBS. To the extent that the other BA using a variable FBS is not providing Frequency Response comparable to what it would be allocated using a fixed FBS, its ACE will not reflect the difference or any further obligation to support Interconnection frequency at that time with secondary control. Duke Energy’s concern regarding non-comparable treatment of all BAs is further amplified by the lack of scrutiny placed on the BA algorithm used to determine the real-time variable FBS, to ensure that compliance cannot be gamed by such use.
No
As indicated in our comments in the past, Duke Energy is certain that as the Interconnection Frequency Bias Setting (FBS) is set closer to the actual Frequency Response in a multi-BA Interconnection, most BAs will be challenged in meeting CPS2, while CPS1 and the proposed Balancing Authority ACE Limit (BAAL) will be more achieveable bounds, and in some cases CPS1 performance will improve. Though probably most of the BAs may welcome a FBS set as high in magnitude as allowed to address the potential compliance risk, there are some which may desire to set their FBS closer to their required minimum allocation rather than have to take on a larger obligation in frequency support under the secondary control measures. Duke Energy believes that this proposed standard should incent BAs to provide more than their share of Frequency Response to the Interconnection and allow that good performance to be recognized; however the requirements described in Attachment A for determining the minimum Frequency Bias Setting (FBS), which requires that the FBS be set no lower in magnitude than the FRM, will leave certain over-performing BAs with no choice but to reduce their actual Frequency Response (still well-above their FRO) if they want to operate with a FBS set closer to the Interconnection Minimum allocation and be relieved of the associated increased obligation for frequency support under the secondary control measures. The FBS is embedded within the secondary control measures of CPS1, CPS2 and the draft Balancing Authority

ACE Limit (BAAL). Comparable treatment of similarly-sized BAs (based upon the FRO allocation) is only possible if all BAs are provided the same minimum FBS requirement. To the extent that a BA provides more than its share of response to events, it's over-performance will only be recognized if its ACE is allowed to reflect a FBS comparable to its peers, allowing its over-performance to be reflected in ACE in support of bringing frequency closer to 60 Hz. Generation control algorithms implemented today to optimize CPS1 will allow non-zero ACE when in support Interconnection frequency within bounds determined by the BA – there should be no concern of "response withdrawal" with such algorithms in place, the BA will simply get credit for such performance. As depicted in the current document, the over-performing BA would be required to set its minimum FBS at its FRM (or greater in magnitude), taking away what should be considered over-performance, erasing it in ACE, and turning it into an obligation under the secondary control measures. Based upon the draft, the only way that the BA could be treated comparably to other similarly sized BAs held only to operating to the Interconnection Minimum allocation, would be to reduce its actual response in FRM to a value less in magnitude than its Interconnection Minimum allocation. Duke Energy believes that BAs should be incented to provide more than their share of Frequency Response, and be given the opportunity to report performance on a basis comparable to similar-sized BAs. Our opinion is that Attachment A ensures that the Interconnection Frequency Bias Setting will remain at some margin above the actual Interconnection Frequency Response in magnitude – the reliability of the Interconnection will not be at risk by allowing over-performing BAs to operate and report performance on a comparable basis to other similarly-sized BAs based upon the Interconnection Minimum allocation if they choose to do so – to that extent, Duke Energy suggests that the language on page 3 be changed to: "A BA using a fixed Frequency Bias Setting may set its Frequency Bias Setting to any number the BA chooses up to 125% of its Frequency Response Measure as calculated on FRS Form 1, but no less in magnitude than its Interconnection Minimum allocation as determined by the ERO." Regarding the argument which could be offered that a larger FBS in magnitude will also allow wider bounds for control performance, Duke Energy agrees that a large portion of the BA operation will be around 60 Hz where such a benefit could be realized, however it would also come at the cost of a larger obligation than other comparably-sized BAs in sustained support of frequency during the more critical times of significant deviation from 60 Hz where the BA's compliance could be at risk. Below 59.95 Hz in the Eastern Interconnection (the Frequency Trigger Limit under BAAL), the additional MWs needed to be compliant for any given frequency are greater than the MWs of imbalance allowed by the larger BAAL bound – comparably-sized BAs will not be comparably judged if the standard forces over-performing BAs to assume a larger FBS (in magnitude) than their peers – that should be the decision of the BA. We believe that the proposed language above will create the proper incentive for a Balancing Authority to provide more than its minimum allocation of Frequency Response, and allow it to choose if it wants to make that performance part of a larger FBS (in magnitude), knowing the associated risks and benefits of that decision. Duke Energy supports this standard allowing for Frequency Response Sharing Groups, however the requirements and supporting documents need to clearly allow the FRSG to be treated no differently than if it was a Balancing Authority and shield the participating BAs from compliance scrutiny when all scrutiny should be placed on the FRSG performance as a whole. At the top of Page 3, the standard attachment allows the FRSG to "calculate a group NIA and measure the group response to all events in the reporting year on a single FRS Form 1", however at the bottom of page 3, the standard attachment still requires the FRSG BAs to individually fill out Form 1 and Form 2 for the purposes of determining the minimum Frequency Bias Setting. Duke Energy believes that the standard language in Attachment A, and the supporting form(s), should allow the FRSG, if it chooses, to also report the split of the group FRM which the BAs will use to individually determine their Frequency Bias Setting, rather than require each BA in an FRSG to still maintain Form 1 and Form 2 data. Form 1 could be modified for the FRSG to report the group's FRM along with the split of the FRM among the members, and another form could be developed for each FRSG BA to fill out, replicating only the section of Form 1 (column S) where each BA could provide values for its FRM allocation, its desired FBS, its minimum FBS allocation, and so on.

No

Duke Energy agrees with allowing the ERO to perform this function, however the industry needs some assurance that this Procedure cannot be changed outside of the Standards Process for approval by the industry. In the sixth line of the third paragraph on page 5, the statement should reference Table 2. Page 5 reads as if the BAs will submit their data based upon Form 1 which includes an adjustment to the Interconnection peak load (initially 0.9), and then the ERO will determine whether the Interconnection minimum FBS is still more than 20% above the measured response – if so, the

minimum FBS will be adjusted, requiring the BAs to reassess their new minimum FBS based upon a different factor, and decide whether to use that value or choose a value up to 125% of their FRM, resulting in another iteration of values being submitted to the ERO. If the ERO is going to do an independent assessment of Interconnection Frequency Response to the events, on an annual basis prior to gathering data from the BAs, the ERO could compare the total FBS being used by the BAs against the estimated Frequency Response over that period to determine if an adjustment is warranted, and then the ERO could include the appropriate adjustment factor (0.9, 0.8, etc..) in Form 1 for the BAs to use. If the ERO is not going to estimate the Frequency Response aside from the BAs, multiple iterations will be likely. Duke Energy suggests the following language to cover the point above: "On an annual basis, the ERO will review the Interconnection total minimum Frequency Bias Setting for the prior period and compare it against the Interconnection's total natural Frequency Response determined for that period. If an Interconnection's total minimum Frequency Bias Setting exceeds (in absolute value) the Interconnection's total natural Frequency Response by more (in absolute value) than 0.2 percentage points of the Interconnection non-coincident peak load (expressed in MW/0.1Hz), the minimum Frequency Bias Setting for BAs within that Interconnection may be reduced (in absolute value) based on the technical evaluation and consultation with the regions affected by 0.1 percentage point of Interconnection non-coincident peak load (expressed in MW/0.1Hz) to better match that Frequency Bias Setting and natural Frequency Response. The ERO will include the adjustment factor in the Interconnection Form 1 used by the Balancing Authorities for the calculation of the new minimum Frequency Bias Setting. The Form 1 information from the Balancing Authorities will be gathered by the ERO in coordination with the regions of each Interconnection to determine the final Interconnection Frequency Bias Setting for the next period."
No
Similar to our earlier concern, the industry needs some assurance that the calculation of the Interconnection FRO described in the report cannot be changed outside of the Standards Process for approval by the industry. Duke Energy does not support using a 4500 MW loss as the basis for determining the FRO for the Eastern Interconnection for future events. However, as the calculation also includes 59.5 Hz as the basis for determining the FRO, the result is an allocation which can be supported. To the extent that the standard drafting team moves in the direction of using 59.7 Hz as the basis for the FRO, then it needs to follow a methodology similar to the other Interconnections for determining the credible multiple contingency to cover.
Yes
Though Duke Energy does not agree with some of the points in the Background Document, it does justify the rationale used by the SDT. Additional comments: at the top of page 23, it states that the basic Frequency Response Obligation is based on non-coincident peak load and generation data reported in FERC Form 714, however the actual calculation is missing and should be based upon the reported MWh, not the peak load as stated. At the bottom of page 23, it states that Attachment A proposes the three options for event criteria, however doesn't clarify why it was chosen that the Eastern Interconnection would be held to the largest event over the last 10 years, while others will be based upon the largest category C loss-of-resource (N-2) event.
No
Given the FERC deadline approaching for NERC to deliver a Frequency Response standard, Duke Energy supports the adoption of this standard with some reservations. We believe that the proposed standard addresses the FERC directive to NERC, however it also introduces some longer-term issues related to secondary control and related costs that may have not been anticipated by the FERC. To that point, Duke Energy believes that if this standard is adopted, the industry will have the time and opportunity through the NERC standards development process to mitigate some of the concerns presented in our comments."
The concern raised in Duke Energy's comments in item 4 will not be a factor for a few years, but will be an issue as more and more BAs are in the position of their FRM being better than the Interconnection Minimum allocation. We believe that the language that we proposed for calculating the minimum FBS in a multiple-BA Interconnection allows for the proper incentives for BAs to maintain FRM much better than required, and allows for comparable measurement of secondary control performance between similarly-sized BAs, while presenting no risk to reliability.

We believe that refinements to the definition were needed.
No
We agree that a definition is needed and thank the drafting team for writing one. However, we believe additional refinement of the definition is necessary. Although the definition appears to be written to parallel the Reserve Sharing Group definition, we think the definition needs to be simplified. For one, it encompasses actions that are not necessary. For instance, the proposed definition includes the action to “maintain operating resources”. This could literally include generating plant maintenance. We do not agree that a Frequency Response Sharing Group would jointly perform maintenance on their plants. In fact, since the definition applies to BAs, it is entirely possible within the functional model that the BAs do not even own the plants and could not perform joint maintenance. We assume the purpose of including “maintain” was to recognize that maintenance of generating resources would need to be coordinated to ensure that there was sufficient frequency response reserve. We do not believe this needs to be explicitly identified in the definition. Furthermore, we find the use of “operating resource” as a source of potential confusion. While we understand operating resource is intended to mean a facility that provides the ability to increase or decrease MW output based on the frequency deviation, resource has various meanings throughout the standards and its use here could be confusing and contradictory. For instance, TOP-006-2 R1 discusses transmission resources. Furthermore, if an “operating resource” is capable of increasing or decreasing MW output based on frequency deviation, what is a “resource”? In other words, why is “operating” added to the term “resource”? We think it is best to avoid use of the term operating resource and, thus, recommend changing the definition to: “A group of two or more Balancing Authorities that share frequency response reserves and are required to jointly meet the Frequency Response Obligations of its members.”
Yes
No
(1) Frequency Response Obligation (FRO) is used inconsistently with the proposed definition in the document. The document uses the term “Interconnection Frequency Response Obligation” in many locations. However, FRO specifically is defined as the BA’s “share of the required Frequency Response”. It does not apply to the Interconnection. How can the Interconnection have a share of the required frequency response? A new term may need to be defined for the Interconnection required Frequency Response. (2) On page 3 Attachment A states the ERO will post the Frequency Bias Setting for each BA along with their Frequency Response Obligation. Later on the same page, the document states that the BA shall set its Frequency Bias Setting to 100% to 125% of it Frequency Response Measure or Interconnection Minimum. What is the purpose of the ERO determining Frequency Bias Settings if the settings are not going to be used by the BA? What are we missing in the explanation? (3) Late on page 3, the document states that BAs are encouraged to notify NERC if load or generation is transferred. Section 4(a) on page 8 of the Rules of Procedure Appendix 5A – Organization Registration and Certification Manual indicates that changes to a Registered Entity’s footprint actually triggers a potential certification audit. Since BAs are required to be certified and moving generation or load from the metered boundaries of one BA to another BA would represent a change in footprint, we suggest removing the word “encouraged” and stating affirmatively that BAs must notify NERC of such changes and referencing the appropriate section of the Rules of Procedure. Otherwise, BAs may not realize notification is actually required.
Yes

Overall, we agree. However, we suggest the document clarify that the ERO shall perform these tasks in coordination with the Resources Subcommittee. It consists of industry experts that can be an extra resource to NERC. Furthermore, NERC staff working with the Resources Subcommittee will provide additional transparency to the process.
Yes
We agree that this method will provide sufficient frequency response. However, we believe Interconnection Frequency Response Obligation is used inconsistentently with the definition of Frequency Response Obligation as documented in our response to other comments.
No
(1) The formula for calculating Frequency Response Obligation appears to be missing on page 23. (2) We are confused by the varying sample rates for the different scan rates in the Definitions of Frequency Values for Frequency Response Calculation table on page 13. It would appear that the time range of values for the average B value varies more than necessary by scan rate. For example, for 2-second scan rates, sampling would start at 20 seconds and end at 52 seconds. However, for the 4-second scan rates, sampling starts at 24 seconds and ends at 48 seconds. Why would it not also cover 20 and 52 seconds for a 4-second scan rate?
No
(1) We believe that the drafting team work has demonstrated that the standard is unnecessary. The data presented in the posting shows that all of the interconnections easily exceed the required Frequency Response necessary to avoid actuating UFLS relays. Since one of the main purposes of the standard is to provide sufficient Frequency Response, it would seem the purpose is already met without implementing and enforceable standard. So why is a standard needed to compel required Frequency Response if it is already provided? (2) Even though we believe the supporting data for the posting demonstrates the standard is unnecessary, we understand NERC is required by a FERC directive to provide a standard. Given this requirement, we do believe the drafting team has largely provided a reasonable standard and supporting documents that only require a few additional adjustments (see our comments in other questions for these adjustments) to finalize the standard. As a result, we will likely end up supporting the standard once these final adjustments are made.
(1) Please strike “that is a member of a multiple BA Interconnection” in R2 and R3. The language makes the requirements difficult to read. We understand this is trying to clarify that these requirements should not apply to BAs such as ERCOT since changing its Frequency Bias Setting does not need to be coordinated with other BAs among other issues, and we do not have an issue with this intent. However, there is an easier way to address this issue without creating a confusing requirement. The SDT should include seeking a variance for the ERCOT area in conjunction with developing the standard. (2) Please strike “in order to represent the Frequency Bias Setting for the combined Balancing Authority Area” in Requirement R4 as it is superfluous and incorrect. First, the two bullets provide the necessary information making the statement unnecessary. Second, the BA Areas are not combined into a single BA Area as implied with the statement “combined Balancing Authority Area”. They are still in fact two distinct BA Areas. (3) The data retention period for R1, R2, R3, and R4 is not consistent with the NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C – Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention section states that data shall be kept for the current calendar year plus the three previous calendar years. This could be up to four years which exceeds the BA audit period of three years. It is unnecessary for a BA to maintain evidence that was already verified in a prior audit. We recommend changing the evidence retention period to three years. (4) Has the drafting team coordinated the addition of the Frequency Response Sharing Group (FRSG) with the Functional Model Working Group and the NERC staff responsible for organizational registration? If not, please do so as NERC will need to be willing to register entities as a FRSG if it is to be utilized. Furthermore, the Functional Model Working Group should document the purpose and intent of the FRSG. (5) We disagree with the VSLs for R1. The VSLs are structured such that a BA’s or FRSG’s violation is dependent upon the rest of the interconnection to determine the severity level of the violation. If the BAs collectively fail to achieve the Interconnection Frequency Response obligation, a 2% violation of the Frequency Response Measure jumps from a Lower VSL to a High VSL. This should never be the case. No violation by a registered entity should become potentially more or less severe based on the violation of another entity. We encourage the drafting team to work with NERC Legal department in reviewing this VSL further as FERC has already allowed ISO/RTO violations investigation to draw in

third parties that potentially contributed to the ISO/RTO violation to ensure the appropriate party is fined. The principal is similar here in ensuring the appropriate BA is fined for its violation not the violations/failures of other BAs. The background document mentions on page 31 that the motivation for structuring the VSL in this manner was to prevent BAs in multiple BA interconnections from being sanctioned disproportionately. We appreciate the drafting team considering this issue but believe there is a simpler solution. Four VSLs could simply be written based on the percentage the BA misses its own Frequency Response Obligation. Furthermore, the compliance enforcement process already considers if the violation impacted reliability when assessing a sanction. (6) The Frequency Response Obligation (FRO) term is used inconsistently with the definition in the VSLs for R1. The first part of each BA implies that the Interconnection has an FRO. However, the definition specifically states that FRO is the BA's "share of the required Frequency Response". It does not apply to the Interconnection. How can the Interconnection have a share of the required frequency response? A new term may need to be defined for the Interconnection. (7) The implementation plan still references Requirement R5. There is no such requirement. (8) Requirement R1 is not consistent with the recent direction NERC has taken to refocus on reliability and looking forward during compliance audits rather than backwards. For instance, NERC has proposed monitoring internal controls of registered entities because this will provide a reasonable assurance that the registered entity is prepared to comply in the future. Current compliance audits focus mostly on past performance and provide no indication of future reliability. How does Requirement R1 support this forward looking vision when it is a lagging indicator that looks at historical performance? (9) Requirement R4 appears to be inconsistent with Requirement R1 and Attachment A. On page 3, Attachment A states the BA shall set its Frequency Bias Setting to 100% to 125% of it Frequency Response Measure or Interconnection Minimum. However, Requirement R4 states that the BA providing Overlap Regulation Service shall set its Frequency Bias Setting to the sum of its Frequency Bias Settings on FRS Form 1 and FRS Form 2 of its own BA and the BA to which its provides Overlap Regulation Service. For simplicity let's call the BA providing Overlap Regulation Service BA X and the BA receiving the service BA Y. Why would the BA X not set its Frequency Bias Setting to 100% to 125% of the sum of BA X's and BA Y's Frequency Response Measure? This would make Requirement R4 parallel with R2. (10) We do not understand the difference between the two bullets in Requirement R4. They appear to say essentially the same thing and the background document provides no discussion to distinguish their differences. Please provide further explanation.

No
The definition reads as if the FRM is the median of all of the observations reported by the Balancing Authorities and Frequency Response Sharing Groups. We agree with the Duke Energy suggestion that the definition read, "The median of all of the Frequency Response observations reported annually by a Frequency Response Sharing Group, or Balancing Authority if not a participant in a Frequency Response Sharing Group, for frequency events specified by the ERO. The Frequency Response Measure is calculated as MW/0.1Hz."
No
A Balancing Authority may not be the entity maintaining or supplying resources, but would be responsible for utilizing applicable resources within its BA Area. We would modify the Duke Energy suggestion to read as follows: "A group whose members consist of two or more Balancing Authorities that collectively utilize operating resources with a goal to achieve a group FRM equal to or more negative than the sum of the Frequency Response Obligations of its members."
No
It is important for NERC to monitor the interaction between the deployment of this standard and its impact on CPS1, CPS2, and BAAL. If performance in the CPS criteria is degraded, there should be a halt in the reduction of the minimum bias setting allowed. There is also concern that we are providing the correct incentives to the entities to provide the appropriate amount of frequency response. We also suggest that clarification be made so that changes in the BA's footprint that would necessitate

changes in the bias setting or the FRO be permanent changes, not just temporary. It is unclear how performance would be measured for a BA versus a frequency response sharing group.
No
We believe the industry needs some assurance that the calculation of the interconnection FRO cannot be changed without rigorous review and input from the industry. In addition the clarification should be made how the one in ten year loss for the Eastern Interconnection (4500 MW) would change after 10 years. Would the same methodology be used or would the largest Category C (n-2) be used?
Yes
We agree with the Duke Energy comments on this question.
The comments expressed herein represent a consensus of the views of the above named members of the SERC OC Standards Review Group only and should not be construed as the position of SERC Reliability Corporation, its board, or its officers.

The issue with proposed Reliability Standard BAL-003-1, requirement R1, is that the Annual Frequency Response Measure (FRM) is determined after the fact with an entity unable to identify or monitor compliance (on non-compliance) along the way. Also, the requirement seems to go the opposite direction of NERC's risk based initiatives where collecting historic compliance information become unsustainable.

If a BA is using a frequency bias setting and is not providing Overlap Regulation Service (supplying actual interchange, frequency response, and schedules to another BA), then we can assume it is supplying regulation service. Was the intent of the requirement to simply state that all BA's must have a bias setting less than zero at all times? Please clarify the intent of this requirement.
No
(1) This document lacks definitions of terms such as CCadj, DFcc, DFcbr, resource contingency criteria (in the attachment, this is called the "target contingency criteria"), etc. (2) Of value to entities would be a sample calculation. (3) "The largest category C (N-2) event is used for all interconnections except the Eastern which uses the largest event in the last 10 years". Why aren't all interconnections using the same design contingency design basis? (4) The NERC 2012 CPS2 bounds has an Eastern Interconnection frequency bias of -6,360 MW/.1Hz. Can the DT explain why this attachment refers to an Interconnection frequency response obligation of -1,002MW/.1Hz. This is a significant difference.

No
While the discussion of primary frequency response includes inertial energy, the term inertial energy is missing from the definition of “primary frequency response”.
No
The purpose of BAL-003 was to calculate frequency bias in the ACE equation used in BAL-001. The Standard is currently confusing to understand and it is unclear how the bias is calculated. It is recommended that efforts should be made to clarify the changes, especially Attachment A.
The VSL’s refer to the FRM (Frequency Response Measure). If that is the intent of the Standard, then GO’s and GOP’s should be included in the applicability since they are the entities responding to the AGC signals. If the intent is the FRO (Frequency Response Obligation) only, then the VSL’s should be updated.

Yes
Please see response to question 8. The FRM definition is acceptable within the context of the attachment description; however, without clarifying the terms under which the ERO specifies which events are to be measured, the FRM definition is too variable.
Yes
No
Please see response to question 8.

No
Exelon is troubled by the approach of having requirements that rely so heavily on the attachment to the standard. The use of both of the documents is required to be compliant and this makes it difficult to determine what the obligations are and increases the chance for error in interpretation. The suggested changes below in response to question 8 take information from the Attachment and establish requirements so that an entity does not have to go back and forth between the two documents to identify its obligations. Attachment A should then be modified to include examples of Forms 1 and 2 and instructions for completing the form for Balancing Authorities and Frequency Response Sharing Groups.
No
Please see response to question 8.
No
Exelon checked "no" because it does not support the current draft standard. Exelon's position is that efforts to modify frequency monitoring and control should be directed at the existing standards. Since Frequency Bias is already a component of ACE, and ACE performance is tracked by both CPS 1 and CPS 2, it seems evident that NERC already has in place mechanisms for evaluating frequency response. NERC already has in place mechanisms for ensuring sustained frequency response during a contingency, through the Disturbance Control Standard (DCS) and its requirement for the contingent Balancing Authority to deploy resources. Under the current BAL-003-0.1b language, Balancing Authorities are given a consistent means for determining frequency bias, via the minimum requirement of 1% peak generation or 1% peak load. Together with the above references to existing CPS 1 performance measurements, current standards meet the objectives outlined in BAL-003-1. This proposed draft BAL-003-1 complicates the setting of Frequency Bias and attempts to go beyond that purpose into frequency response performance, without clear rules for how to perform. Exelon is also concerned with moving this standard forward while there is an ongoing field trial that could impact whether this standard should be put into place. For example, waivers are in place for CPS 2 for participating Balancing Authorities and there is ongoing effort with the BAAL field trial set of standards that will establish performance metrics around frequency control. As an alternate approach to waiting to move forward on the standard, Exelon recommends the following BAL-003-1 Requirement language: R1. The ERO shall identify up to five [5] system frequency events in each Interconnection that will be included in the Form 1 and 2 data requests for Balancing Authorities by April 30th each year. R2. Each Balancing Authority shall submit the following data to the ERO annually by July 15: R2.1 The total annual net output of generating plants inside the Balancing Authority Area. R2.2 The total annual load with losses inside the Balancing Authority Area. R3. Each Balancing Authority shall calculate its Frequency Response Measure using Forms 1 and 2 as posted by the ERO. (See Attachment A_Form 1 and Form 2) R4. Each Balancing Authority or Frequency Response Sharing Group shall submit Forms 1 and 2 to contacts designated by the ERO before the expiration of ERO established deadlines, which shall be no earlier than 30 days after posting of Forms 1 and 2. R5. The ERO shall post the following information: R5.1. Each Interconnection's Frequency Response Obligation R5.2 Each Balancing Authorities Frequency Response Obligation R5.3 Each Balancing Authorities Frequency Bias Setting R6. Each Balancing Authority shall implement in its ACE equation its ERO established Frequency Bias Setting during the ERO established three-day implementation period. No further adjustments can be implemented outside of the parameters established below in the upcoming year unless a Balancing Authority coordinates with the Regional Entity and the affected Balancing Authorities. R6.1 A Balancing Authority using a fixed Frequency Bias Setting sets its Frequency Bias Setting to the greater of (in absolute value): R6.1.1. The number the BA chooses between 100% and 125% of its Frequency Response Measure as calculated on FRS Form 1. R6.1.2. The Balancing Authorities share of the Interconnection Minimum as determined by the ERO. R6.2 A Balancing Authority using a variable Frequency Bias Setting shall maintain a setting that is: R6.2.1 Less than zero at all times, and R6.2.2 Equal to or greater in magnitude than its Frequency Response Obligations when Frequency varies from 60 Hz by more than +/-0.036 Hz. R7. Each Frequency Response Sharing Group or Balancing Authority that is not a member of a FRSG shall monitor its Frequency Response Obligation and work with generating facilities or demand response resources to provide sufficient Frequency Response to meet the Frequency Response Obligation assigned by the ERO. R8. Each Balancing Authority that adds or removes generation or load, including through the

use of dynamic transfers, shall notify the ERO to ensure that any needed adjustments to the Interconnection Frequency Response Obligation or Balancing Authority Frequency Response Obligation and Bias can be calculated. R8.1. The ERO shall notify all affected Balancing Authorities of modifications to the Frequency Response Obligation due to the addition or removal of generation or load. R9. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent of the sum of the Frequency Bias Setting as communicated by the ERO for the participating Balancing Authorities.

No

It is our opinion that there has not been enough justification to merit creating a new standard. If additional justification is provided then frequency responsive reserves should be a subset of spinning reserves much like spinning reserves are a subset of operating reserves.

We are concerned with the tariff implictations associated with this standard. Will this standard create the need for an additional ancillary service under the FERC pro forma OATT?

Individual

Denise M Lietz

Puget Sound Energy

In reviewing the Consideration of Comments document, it is clear that the standard drafting team does not wish for the administrative elements of Attachment A to become items addressed during compliance evaluations (“There is no intent to require filing on a certain date and to have the BA prove to the auditor that a filing was made on that date.” This quote appears at several places in the Consideration of Comments documents, but first at page 113). However, because Attachment A is referenced in the standard, its provisions, including the timing table, are all mandatory and enforceable. This result is emphasized by the language of requirement R1, which states that entities “…shall achieve an annual Frequency Response Measure (FRM) as calculated and reported in accordance with Attachment A….” This language means that a failure to file a document on a date specified in the attachment would be a potential compliance violation. Because Attachment A is mandatory and enforceable, the standard drafting team should carefully review its provisions and clarify which elements are requirements and which elements are background statements or guidance. In addition, the use of additional headings and section numbers would add in clarifying the document (for example, at the top of page 3, there is a discussion of how an FRSG would calculate its FRM; however, there is an entire section beginning on page 4 addressing FRM where that discussion should instead appear).

No
See comment in response to question 4 above for a discussion of Attachment A concerns. Appendix 1 of the Frequency Response Standard Background Document contains a discussion about why the use of net actual interchange to calculate an entity's Frequency Response Measure might introduce inaccuracies into that calculation. That discussion ends with the following statement: "The frequency response is buried within the typical hour to hour operational cacophony superimposed on actual net interchange values. The choice of metrics will be important to artfully extract frequency response from the noise and other unrepresentative error." Based on these statements, it is very difficult to support the standard's approach to calculating the Frequency Response Measure. At Puget Sound Energy (PSE), though, we believe that there is another factor to add to the "operational cacophony" listed in Appendix 1. PSE is a comparatively small BA with limited internal generation. We are embedded between two of the largest energy exporters in the Western Interconnection and, when there is a frequency event, their response flows through PSE's system. As a result, PSE will experience transmission losses associated with the two BAs' frequency response as it flows through our system. When PSE's frequency response is measured using net actual interchange, these losses obscure, at least in part, our system's frequency response. As a result, we ask the standard drafting team to consider specifying a process that would allow us to propose and use an equivalent measure of frequency response. For example, while we understand the concerns and difficulties associated with measuring frequency response at the generator as the default measure for all BAs, in our case, a choice to use that measurement option might prove to be a more-feasible way to comply with the standard.
The definition of "Frequency Response Obligation" applies only to a Balancing Authority. However, requirement R1 applies to both FRSGs and BAs and includes a Frequency Response Obligation that applies to each of those entities. As a result, the definition must also address an FRSG's Frequency Response Obligation. The acronym for Balancing Authority is not included following the first reference to the term in requirement R1 (looks like an inadvertent deletion). Requirement R1 states that an entity "… shall achieve an annual Frequency Response Measure (FRM)…." However, the definition of Frequency Response Measure already includes the concept of annual. As a result, the word "annual" should be removed from the requirement. Requirement R1 includes the language "… to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation." This language is a purpose statement rather than a requirement applicable to a FRSG or a BA and should be excluded from the requirement. So long as an FRSG or BA achieves the FRM calculated in accordance with Attachment A, it has done everything necessary to comply with the standard. There are discrepancies between the implementation plan and the proposed standard: - The definitions of "Frequency Response Measure" and "Frequency Response Obligation" in the Implementation Plan are different from those proposed in the draft standard. - The Implementation Plan references "Reserve Sharing Group" rather than "Frequency Response Sharing Group". - The Implementation Plan does not include a definition for the term "Frequency Response Sharing Group". - The Implementation Plan continues to reference R5 in the discussion of the standard's proposed effective date. The annual process dates listed on page 32 of the Background document appear to be inconsistent with those listed in Attachment A.

While I support the concept of a Frequency Response Standard with minimum performance obligations, this Standard places the entire obligation for performance on the Balancing Authority (and Frequency Reserve Sharing Group). Requirements R2-R4 are properly assigned to the BA, as this is the entity that is responsible for the configuration and parameters in the ACE equation, including the provision of a frequency bias setting. Requirement 1, however, is a performance requirement over which the BA in the Functional Model has virtually no control or ability to influence. Only a Generator Owner or Generator Operator is in a position of control over the performance under this requirement through the operational control and configuration of the responding generating units. In most BA's, the host BA entity also owns a fair amount, even a vast majority in many cases, of the generation within the BA. However, even in the event that the host BA owned 100% of the generation within its metered boundary, it is the action of the entity exercising its GO/GOP function that impacts the frequency response performance within the Balancing Area. Assignment of R1 to the BA is inappropriate from the standpoint that reliability requirements are to be assigned to the Reliability Functions who are capable of causing compliance to occur. A BA has limited ability to influence the outcome of the R1 performance metric. This is unlike other BA-assigned requirements, such as those related to DCS or CPS compliance. For those, the BA does have considerable influence regarding the curtailment of transactions to restore ACE, the direction of plant loading so as to distribute operating reserve, etc. In contrast, performance under this proposed R1 of BAL-003-1 is dependent upon the actions of the GO/GOP in such things as governor settings, generator control system configuration and other operatinal or maintenance activities conducted at the generating plant site. For this reason, it is inappropriate to assign this performance requirement to the BA. Rather, the requirements should be allocated among the GO/GOP's of the on-line generation in some fashion. In further support of this notion, refer to the NERC Functional Model, where it is provided that one of the tasks for Generator Operation is to support Interconnection frequency.

I think it should be more clear or better defined that an interconnection does have some input into what events are selected.
No
I believe that the frequency bias obligation of the Western Interconnection is understated.
Yes
No
I feel that a BA's frequency bias for the upcoming year should not be related to present performance.

A BA may have a good response one year and not good response another year and therefore the threshold keeps moving around. I feel it should be related to BA size and therefore somewhat standardized. E.g. a high-performing Balancing Authority will have its frequency bias increased each year due to higher response during the events chosen by the ERO. Conversely, a low-performing Balancing Authority will have its frequency bias reduced each year due to lower response during the events chosen by the ERO.
This is an important task and the efforts of the drafting team are appreciated.

AESO
1. The AESO disagrees with using a non-authoritative background document that has definitions/description of terms used in the reliability standard. It is the opinion of the AESO that these definitions/descriptions need to be authoritative. 2. The AESO has previously submitted comments to the SDT that for the purpose of the FRM calculation, BAs should be able to exclude or include events based on specific conditions or consideration, such as data quality or event suitability (e.g. BA separation from the Interconnection). The revisions made by the SDT do not enable the inclusion of other relevant events in the FRM calcualtion by a BA. The AESO would like to to see these type of events to be permitted in the FRM calculation by a BA.

Additionally, there should be language to clarify that this is a negative value (the same should apply to the definitions of FRO and Frequency Bias). It is fairly obvious that these values should be negative when reading elsewhere in the proposed Standard and its related document but not in their definitions.
Yes
Additionally, there should be language to clarify that the BAs must belong to the same Interconnections to form the FRSG
Yes
BC Hydro applauds the STD's efforts to recognize a more suitable bound for Variable Frequency Bias settings
No
BC Hydro agrees with the principles outlined in the Attachment A but has some concerns as follows: 1.Attachment A is no longer recognized as one of the associated document of the proposed Standard

in its currently posted version. We believe this was removed by mistake. 2.There is no clarity as to how certain factors used in determining the Interconnection FRO such as CCADJ, CBR and BC'ADJ were determined. There is no apparent provision to re-assess any potential changes to these factors over the future years. If such provision is needed or has been provided then consideration should be given to averaging the adjustment over a longer duration (i.e., using the average of the factor observed over a number of years rather than just the year being assessed). 3.The method used for the allocation of the Interconnection FRO to BAs seems to not recognize the fact that frequency response from Load is much less than frequency response from Generation of an equal MW size. 4.If this Attachment A is considered an integral part of the standard then there should be some enforceable measures to ensure applicable entities adhering to the prescribed time line.
No
BC Hydro agrees in principle that the ERO should perform these tasks related to BAL-003-1 but has the following concerns: 1.There is no clear indication whether the Interconnection FRO will be calculated every year, and if yes, how each of the factors involved will be determined. 2.It is not clear whether data gathered in these procedures are only for the determination of annual FRO and FBS, or also to determine whether the BA or the FRSG was in compliance to BAL-003-1 for the assessed year. Since the ERO in this Document seems to be the NERC Resources Subcommittee and its Frequency Work Group, we think this fact should be made clear. The Background document should also be reviewed to ensure its alignment in this regard.
No Comment
Yes
BC Hydro respectfully submits these additional comments/observations: 1.The proposed standard seems to indicate that it is applicable to the identified responsible entities at all times. There might be circumstances where a BA that belongs to a multiple-BA Interconnection became isolated and has to operate in restorative mode which might require adjusting the frequency bias to a value less negative than the minimum FBS setting value in order to follow the much reduced load/generation level in the area. We suggest adding some language in either the Applicability section or in individual Requirements to recognize these circumstances. 2.Effective Dates: the proposed standard specifies a fixed period (12-month or 24-month) following Regulatory Approval which may fall in the middle of the year while the calculation and implementation are performed on an annual basis. Does this represent any conflicts? 3.The proposed standard does not clearly specify whether a BA must chose between using fixed bias or variable bias for the entire year. Should BAs be allowed to switched back and forth between the two methods? If yes, more details may be needed to account for the FRM and minimum FBS. 4.The proposed standard does not clearly specify whether a BA can be part of a FRSG for only part of the year or must be the whole year. 5.The definition of FRO, FRM, FBS, etc. should all include language to indicate the "negative" nature of the value. 6.Measure M2 should have "and uses a fixed bias" added for clarity purpose. 7.In the Additional Compliance Information section of the proposed standard the following info still exists: For Interconnections that are also Balancing Authorities, Tie Line Bias control and fFlat Ffrequency control are equivalent and either is acceptable. Since all reference to AGC Modes have been removed from the Requirements, this additional info should also be removed.

With a new process we are concerned that the interconnection minimum will initially move from 1.0% to 0.9%.

Yes
No
The drafting team should consider some method for discounting outliers, that may not be explainable.
No
In general we support the work of the DT, and the proposal to measure the systems response to frequency events, along with the method to determine the FRO. My outstanding concern is with enforcement on an entity that does not own the resources that provides the frequency response or the lack of obligation for the entity with the information to provide to the BA to make the assessment of expected frequency response. BA's should at a minimum be given assurance that resources will provide data that BA's could use to forecast frequency response and take corrective actions.

As a professionally trained published statistical expert never compensated by any balloting participant, I consider event selection criterion 7 to be unacceptable because it violates the fundamental statistical procedure of sampling statistical data "as is" and not pre-selecting the data (to fit some preferred even-distribution over time) and therefore biasing it before applying any statistical procedure to the data. Event criterion 6 is also unacceptable for being an an "ad hoc" explicit exclusion, from the definition of the frequency response being measured, of response to frequency events that occur during a specific kind of scheduled generation and load changes. Said exclusion needs to be written into the definition of the Frequency Response that is being measured. It is procedurally improper and unacceptable to bias the sampling procedure by explicit exclusion of data as an alternative to redefining the thing being sampled. In that case it's not generic Frequency Response that is being sampled, but some specific Frequency-Response-less-Response-to-Excluded-Events that is being measured. It is non-transparent and subterfuge to avoid instead accordingy reworking/narrowing the definition of Frequency Response, especially as said reworking requires a clear technical justification that is absent from this standard, and modifying the existing NERC Glossary definition of Frequency Response which Criterion 6 therefore stands in flat violation of.
No
This question is falsely worded. The SDT is specifically NOT using the method detailed in the Frequency Response Initiative Report dated September 30, 2012. So the term "this method" is practically meaningless in this question because it is not clear if it means "the SDT's method" or "the FRI's method". The Background Document specifically states on page 29: "The NERC Frequency Response Initiative Report addressed the relative merits of using the median versus linear regression for aggregating single event frequency response samples into a frequency response measurement score for compliance evaluation. This report provided 11 evaluation criteria as a basis for recommending the use of linear regression instead of the median for the frequency response measurement aggregation technique. The FRSDT made its own assessment on the basis of these evaluation criteria on September 20, 2012, but concluded that the median would be the best aggregation technique to use initially when the relative importance of each criterion was considered."

What needs to be changed, besides properly wording this question? The FRI method of linear regression should be adopted, and the SDT method of median should be rejected, in the standard to change the first sentence of this question into a true statement from a false statement and to, in answer to the question, provide for the proper amount of Frequency Response.
No
See reply to Question 6. Also, the Background Document is seriously deficient in the discussion of inertial response and therefore how imbalances "cause" frequency deviation. The Background Document is overflowing in discussion of how frequency deviation causes frequency response. In other words, the Background Document is "reactive" and not "proactive". The Background Document lacks any discussion of the internal dynamics of rotating machines, beginning with any definition of what Inertial Response is. Inertial Response is the instantaneous power produced by the lag ("inertia") in the ability of the generator's rotor to slow down to the frequency of the magnetic field in the generator's fixed stator whose frequency is instantaneously lowered by a change in phase angle between voltage and current that is due to a sudden loss of interconnected generation to meet load. Adjustments by voltage response within milliseconds and near the location of the loss are sometimes possible to avert rapid spread of a loss to the frequency of the entire interconnection, and constitute the ongoing work of the Phasor Project long ago initiated by the DOE in the persistent absence of NERC interest or work in this area. NERC and drafting team members under advisement by NERC staff studiously resisted so much as any mention of frequency deviation causation in discussions or in the Background Document. An inexplicable technical Cold War and Berlin Wall built in the 1970s and today separating the DOE Phasor Project from NERC Frequency Response standard development and NERC's so-called Frequency Response "Initiative" needs to be ended and torn down. My document http://www.robertblohm.com/Inertia.doc provides missing technical support and explanation for graphs 1-7 on pages 4-10 of the Background Document, on the basis of an exact understanding of Inertial Response.
A probabilistic/statistical basis needs to be developed for the FRM that assesses for usage of frequency response (causation of frequency error) and not just for provision of it. This would also overcome NERC's singular focus on reaction, and NERC's color-blindness to proaction, pointed out in my reply to question 7.

R1 places the burden for compliance on the BA but the BA does not control generation assets and should not be solely responsible for maintaining frequency response. While the standard can still define the amount of Frequency Response for each BA, there needs to be an obligation on the GO/GOP to provide that service as directed by the BA and they should also be held accountable for compliance. Finally, we do not believe that a sufficient study has been conducted to determine the impact of this standard. We are concerned that a substantial number of compliance issues could result and that the resulting cost to maintain compliance could be excessive and we suggest it be put

through the Cost Effective Analysis Process (CEAP). We suggest that the proposed values be evaluated on a sample size within each region to determine the number of compliance issues and for those issues that are found determine what the BA would have to do be compliant.

Spinning reserves are intended to support the interconnection response to the loss of a resource. If BAL-003-1 is adopted through this Project, the LADWP recommends that the spinning reserve requirements of BAL-002-0.1b and BAL-STD-002-0 be removed, as the Spinning reserve requirement would require utilities to reserve resources in excess of the reserves required in BAL-003-1. LADWP recognizes that this recommendation may be handled through a separate NERC Project, but wanted to submit this comment to bring light to this potential conflict in Reliability Standards.

Consideration of Comments

Project 2007-12 Frequency Response (BAL-003-1)

The Project 2007-12 Drafting Team thanks all commenters who submitted comments on the proposed standard, BAL-003-1 which was posted for a 30-day formal comment period from October 5, 2012 through November 6, 2012. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 50 sets of comments, including comments from approximately 144 different people from approximately 100 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

Based on industry comments the drafting team made the following clarifying modifications to the proposed standard and associated documents.

- Made clarifying changes to the proposed standard including replacing the term "…subject to…: with "…in accordance with…" in Requirement R2.
- Clarified the description of the calculation for the Interconnection IFRO in Attachment A.
- Modified Attachment A and the Procedure to provide consistency with the use of the term "resource contingency criteria".
- Corrected typographical errors in all documents.

All comments submitted may be reviewed in their original format on the standard's project page.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Mark Lauby, at 404-446-2560 or at mark.lauby@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_StandardsProcessesManual_20120131.pdf

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

If you support the comments submitted by another entity and would like to indicate you agree with their comments, please select "agree" below and enter the entity's name in the comment section (please provide the name of the organization, trade association, group, or committee, rather than the name of the individual submitter).

Summary Consideration:

Organization	Supporting Comments of "Entity Name"
MEAG Power	Southern Company Services, Inc - Gen
Associated Electric Cooperative, Inc. - JRO00088	SERC OC Standards Review Group
Avista	Bonneville Power Administration
Nebraska Public Power District	MRO NSRF [Midwest Reliability Organization - NERC Standards Review Forum]
ISO New England Inc.	Last submitted comments of ISO-NE which have not been addressed and, for efficiency sake, do not believe we should be requested to re-submit.
South Carolina Electric and Gas	SERC OC Standards Review Group
Entergy Services, Inc. (Transmission)	Entergy is in agreement with comments submitted by SERC on 11/5/0212.
Brazos Electric Power Cooperative, Inc.	ACES Power Marketing

1. The SDT has made minor modifications to the proposed definition for Frequency Response Measure based on industry comments. Do you agree that these modifications provide sufficient clarity? If not, please explain in the comment area.

Summary Consideration: A few of the commenters felt that the definition applied to all of the observations for both the BA and the FRSG. The drafting team stated that although they understood their concern they did not agree with them. They felt that the present definition provided sufficient clarity and decided to not make any modifications.

One commenter felt that the definition should state that it is a negative value. The drafting team explained that while the desired value would be negative it is mathematically feasible for the actual value to be positive but that value would by definition mean that the entity failed the measurement for Requirement R1.

Another commenter did not believe that there was sufficient clarity as to the number of observations that would be used to calculate FRM. The drafting team stated that the number of observations would vary from year to year. The basis for determining events is outlined in the Procedure attached to this standard.

Organization	Yes or No	Question 1 Comment
Duke Energy	No	The definition reads as if the FRM is the median of all of the observations reported by the Balancing Authorities and Frequency Response Sharing Groups. Duke Energy would suggest that the definition read, "The median of all of the Frequency Response observations reported annually by a Frequency Response Sharing Group, or Balancing Authority if not a participant in a Frequency Response Sharing Group, for frequency events specified by the ERO. The Frequency Response Measure is calculated as MW/0.1Hz."
Response: The drafting team thanks you for your comment. However, the drafting team believes that the present definition provides sufficient clarity and has decided to not make any changes.		
SERC OC Standards Review Group	No	The definition reads as if the FRM is the median of all of the observations reported by the Balancing Authorities and Frequency Response Sharing Groups. We agree with the Duke Energy suggestion that the definition read, "The median of all of the Frequency Response observations reported annually by a Frequency Response Sharing Group, or Balancing

Organization	Yes or No	Question 1 Comment
		Authority if not a participant in a Frequency Response Sharing Group, for frequency events specified by the ERO. The Frequency Response Measure is calculated as MW/0.1Hz."
Response: The drafting team thanks you for your comment. However, the drafting team believes that the present definition provides sufficient clarity and has decided to not make any changes.		
PPL NERC Registered Affiliates	No	The PPL Affiliates support the comments of the SERC OC Standards Review Group on this question.
Response: The drafting team thanks you for your comment. However, the drafting team believes that the present definition provides sufficient clarity and has decided to not make any changes.		
BC Hydro	Yes	Additionally, there should be language to clarify that this is a negative value (the same should apply to the definitions of FRO and Frequency Bias). It is fairly obvious that these values should be negative when reading elsewhere in the proposed Standard and its related document but not in their definitions.
Response: While the desired value would be negative it is mathematically feasible for the actual value to be positive but that value would by definition mean that the entity failed the measurement for Requirement R1.		
Tucson Electric Power	Yes	however, the number of observations to be used in calculating an entity's FRM is not clear.
Response: Thank you for your affirmative response and clarifying comment. The number of observations will vary from year to year. The basis for determining events is outlined in the Procedure attached to this standard.		
Exelon Corporation and its affiliates	Yes	Please see response to question 8. The FRM definition is acceptable within the context of the attachment description; however, without clarifying the terms under which the ERO specifies which events are to be measured, the FRM definition is too variable.
Response: Thank you for your affirmative response and clarifying comment. The criteria used to determine the events to be used are outlined in the Procedure attached to this standard. Please refer to our response to Question #8.		

Organization	Yes or No	Question 1 Comment
ACES Power Marketing Standards Collaborators	Yes	We believe that refinements to the definition were needed.
Response: Thank you for your affirmative response and clarifying comment.		
Manitoba Hydro	Yes	No comment.

Organization	Yes or No	Question 1 Comment
MISO	Yes	
American Electric Power		As provided in question 2 below, AEP does not agree with the definition containing the Frequency Response Sharing Group as this function does not exist at this point in time.
Response: Thank you for your comments. The term Frequency Response Sharing Group is defined at the beginning of the standard. Once this standard is approved by the industry, NERC BOT and FERC the definition will be removed from the standard and added to the NERC Glossary of Terms.		

2. The SDT has created a definition for Frequency Response Sharing Group. The definition is as follows: A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the Frequency Response Obligations of its members. Do you agree with this definition? If not, please explain in the comment area.

Summary Consideration: Almost all of the commenters wanted to modify the definition. The drafting team explained that they believed that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.

One commenter did not agree believe it was appropriate to define a new function that was not in the NERC ROP, NERC Statement of Registry Criteria or the NERC Functional Model. The drafting team stated that they had discussed this issue with NERC. NERC staff will add this entity to the registered entity list in the same manner as the existing Reserve Sharing Group. While this is not in the current version available online, NERC will have at least 24 months from the time of regulatory approval to add the entity to the list of registered entities.

Organization	Yes or No	Question 2 Comment
SERC OC Standards Review Group	No	A Balancing Authority may not be the entity maintaining or supplying resources, but would be responsible for utilizing applicable resources within its BA Area. We would modify the Duke Energy suggestion to read as follows: "A group whose members consist of two or more Balancing Authorities that collectively utilize operating resources with a goal to achieve a group FRM equal to or more negative than the sum of the Frequency Response Obligations of its members."
Response: Thank you for your comments. After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.		
American Electric Power	No	AEP does not necessarily disagree with the words of the definition. However, AEP does

Organization	Yes or No	Question 2 Comment
		not believe it is appropriate to define a new function that is not in the NERC Rules of Procedure, NERC Statement of Registry Criteria, or the NERC Functional Model. It is premature to incorporate this entity without a proposed change to these governing NERC documents.
Response: Thank you for your comments. The drafting team has discussed this issue with NERC. NERC staff will add this entity to the registered entity list in the same manner as the existing Reserve Sharing Group. While not in the current version available online, NERC will have at least 24 months from the time of regulatory approval to add the entity to the list of registered entities.		
Duke Energy	No	As a Balancing Authority may not be the entity maintaining or supplying resources, but would be responsible for utilizing applicable resources within its BA Area, Duke Energy would suggest the following definition, "A group whose members consist of two or more Balancing Authorities that collectively utilize operating resources required to achieve a group FRM equal to or more negative than the sum of the Frequency Response Obligations of its members."
Response: Thank you for your comments. After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.		
Edison Electric Institute	No	EEI does not fully agree with the definition of a "Frequency Response Sharing Group" (FRSG). In the definition offered in the new Standard, it states that the FRSG "collectively maintain, allocate, and supply operating resources". Of the three roles, a balancing authority only maintains load-interchange-generation balance through the allocation of resources. Therefore, EEI suggests that the definition be changed to more appropriately align with the role of a BA, which we believe would be to allocate resources in a manner that effectively allows the sharing of resources necessary to achieve a FRO within the defined sharing group, which might otherwise not be possible or practical by a BA on its own.
Response: After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This		

Organization	Yes or No	Question 2 Comment
will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.		
ACES Power Marketing Standards Collaborators	No	We agree that a definition is needed and thank the drafting team for writing one. However, we believe additional refinement of the definition is necessary. Although the definition appears to be written to parallel the Reserve Sharing Group definition, we think the definition needs to be simplified. For one, it encompasses actions that are not necessary. For instance, the proposed definition includes the action to "maintain operating resources". This could literally include generating plant maintenance. We do not agree that a Frequency Response Sharing Group would jointly perform maintenance on their plants. In fact, since the definition applies to BAs, it is entirely possible within the functional model that the BAs do not even own the plants and could not perform joint maintenance. We assume the purpose of including "maintain" was to recognize that maintenance of generating resources would need to be coordinated to ensure that there was sufficient frequency response reserve. We do not believe this needs to be explicitly identified in the definition. Furthermore, we find the use of "operating resource" as a source of potential confusion. While we understand operating resource is intended to mean a facility that provides the ability to increase or decrease MW output based on the frequency deviation, resource has various meanings throughout the standards and its use here could be confusing and contradictory. For instance, TOP-006-2 R1 discusses transmission resources. Furthermore, if an "operating resource" is capable of increasingor decreasing MW output based on frequency deviation, what is a "resource"? In other words, why is "operating" added to the term "resource"? We think it is best to avoid use of the term operating resource and, thus, recommend changing the definition to: "A group of two or more Balancing Authorities that share frequency response reserves and are required to jointly meet the Frequency Response Obligations of its members."
Response: After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.		
BC Hydro	Yes	Additionally, there should be language to clarify that the BAs must belong to the same

Organization	Yes or No	Question 2 Comment
		Interconnections to form the FRSG
Response: After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.		
PPL NERC Registered Affiliates	Yes	PPL Affiliates suggest additional detail be added to the definition to ensure the members of the FRSG are all within the same interconnection. The following definition includes the suggested changes: A group whose members consist of two or more Balancing Authorities all within a single interconnection that collectively operate resources required to jointly meet the sum of the Frequency Response Obligations of its members.
Response: After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.		
Ameren	Yes	The word "jointly" may add confusion and we believe it is unessassry.
Response: After review of suggested changes, the drafting team believes that the proposed definition should remain unchanged. The drafting team developed the definition to be essentially the same as that currently used for contingency Reserve Sharing Groups. This will help ensure that the different types of reserve groups are comparable as we move forward with this new type of group.

3. The SDT has added Requirement R3 for entities using variable Frequency Bias. R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is:

3.1 Less than zero at all times, and

3.3 Equal to or more negative than its Frequency Response Obligation when Frequency varies from 60 Hz by more than +/-0.036 Hz.

Summary Consideration: A couple of commenters felt that the intent of the requirement needed to be clarified. The drafting team explained that Requirement R3 is only applicable to a BA using a variable bias and does require a BA to maintain a bias less than zero. Bullet R3.2 extends the requirement to ensure that BAs using variable bias have a bias at least equal to the FRO when frequency is outside the bandwidth of +/- 0.036 Hz. The BAs using a fixed bias are addressed in Requirement R2.

A few commenters expressed concern with excluding a single BA interconnection from compliance with Requirement R3. The drafting team stated that they had discussed the applicability of variable bias requirements to single BA Interconnections extensively. The consensus of the drafting team was that single BA Interconnections inherently have strong incentives to accurately represent their frequency response characteristic. Any adverse consequences of misrepresenting the frequency response characteristic will be borne solely by that BA and cannot affect other BAs in other Interconnections adversely.

One commenter disagreed with allowing the use of variable Frequency Bias in a multi-BA interconnection. The drafting team believes that this concern may be better addressed within BAL-001. Variable frequency bias settings allow a Balancing Authority to better match their frequency bias setting in use with the actual frequency response occurring at any instant in time. If it is meeting its FRO for larger frequency deviations and the frequency bias setting in use at that time meets or exceeds its FRO, then the BA is doing its part to support frequency and AGC will not be withdrawing that frequency response.

Another commenter question the periodicity of a BA changing its Frequency Bias Setting to be considered using variable Frequency Bias. They gave an example of an entity changing its FBS monthly. The drafting team stated that they had not defined the periodicity for changing their bias to be variable. The example given would be a form of variable bias and would trigger all rules related to variable bias. Requirement R3 is separate from Requirement R4. Requirement R4 is related

to those entities providing Overlap Regulation Service. It is possible for an entity to provide Overlap Regulation Service and have a variable bias setting therefore an entity may be subject to compliance for both Requirement R3 and Requirement R4.

Organization	Yes or No	Question 3 Comment
American Electric Power	No	AEP believes this question in the comment form is incorrect. It appears that R3 and R4 are inadvertenly merged together.
Response: The drafting team is not sure of the point you are trying to make. The question only contains the Requirement R3 from the standard. The drafting team did notice that the numbering of the sub-bullets was incorrect.		
Duke Energy	No	Duke Energy agrees with allowing single-BA Interconnections to utilize a variable Frequency Bias Setting (FBS). Duke Energy disagrees with NERC allowing Balancing Authorities in a multiple-BA Interconnection to change the ACE and bounds by which the Balancing Authorities are measured under BAL-001 and BAL-002 by operating to a variable FBS. It is desired that a Balancing Authority be capable of recognizing the amount of primary response available in real-time operation, such information can be included among other information in the generation control algorithm; however, the obligation to support the Interconnection frequency under the secondary control standards, and the amount provided for any given frequency, should be based on the same criteria across all Balancing Authorities of the same size. Nathan Cohn in his comments on Union Electric's use of a variable FBS expressed similar concern regarding the equitable sharing of the obligation to support Interconnection frequency in a multiple-BA Interconnection. Take for example two Balancing Authorities with equal total generation and load, but one operating under a fixed FBS and the other operating under a variable FBS. To the extent that a Balancing Authority is not providing Frequency Response comparable to its fixed Frequency Bias Setting, its ACE will reflect the difference to be covered with secondary control and the Balancing Authority will be measured in a manner similar to other BAs of its "size" based upon the FBS. To the extent that the other BA using a variable FBS is not providing Frequency Response

Organization	Yes or No	Question 3 Comment
		comparable to what it would be allocated using a fixed FBS, its ACE will not reflect the difference or any further obligation to support Interconnection frequency at that time with secondary control. Duke Energy's concern regarding non-comparable treatment of all BAs is further amplified by the lack of scrutiny placed on the BA algorithm used to determine the real-time variable FBS, to ensure that compliance cannot be gamed by such use.
Response: The drafting team believes that this concern may be better addressed within BAL-001. Variable frequency bias settings allow a Balancing Authority to better match their frequency bias setting in use with the actual frequency response occurring at any instant in time. If it is meeting its FRO for larger frequency deviations and the frequency bias setting in use at that time meets or exceeds its FRO, then the BA is doing its part to support frequency and AGC will not be withdrawing that frequency response.		
Northeast Power Coordinating Council	No	If a BA is using a frequency bias setting and is not providing Overlap Regulation Service (supplying actual interchange, frequency response, and schedules to another BA), then it can be assumed that the BA is supplying regulation service. Was the intent of the requirement to simply state that all BA's must have a bias setting less than zero at all times? The intent of this requirement needs to be clarified.
Response: The drafting team is not sure if we understand your first comment. A BA not providing Overlap Regulation Service may or may not be providing Supplemental Regulation Service. Requirement R3 is only applicable to a BA using a variable bias and does require a BA to maintain a bias less than zero. Bullet R3.2 extends the requirement to ensure that BAs using variable bias have a bias at least equal to the FRO when frequency is outside the bandwidth of +/- 0.036 Hz. The BAs using a fixed bias are addressed in Requirement R2.		
Consolidated Edison Co. of NY, Inc.	No	If a BA is using a frequency bias setting and is not providing Overlap Regulation Service (supplying actual interchange, frequency response, and schedules to another BA), then we can assume it is supplying regulation service. Was the intent of the requirement to simply state that all BA's must have a bias setting less than zero at all times? Please clarify the intent of this requirement.
Response: The drafting team is not sure if we understand your first comment. A BA not providing Overlap Regulation Service may or may not be providing Supplemental Regulation Service. Requirement R3 is only applicable to a BA using a variable bias and		

Organization	Yes or No	Question 3 Comment
does require a BA to maintain a bias less than zero. Bullet R3.2 extends the requirement to ensure that BAs using variable bias have a bias at least equal to the FRO when frequency is outside the bandwidth of +/- 0.036 Hz. The BAs using a fixed bias are addressed in Requirement R2.		
Exelon Corporation and its affiliates	No	Please see response to question 8.
Response: Please refer to the drafting team response to Question #8.		
MRO NSRF	No	The MRO NSRF is concerned with the drafting team's exclusion of single Balancing Authority Interconnections from compliance with Requirement R3. To ensure a consistent approach in the application of the standard, recommend R3 be revised as follows:(R3). Each Balancing Authority that is not receiving Overlap Regulation Service and is utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is: ...
Response: The drafting team discussed the applicability of variable bias requirements to single BA Interconnections extensively. The consensus of the drafting team was that single BA Interconnections inherently have strong incentives to accurately represent their frequency response characteristic. Any adverse consequences of misrepresenting the frequency response characteristic will be borne solely by that BA and cannot affect other BAs in other Interconnections adversely.		
MISO	No	We agree with the general obligation but believe that the requirement should apply to single BA Interconnections as well. This is supposed to be a North American standard. What other standards shouldn't apply to a single BA Interconnection? We have the same concern with Requirement 2.
Response: The drafting team discussed the applicability of variable bias requirements to single BA Interconnections extensively. The consensus of the drafting team was that single BA Interconnections inherently have strong incentives to accurately represent their frequency response characteristic. Any adverse consequences of misrepresenting the frequency response characteristic will be borne solely by that BA and cannot affect other BAs in other Interconnections adversely.		
PJM Interconnection, LLC	No	With what periodicity does a BA's frequency bias setting have to change to be

Organization	Yes or No	Question 3 Comment
		considered variable bias? For example, if a BA changes it's frequency bias setting monthly based on a percentage of each month's forecast or historic load, is this considered variable bias subject to compliance with R3 in lieu of R4?
Response: The drafting team has not defined the periodicity for changing their bias to be variable. The example given would be a form of variable bias and would trigger all rules related to variable bias. Requirement R3 is separate from Requirement R4. Requirement R4 is related to those entities providing Overlap Regulation Service. It is possible for an entity to provide Overlap Regulation Service and have a variable bias setting therefore an entity may be subject to compliance for both Requirement R3 and Requirement R4.		
BC Hydro	Yes	BC Hydro applauds the STD's efforts to recognize a more suitable bound for Variable Frequency Bias settings
Response: Thank you for your affirmative response and clarifying comment.		
Bonneville Power Administration	Yes	BPA is responding to 3.1 and 3.2 of R3. The bullets listed in question 3 on the original comment form appear to be for Requirement R4. BPA is in support of R3.1 and R3.2.
Response: Thank you for your affirmative response and clarifying comment.		
Texas Reliability Entity	Yes	It appears that R3.2 is based on the assumption that governor dead-band settings are 0.036 Hz for all interconnections with multiple BAs. While the ERCOT region has a standard 0.036 Hz dead-band specified in the ERCOT Protocols and Operating Guides, we are not sure if this is applicable to the other regions.
Response: Thank you for your affirmative response and clarifying comment. In addition, as to the deadband setting, this number was also considered to be within the frequency deviation range of the event determination criteria as defined in the Procedure document.

4. Based on Industry comments the SDT has modified "Attachment A- Supporting Document" to provide additional clarity. Do you agree with the modifications? If not, what modifications do you disagree with?

Summary Consideration: A few commenters felt that there were requirements stated within Attachment A. The drafting team explained that the requirement stated in the standard was the only requirement related to FRM. Attachment A is there to provide uniformity in the calculation of the FRM. The drafting team conscientiously included only reliability objectives in the requirements and put procedural steps in the attachment and procedure.

Several commenters expressed concern over the use of the largest event in the last 10 years for the Eastern Interconnection while all of the other Interconnections used the Category C (N-2). The drafting team stated that the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details are provided on pages 52 through 55 of the Frequency Response Initiative paper.

A couple of commenters questioned the difference between the present frequency bias of -6,360 MW/0.1 Hz and the proposed of -1,002 MW/0.1 Hz. The drafting team explained that the -6,630 MW/0.1 Hz represents a summation of the Frequency Bias Settings of all Balancing Authorities in the Eastern Interconnection, most of which use the 1% default minimum as required in the current BAL-003-0 standard, which far exceeds their real response. The IFRO of -1002 MW/0.1 Hz is the response determined to avoid the first step of Underfrequency load shedding in the Interconnection for a 4,500 MW generation loss.

A few commenters felt that clarification was need concerning changes in a BAs footprint and changes to the bias setting or FRO. The drafting team felt that this was a problem that would take care of itself. If two BAs change footprint but do not raise the issue the impact is transparent to the Interconnection. If one BA believes that its limits need to be adjusted the process will adjust the limits of both BAs accordingly.

A couple of commenters requested clarity as to how changes to the process in Attachment A would be handled. The drafting team explained that any change to the methodology described in Attachment A would have to go through the Standards Development Process prior to being implemented.

Two commenters felt that there should be an exemption for non-conforming load performing contrary to the performance of conventional load. The drafting team stated that they did not agree that there should be an exemption but has designed the forms to allow for adjustments for non-conforming load. However the BA may find that no adjustment for non-conforming load may be needed due to the measurement over multiple events rather than individual events.

Organization	Yes or No	Question 4 Comment
ACES Power Marketing Standards Collaborators	No	**(1)** Frequency Response Obligation (FRO) is used inconsistently with the proposed definition in the document. The document uses the term "Interconnection Frequency Response Obligation" in many locations. However, FRO specifically is defined as the BA's "share of the required Frequency Response". It does not apply to the Interconnection. How can the Interconnection have a share of the required frequency response? A new term may need to be defined for the Interconnection required Frequency Response. **(2)** On page 3 Attachment A states the ERO will post the Frequency Bias Setting for each BA along with their Frequency Response Obligation. Later on the same page, the document states that the BA shall set its Frequency Bias Setting to 100% to 125% of it Frequency Response Measure or Interconnection Minimum. What is the purpose of the ERO determining Frequency Bias Settings if the settings are not going to be used by the BA? What are we missing in the explanation? **(3)** Late on page 3, the document states that BAs are encouraged to notify NERC if load or generation is transferred. Section 4(a) on page 8 of the Rules of Procedure Appendix 5A - Organization Registration and Certification Manual indicates that changes to a Registered Entity's footprint actually triggers a potential certification audit. Since BAs are required to be certified and moving generation or load from the metered boundaries of one BA to another BA would represent a change in footprint, we suggest removing the word "encouraged" and stating affirmatively that BAs must notify NERC of such changes and referencing the appropriate section of the Rules of Procedure. Otherwise, BAs may not realize notification is actually required.
Response: (1) The drafting team believes the IFRO and FRO terms are used appropriately in Attachment A. Interconnection Frequency Response Obligation is not defined in the standard nor is it a performance obligation. The drafting team has clarified Attachment A in instances when using the terms to address your comments.		

Organization	Yes or No	Question 4 Comment
(2) The ERO is not determining the FBS but is only validating the FBS provided by the BA on FRS Form 1. **(3) The SDT believes these are two coordinated but separate processes. If the Rules of Procedure apply, as worded this document provides the avenue to make the necessary changes to Frequency Bias Setting.**		
Consolidated Edison Co. of NY, Inc.	No	**(1)** This document lacks definitions of terms such as CCadj, DFcc, DFcbr, resource contingency criteria (in the attachment, this is called the "target contingency criteria"), etc. **(2)** Of value to entities would be a sample calculation. **(3)** "The largest category C (N-2) event is used for all interconnections except the Eastern which uses the largest event in the last 10 years". Why aren't all interconnections using the same design contingency design basis? **(4)** The NERC 2012 CPS2 bounds has an Eastern Interconnection frequency bias of -6,360 MW/.1Hz. Can the DT explain why this attachment refers to an Interconnection frequency response obligation of -1,002MW/.1Hz. This is a significant difference.
Response: (1) As stated in Attachment A these terms are defined in the Procedure. The drafting team clarified the use of multiple terms of "resource contingency criteria" throughout both Attachment A and the Procedure documents. **(2) The drafting team will provide a sample calculation of the BA FRO and FRM and post this information on the NERC RS website. The calculation of the IFRO is shown in the Attachment A with the formulas shown in the Procedure document.** **(3) The results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details are provided on pages 52 through 55 of the Frequency Response Initiative paper.** **(4) The -6,630 MW/0.1 Hz represents a summation of the Frequency Bias Settings of all Balancing Authorities in the Eastern Interconnection, most of which use the 1% default minimum as required in the current BAL-003-0 standard, which far exceeds their real response. The IFRO of -1002 MW/0.1 Hz is the response determined to avoid the first step of Underfrequency load shedding in the Interconnection for a 4,500 MW generation loss.**		

Organization	Yes or No	Question 4 Comment
American Electric Power	No	AEP is under the impression that there are some requirements, which though not explicitly stated, are implied in Attachment A. AEP feels strongly that these "sub-requirements" should be clarified and contained within the body of the requirements of the standard.
Response: The requirement stated in the standard is the only requirement related to FRM. Attachment A is there to provide uniformity in the calculation of the FRM.		
Duke Energy	No	As indicated in our comments in the past, Duke Energy is certain that as the Interconnection Frequency Bias Setting (FBS) is set closer to the actual Frequency Response in a multi-BA Interconnection, most BAs will be challenged in meeting CPS2, while CPS1 and the proposed Balancing Authority ACE Limit (BAAL) will be more achieveable bounds, and in some cases CPS1 performance will improve. Though probably most of the BAs may welcome a FBS set as high in magnitude as allowed to address the potential compliance risk, there are some which may desire to set their FBS closer to their required minimum allocation rather than have to take on a larger obligation in frequency support under the secondary control measures. Duke Energy believes that this proposed standard should incent BAs to provide more than their share of Frequency Response to the Interconnection and allow that good performance to be recognized; however the requirements described in Attachment A for determining the minimum Frequency Bias Setting (FBS), which requires that the FBS be set no lower in magnitude than the FRM, will leave certain over-performing BAs with no choice but to reduce their actual Frequency Response (still well-above their FRO) if they want to operate with a FBS set closer to the Interconnection Minimum allocation and be relieved of the associated increased obligation for frequency support under the secondary control measures. The FBS is embedded within the secondary control measures of CPS1, CPS2 and the draft Balancing Authority ACE Limit (BAAL). Comparable treatment of similarly-sized BAs (based upon the FRO allocation) is only possible if all BAs are provided the same minimum FBS requirement. To the extent that a BA provides more than its share of response to events, it's over-performance will only

Organization	Yes or No	Question 4 Comment
		be recognized if its ACE is allowed to reflect a FBS comparable to its peers, allowing its over-performance to be reflected in ACE in support of bringing frequency closer to 60 Hz. Generation control algorithms implemented today to optimize CPS1 will allow non-zero ACE when in support Interconnection frequency within bounds determined by the BA - there should be no concern of "response withdrawal" with such algorithms in place, the BA will simply get credit for such performance. As depicted in the current document, the over-performing BA would be required to set its minimum FBS at its FRM (or greater in magnitude), taking away what should be considered over-performance, erasing it in ACE, and turning it into an obligation under the secondary control measures. Based upon the draft, the only way that the BA could be treated comparably to other similarly sized BAs held only to operating to the Interconnection Minimum allocation, would be to reduce its actual response in FRM to a value less in magnitude than its Interconnection Minimum allocation. Duke Energy believes that BAs should be incented to provide more than their share of Frequency Response, and be given the opportunity to report performance on a basis comparable to similar-sized BAs. Our opinion is that Attachment A ensures that the Interconnection Frequency Bias Setting will remain at some margin above the actual Interconnection Frequency Response in magnitude - the reliability of the Interconnection will not be at risk by allowing over-performing BAs to operate and report performance on a comparable basis to other similarly-sized BAs based upon the Interconnection Minimum allocation if they choose to do so - to that extent, Duke Energy suggests that the language on page 3 be changed to:"A BA using a fixed Frequency Bias Setting may set its Frequency Bias Setting to any number the BA chooses up to 125% of its Frequency Response Measure as calculated on FRS Form 1, but no less in magnitude than its Interconnection Minimum allocation as determined by the ERO."Regarding the argument which could be offered that a larger FBS in magnitude will also allow wider bounds for control performance, Duke Energy agrees that a large portion of the BA operation will be around 60 Hz where such a benefit could be realized, however it would also come at the cost of a larger obligation than other comparably-sized BAs in sustained support of frequency during the more critical times of significant deviation from 60 Hz where the BA's compliance could be at risk. Below 59.95 Hz in the Eastern Interconnection (the

Organization	Yes or No	Question 4 Comment
		Frequency Trigger Limit under BAAL), the additional MWs needed to be compliant for any given frequency are greater than the MWs of imbalance allowed by the larger BAAL bound - comparably-sized BAs will not be comparably judged if the standard forces over-performing BAs to assume a larger FBS (in magnitude) than their peers - that should be the decision of the BA. We believe that the proposed language above will create the proper incentive for a Balancing Authority to provide more than its minimum allocation of Frequency Response, and allow it to choose if it wants to make that performance part of a larger FBS (in magnitude), knowing the associated risks and benefits of that decision.Duke Energy supports this standard allowing for Frequency Response Sharing Groups, however the requirements and supporting documents need to clearly allow the FRSG to be treated no differently than if it was a Balancing Authority and shield the participating BAs from compliance scrutiny when all scrutiny should be placed on the FRSG performance as a whole. At the top of Page 3, the standard attachment allows the FRSG to "calculate a group NIA and measure the group response to all events in the reporting year on a single FRS Form 1", however at the bottom of page 3, the standard attachment still requires the FRSG BAs to individually fill out Form 1 and Form 2 for the purposes of determining the minimum Frequency Bias Setting. Duke Energy believes that the standard language in Attachment A, and the supporting form(s), should allow the FRSG, if it chooses, to also report the split of the group FRM which the BAs will use to individually determine their Frequency Bias Setting, rather than require each BA in an FRSG to still maintain Form 1 and Form 2 data. Form 1 could be modified for the FRSG to report the group's FRM along with the split of the FRM among the members, and another form could be developed for each FRSG BA to fill out, replicating only the section of Form 1 (column S) where each BA could provide values for its FRM allocation, its desired FBS, its minimum FBS allocation, and so on.
Response: The drafting team has chosen to reduce the minimum Frequency Bias Settings for individual BAs on a controlled basis on each Interconnection. Your suggestion would eliminate the ability of the drafting team to coordinate the reduction of the minimum Frequency Bias Settings for the BAs. Other commenters have stated that they disagree with reducing the minimum		

Organization	Yes or No	Question 4 Comment
Frequency Bias Setting. The drafting team is attempting to balance between the two positions stated in previous postings. **The drafting team understands your concern regarding the treatment of FRSG and the minimum Frequency Bias Setting. However, the drafting team believes that this allocation of Frequency Bias among the FRSG members on a basis different from the measured response could be detrimental to reliability under system separation conditions. Future consideration of this issue may be possible once additional information is available.**		
Independent Electricity System Operator	No	As indicated in our previous comments, the status of Attachment A is unclear. It is a mixture of requirements, criteria, process and guideline. Making a direct reference in the standard's requirements (R1 and R2) makes Attachment A as part of the requirement and hence is enforceable, but it contains process and guideline information that is not subject to assessment. On the other hand, the absence of a Measure to assess adherence to the criteria and process suggests that Attachment A is not enforceable. It is this ambiguity that makes it difficult for the industry to assess the extent to which they must follow the process. Again, we urge the SDT to keep only the criteria/process parts that must be adhered to in Attachment A, and extract the remaining parts and place them in a guideline document, or an appendix.In addition, the Responsible Entities are required to submit Form 1 and Form 2, but such requirements are not written explicitly as "shall", and are imbedded in the Attachement whose mandatory status is unclear. This makes the standard very confusing from an Responsible Entity's obligation and compliance perspective.
Response: The requirement stated in the standard is the only requirement related to FRM. Attachment A is there to provide uniformity in the calculation of the FRM. The drafting team conscientiously included only reliability objectives in the requirements and put procedural steps in the attachment and procedure.		
BC Hydro	No	BC Hydro agrees with the principles outlined in the Attachment A but has some concerns as follows: 1.Attachment A is no longer recognized as one of the associated document of the proposed Standard in its currently posted version. We believe this was removed by mistake.

Organization	Yes or No	Question 4 Comment
		2.There is no clarity as to how certain factors used in determining the Interconnection FRO such as CCADJ, CBR and BC'ADJ were determined. There is no apparent provision to re-assess any potential changes to these factors over the future years. If such provision is needed or has been provided then consideration should be given to averaging the adjustment over a longer duration (i.e., using the average of the factor observed over a number of years rather than just the year being assessed). 3.The method used for the allocation of the Interconnection FRO to BAs seems to not recognize the fact that frequency response from Load is much less than frequency response from Generation of an equal MW size. 4.If this Attachment A is considered an integral part of the standard then there should be some enforceable measures to ensure applicable entities adhering to the prescribed time line.
Response: **(1) The drafting team disagrees that Attachment A is not one of the associated documents of the standard. It is included by reference in Requirements R1 and R2 and will be attached to the standard upon final approval.** **(2) If the data inputs change then the number will change but the methodology used to calculate the number cannot change without going through the standards process.** **(3) The drafting team agrees with your conclusion. The source of the Frequency Response is not related to the distribution of the obligation.** **(4) The requirement stated in the standard is the only requirement related to FRM. Attachment A is there to provide uniformity in the calculation of the FRM. The drafting team conscientiously included only reliability objectives in the requirements and put procedural steps in the attachment and procedure.**		
Bonneville Power Administration	No	BPA does not agree with the methodology in Attachment A. Please see BPA's response to question 6 as well as BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf.

Organization	Yes or No	Question 4 Comment
Response: Please refer to our response to Question #6 and our responses to your comments submitted on 12/8/11.		
Exelon Corporation and its affiliates	No	Exelon is troubled by the approach of having requirements that rely so heavily on the attachment to the standard. The use of both of the documents is required to be compliant and this makes it difficult to determine what the obligations are and increases the chance for error in interpretation. The suggested changes below in response to question 8 take information from the Attachment and establish requirements so that an entity does not have to go back and forth between the two documents to identify its obligations. Attachment A should then be modified to include examples of Forms 1 and 2 and instructions for completing the form for Balancing Authorities and Frequency Response Sharing Groups.
Response: The requirement stated in the standard is the only requirement related to FRM. Attachment A is there to provide uniformity in the calculation of the FRM. The drafting team conscientiously included only reliability objectives in the requirements and put procedural steps in the attachment and procedure. **The drafting team will provide a sample calculation of the BA FRO and FRM and post this information on the NERC RS website. The calculation of the IFRO is shown in the Attachment A with the formulas shown in the Procedure document.**		
SERC OC Standards Review Group	No	It is important for NERC to monitor the interaction between the deployment of this standard and its impact on CPS1, CPS2, and BAAL. If performance in the CPS criteria is degraded, there should be a halt in the reduction of the minimum bias setting allowed. There is also concern that we are providing the correct incentives to the entities to provide the appropriate amount of frequency response. We also suggest that clarification be made so that changes in the BA's footprint that would necessitate changes in the bias setting or the FRO be permanent changes, not just temporary. It is unclear how performance would be measured for a BA versus a frequency response sharing group.

Organization	Yes or No	Question 4 Comment
Response: The minimum is not required to be reduced but is allowed to be reduced if no significant impacts are seen on CPS1, CPS2 and BAAL. **The drafting team agrees that temporary changes will not apply in this case. It is a problem that will take care of itself. If two BAs change footprint but do not raise the issue the impact is transparent to the Interconnection. If one BA believes that its limits need to be adjusted the process will adjust the limits of both BAs accordingly.** **The Background Document and Attachment A explain how a FRSG would report. The FRS Forms allow BAs and RSGs to account for contributions from either.**		
PPL NERC Registered Affiliates	No	The NERC posting did not include a redline to Attachment A, therefore, it is not clear what modifications were made. However, there are several modifications that would add clarity to the attachment. The PPL Affiliates support the comments of the SERC OC Standards Review Group on this question, additionally, the following issues should be addressed: In Attachment A, page 3 and elsewhere, clarify that temporary or small transfers of load or generation between BAs do not require notification to the ERO or changes to the FBS or CPS limits. In Attachment A, page 4, a BA should be allowed to be exempt from evaluation any single frequency event where non-conforming load performs contrary to the performance of conventional load (ie. during a frequency decline, the non-conforming load simultaneously increases significantly). By nature, non-conforming load is totally unpredictable, changes quickly, and fluctuates widely. Other than interruption, the BA has no control over the actions of such loads nor can the BA predict or assume any "normal" action by a non-conforming load during a frequency disturbance event. Setting a limit on the number of events that a BA could exempt (regardless of the reason) from FR evaluation in any given year would be more fair and effective in evaluating a BA's frequency response performance.
Response: Please refer to our response to the SERC OC Standards Review Group.		

Organization	Yes or No	Question 4 Comment
The drafting team does not agree that there should be an exemption but has designed the forms to allow for adjustments for non-conforming load. However the BA may find that no adjustment for non-conforming load may be needed due to the measurement over multiple events rather than individual events.		
Kansas City Power & Light	No	The Standard proposes a calculation that overstates the frequency response obligation (FRO) for Balancing Authorities.
Response: The drafting team disagrees with your comment. However, the drafting team cannot provide any detail due to the lack of details in your comment.		
Arizona Public Service Company	No	The supporting document on the standards page does not provide information on CB Ratio and why it is used. It significantly increases FRO and should be justified based upon strong technical basis and actual experience. (Please also see AZPS response to question 6, The Frequency Response Initiative Report should be on the Standards page).
Response: The rationale can be found beginning on page 14 of the Background document and page 49 of the FRI report. **Please refer to our response for Question #6.**		
PJM Interconnection, LLC	No	The target contingency protection criterion for the Eastern Interconnection is the largest event in the last 10 years (believed to be a 2007 event) which is inconsistent with the other Interconnections. Is periodic review required for this criteria? Will this criteria be revised after the referenced event is older than 10 years? Are the other three interconnection's target contingency protection criteria subject to revision if they experience an event larger than a category C? This BA believes that future periodic analysis should be defined and subsequent findings used to support changes via the standard revision process. What are the procedural requirements for revising Attachment A? This BA is concerned that the procedure for revising Attachment A is undefined and

Organization	Yes or No	Question 4 Comment
		that, for example, the IFRO could be increased absent the formal standard revision process, increasing a BA's FRO and subsequently increasing a BA's compliance risk without providing BA's the opportunity to review, comment, and ballot.Related to the previous comment/question, how often are the statistically derived values in Table 1 subject to a required update? For example, the Eastern Interconnection is adjusted due to observed primary frequency response withdrawal ('lazy L' characteristic). The other Interconnections are adjusted for observed differences between point C and point B. As the frequency response characteristics of any Interconnection change, is Table 1 subject to required analysis and revision? This BA believes that future periodic analysis should be defined and subsequent findings used to support changes via the standard revision process. Attachment A indicates that a BA may exclude an event from annual Form 1 FRM evaluation only if its tie-line or frequency data is corrupt or unavailable. This exempts numerous scenarios that could result in a poor response score due to system variations. These could include, but are not limited to, changing energy schedules, changes in load, and AGC driving units up or down due to the ACE value at the time of the frequency event. This subjects the BA to undue compliance risk even though the BA may have adequate frequency responsive resources at the time. This BA suggests that the FRSDT adopt language (and Form 2 functionality) that allows the exclusion of events that are skewed by these types of situations. Attachment A and Forms 1 & 2 specify that 20 to 52 seconds will be used as the post-event B point average for FRM determination. The number of fast responding resources will increase as the technology for batteries, flywheels, and frequency controlled demand side devices moves forward over time. The 20 to 52 second interval does not adequately incentivize the devopment of these technologies.
Response: The results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason, the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details		

Organization	Yes or No	Question 4 Comment
are provided on pages 52 through 55 of the Frequency Response Initiative paper. **As the model for the EI is improved and information and experience is gained under this standard the answer to your question will be determined through an open and inclusive process.** **If it is determined that a change in any methodology used in the processes in this standard is needed it would have to go through the standards process.** **The drafting team does not agree that there should be an exemption but has designed the forms to allow for certain adjustments. In addition, the methodology recommended utilizing the median addresses the concerns related to a single event occurrence. Ultimately the BA may find that no adjustment may be needed due to the measurement over multiple events rather than individual events.** **This standard was not intended to provide incentives for the development of new technologies. It is intended to provide for the reliable operation of the Bulk Electric System.**		
Northeast Power Coordinating Council	No	This document lacks definitions of terms such as CCadj, DFcc, DFcbr, resource contingency criteria (in the attachment, this is called the "target contingency criteria"), etc. A sample calculation would be of value to entities. "The largest category C (N-2) event is used for all interconnections except the Eastern which uses the largest event in the last 10 years". All interconnections should be using the same design basis contingency. The NERC 2012 CPS2 bounds has an Eastern Interconnection frequency bias of -6,360 MW/.1Hz. Why does this attachment refer to an Interconnection frequency response obligation of -1,002MW/.1Hz.? This is a significant difference.
Response: As stated in Attachment A these terms are defined in the Procedure. The drafting team clarified the use of multiple terms of "resource contingency criteria" throughout both Attachment A and the Procedure documents. **The drafting team will provide a sample calculation of the BA FRO and FRM and post this information on the NERC RS website. The calculation of the IFRO is shown in the Attachment A with the formulas shown in the Procedure document.** **The results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason, the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details are provided on pages**		

Organization	Yes or No	Question 4 Comment
52 through 55 of the Frequency Response Initiative paper. **The -6,630 MW/0.1 Hz represents a summation of the Frequency Bias Settings of all Balancing Authorities in the Eastern Interconnection, most of which use the 1% default minimum as required in the current BAL-003-0 standard, which far exceeds their real response. The IFRO of -1002 MW/0.1 Hz is the response determined to avoid the first step of Underfrequency load shedding in the Interconnection for a 4,500 MW generation loss.**		
Ameren	No	We disagree on having different methodologies for determining the targets, and would like clarity added for when those targets may change, such as what will happen after the largestest event in the last 10 years rolls off the books for the EI?
Response: The results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason, the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details are provided on pages 52 through 55 of the Frequency Response Initiative paper. **If it is determined that a change in any methodology used in the processes in this standard is needed it would have to go through the standards process.** **As the model for the EI is improved and information and experience is gained under this standard the answer to your question will be determined through an open and inclusive process.**		
Manitoba Hydro	Yes	(1) Page 2, Balancing Authority Frequency Response Obligation (FRO) and Frequency Bias Setting: States that the ERO is responsible for "annually assigning an FRO and Frequency Bias Setting to each BA." No mention is made of FRSGs. (2) Neither R1 nor the referenced Attachment A clarifies the FRM requirements for an FRSG to comply versus a BA. In particular, compared to BAL-002-0 R1.1, which clearly states that the BA may elect to fulfill its obligation through an FRSG and that in such cases the FRSG has the same responsibilities as each BA (that is a participant in the FRSG). (3)Attachment A refers to an FRSG calculating FRM, but the standard does not.

Organization	Yes or No	Question 4 Comment
Response: 1) - The FRSG FRO is a summation of its members' FROs. **2) & 3) -The drafting team believes that it is clearly stated for a FRSG compliance with R1. The Requirement reads "Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation."**		
Texas Reliability Entity	Yes	1. The calculation for the FRO for ERCOT includes a credit of 1400 MW for load resources. 1400 MW is currently the maximum amount of LR that can be procured through the ERCOT ancillary service process. There can be periods during the day where 1400 MW was not procured or is not available (It was noted during the summer of 2012 that on some days, only 900 MW of LR was available through the ancillary service process). Should the calculated IFRO (-286 MW per 0.1 Hz) be modified to account for this variation? 2. Background Document says: "Attachment A proposes the following Interconnection event criteria as a basis to determine an Interconnection's Frequency Response Obligation: o Largest category C loss-of-resource (N-2) event o Largest total generating plant with common voltage switchyard o Largest loss of generation in the interconnection in the last 10 years" For ERCOT, the largest loss of generation in the last 10 years was over 3400 MW, and does not match the 2750 MW (N-2) value used for the IFRO calculation.
Response: **(1) The process used to determine the IFRO has been vetted through multiple forums. The drafting team feels that the proposed calculation is appropriate for the standard at this time. As experience is gained through the implementation of this standard, the calculation will be reviewed and any adjustments will be addressed through an open and inclusive process.** **(2) The results for the current Texas Interconnection model represent observed response adequately so the recommended Resource Contingency Criteria for ERCOT is the Category C N-2 event. For further details related to the full determination,**		

Organization	Yes or No	Question 4 Comment
please refer to the Frequency Response Initiative paper.		
SPP Standards REview Group	Yes	Delete the 2nd 'that' in the 2nd bullet at the top of page 3.
Response: Thank you for the comment. The drafting team has made the correction.		
Xcel Energy	Yes	It is not clear however, as to if this is actually part of the standard or if it is a document that can be revised without going through the standards development process. Also, the formatting of the document should be modified to clearly identify where 'steps/actions' are needed from responsible parties, whether that be the ERO or BA/FRSG.
Response: If it is determined that a change in any methodology used in the processes in this standard is needed it would have to go through the standards process. **Please refer to the "timeline" on page #6 of Attachment A as this clearly provides for who has responsibility for each step in the process.**		
NextEra Energy	Yes	NextEra Energy does not support the changes made. It is concerned that certian changes were made to help some large East coast entities that could not comply at the expense of the FRCC region. Specifically, now on page 3 of Attachment A 4th paragraph from the bottom the statement is made " sets its frequency bias to the greater of". We believe that this must be changed to either Statement 1 " Any number the BA chooses between 100% etc"Or Statement 2 " Interconnection minimum as determined by the ERO" Without this change, NextEra beleives the FRCC will be unfiarly treated relative to others on the Eastern Interconnection. The technical reasons for this is concern was explained during the Standard Drafting Team meetings. In addition, the ERO limit which is set at 0.9% of load should be changed to read within 0.8 or 0.9% of peak load based on the BA's choice. Also, see page 7 of the Procedure document and compare to page 1 of Attachment A.

Organization	Yes or No	Question 4 Comment
		The formulae abbreviations for the variables in the Procedure are not likewise abbreviated in Attachment A. For example, "Credit for LR" on Attachment A is "CLR" in the Procedure, but it requires cross checking each document to figure this out. Or CBr in Attachment A, Table 1 is represented as DFCBR in the Procedure, Page 7. Since the same variables are being described, these should be represented the same way in both documents throughout. 2. Similarly, is "IFRO" in Table 1 of Attachment A the same as "FROInt" of the equation that follows on page 2? The same abbreviation should be used to represent this variable. The documents should be revised in general along these lines for all terms. 3. In Procedure document, page 5, paragraph 3 it should read "Table 2", not "1". 4. In the Procedure, it would be good to show Table 1 and Table 2 as Table 1 of Attachment A (i.e. use table lines and borders). 5. At least in the first usage, ERO in the Procedure document should be spelled out as "Electric Reliability Organization (ERO)". 6. In Table 1 of Attachment A, the two footnotes preceded by asterisks (single and double on page 2) should be connected to the table by adding a single superscripted asterisk to the Eastern UFLS value of 59.5, and a double superscripted asterisk to the ERCOT LR value of 1,400.

Response:

(1) The drafting team does not believe any BAs were favored over other BAs. However the drafting team is unclear as to your expressed concerns related to FRCC. In direct communications with FRCC they concluded that the IFRO starting frequency of the prevalent 59.5 Hz for the Eastern Interconnection is acceptable in that it imposes no greater risk of UFLS operation in FRCC for an external resource loss event than for an internal FRCC event.
The drafting team does not agree with the recommended wording change for the bias setting because it would essentially remove the Interconnection minimum FBS. The drafting team does not agree that we are mixing terms between the Procedure and Attachment A. The drafting team uses CBR and DFCBR in both documents defining two different variables. The drafting team clarified CLR.

Organization	Yes or No	Question 4 Comment
(2) The drafting team clarified IFRO/FRO in the documents. **(3) Thank you. The drafting team has corrected this in the document.** **(4) The drafting team thanks you for your comment. However, the majority of the industry does not support your suggested modification. Therefore, the drafting team will leave the tables as shown.** **(5) The drafting team changed ERO to Electric Reliability Organization as per your suggestion.** **(6) Thank you. The drafting team has made the changes.**		
NREL Transmission and Grid Integration Group	Yes	Table 1: CB_r units should be unitless, CB'adj should be Hz.
Response: Thank you for the comment. The drafting team has made these changes.		
NV Energy	Yes	This document is improved, and satisfactorily addresses comments from the prior posting.
Response: Thank you for the comment.		
New York Independent System Operator	Yes	With a new process we are concerned that the interconnection minimum will initially move from 1.0% to 0.9%.
Response: Thank you for your comment. The new process moves the minimum from 1.0% to 0.9%.

pacificorp	Yes	
California Independent System Operator	Yes	

Organization	Yes or No	Question 4 Comment
Energy Mark, Inc.	Yes	
Tacoma Power	Yes	
Southern Company	Yes	
Idaho Power Company	Yes	
Tucson Electric Power	Yes	
Keen Resources Asia Ltd.	Yes	
MISO	Yes	
Puget Sound Energy		In reviewing the Consideration of Comments document, it is clear that the standard drafting team does not wish for the administrative elements of Attachment A to become items addressed during compliance evaluations ("There is no intent to require filing on a certain date and to have the BA prove to the auditor that a filing was made on that date." This quote appears at several places in the Consideration of Comments documents, but first at page 113). However, because Attachment A is referenced in the standard, its provisions, including the timing table, are all mandatory and enforceable. This result is emphasized by the language of requirement R1, which states that entities "...shall achieve an annual Frequency Response Measure (FRM) as calculated and reported in accordance with Attachment A...." This language means that a failure to file a document on a date specified in the attachment would be a potential compliance violation. Because Attachment A is mandatory and enforceable, the standard drafting team should carefully review its provisions and clarify which elements are requirements and which elements are background statements or guidance. In addition, the use of additional headings and section numbers would add in clarifying the document (for example, at the top of page 3, there is a discussion of how an FRSG would calculate its FRM; however, there is an entire section beginning on

Organization	Yes or No	Question 4 Comment
		page 4 addressing FRM where that discussion should instead appear).
Response: The requirement stated in the standard is the only requirement related to FRM. Attachment A is there to provide uniformity in the calculation of the FRM. The drafting team conscientiously included only reliability objectives in the requirements and put procedural steps in the attachment and procedure.		

5. The SDT has moved a portion of the material located in Attachment A and all of the material located in "Attachment B- Process for Adjusting Bias Setting Floor" into a new document "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard". The SDT created this document to assign tasks to the ERO and provide instructions for the ERO to follow when carrying them out under the BAL-003-1 standard. Do you agree that the ERO should perform these tasks and that this document provides sufficient detail for the ERO to do it under the BAL-003-1 standard? If not, what needs to be added to the document?".

Summary Consideration: Several commenters requested clarity on how modifications to the Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard would be made. The drafting team explained that the "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" was not incorporated into the BAL-003 Frequency Response Reliability Standard. As such, modifications to the Procedure will not be developed through the standard development process. Consistent with NERC's commitment to an open and transparent process, the procedure for modifying the event selection process for supporting the Frequency Response Standard is set forth in the opening paragraph of the Procedure for ERO Support of Frequency Response and Frequency Bias Setting document. NERC will post suggested modifications for a 45-day formal comment period, respond to all comments and will discuss the revision request in a public meeting. Revisions will be provided to the NERC BOT for approval and in addition, any modifications will be filed with FERC for informational purposes. This process provides the industry assurance that changes will be properly vetted and that there is an opportunity for stakeholder input.

A couple of commenters questioned how events would be excluded, specifically with regards to during ramping periods. The drafting team stated that all events are considered. Events that occur over known ramping periods are selected last. As an example, the event reflected in the right graph shown in the Procedure would be selected over the event reflected in the graph on the left. If an inadequate number of events are available for that season, then these events may be used. The benefit of using the median of at least 20 events in a year helps minimize the impact of outliers.

A few commenters did not understand why the frequency criteria are different for each Interconnection. The drafting team explained that the frequency criteria was different for each interconnection because the frequency used to measure frequency response is interconnection dependent and varies differently for each interconnection. Larger interconnections have greater frequency response and as a consequence smaller frequency deviations for events of the size typically experienced.

One or two commenters questioned whether certain events should always be included in the evaluation process. The drafting team stated that based on event evaluation by this drafting team, it has been determined that it is impossible to require certain events to be included. This is the reason that the drafting team has developed the Event Selection Criteria.

Organization	Yes or No	Question 5 Comment
Keen Resources Asia Ltd.	No	As a professionally trained published statistical expert never compensated by any balloting participant, I consider event selection criterion 7 to be unacceptable because it violates the fundamental statistical procedure of sampling statistical data "as is" and not pre-selecting the data (to fit some preferred even-distribution over time) and therefore biasing it before applying any statistical procedure to the data. Event criterion 6 is also unacceptable for being an an "ad hoc" explicit exclusion, from the definition of the frequency response being measured, of response to frequency events that occur during a specific kind of scheduled generation and load changes. Said exclusion needs to be written into the definition of the Frequency Response that is being measured. It is procedurally improper and unacceptable to bias the sampling procedure by explicit exclusion of data as an alternative to redefining the thing being sampled. In that case it's not generic Frequency Response that is being sampled, but some specific Frequency-Response-less-Response-to-Excluded-Events that is being measured. It is non-transparent and subterfuge to avoid instead accordingy reworking/narrowing the definition of Frequency Response, especially as said reworking requires a clear technical justification that is absent from this standard, and modifying the existing NERC Glossary definition of Frequency Response which Criterion 6 therefore stands in flat violation of.

Response: Criterion 7 is included in the Event Selection Criteria because the drafting team considers it very important to be able to select and finalize events for analysis quarterly so that the BAs can evaluate their performance as the measurement year unfolds. This necessarily requires minimal criteria to insure that this selection and finalization process can be completed quarterly. The drafting team recognizes that this finalization may have some effect on the sampling, but values the quarterly selection and finalization more than the pure statistical sampling theory. This is a trade-off that the drafting team has chosen to make. Once several years of a regular disparity between seasons of the year were established in terms of number of events in a season, the industry could propose modifying the Standard at that time to adjust Criterion 7 accordingly.

Criterion 6 is included because historic data indicate that the periods within 5 minutes of the top of the hour have shown to have

Organization	Yes or No	Question 5 Comment
higher frequency variability than other periods in the hour. Statistical analysis presented in the FRI Report indicates that pre-disturbance frequency is a significant contributor to the variability of frequency response. The drafting team has chosen to allow the exclusion of events close to the top of the hour when other acceptable events are available until analysis is done of whether these periods have a statistically different frequency response and therefore introduce bias. Meanwhile, as Balancing Authorities are moving toward quarter-hourly scheduling, the higher top-of-the-hour frequency variability prompting the need and application of Criterion 6 is expected to disappear. Therefore, while your recommended alternative of changing the NERC definition of Frequency Response may be statistically correct, from a practical perspective it would likely prove to be a needless chore and to yield a needlessly complicated definition only to have to be changed back again.		
Southern Company	No	Attachment A states that Form 1 is posted annually. The ERO support document selects events annually. The timing for the two documents needs to be aligned so that the set of selected events does not change from quarter to quarter. (If three events are selected for the first quarter those same events will be a sub-set of the 20 events selected for the annual compliance calculations.)
Response: Attachment A indicates that Form 1 with the events from the previous quarter is posted on May 10th, August 10th, November 10th and the second business day in February. It is the intent of the standard that events once posted will be included in the FRM analysis.		
BC Hydro	No	BC Hydro agrees in principle that the ERO should perform these tasks related to BAL-003-1 but has the following concerns: 1. There is no clear indication whether the Interconnection FRO will be calculated every year, and if yes, how each of the factors involved will be determined. 2. It is not clear whether data gathered in these procedures are only for the determination of annual FRO and FBS, or also to determine whether the BA or the FRSG was in compliance to BAL-003-1 for the assessed year. Since the ERO in this Document seems to be the NERC Resources Subcommittee and its Frequency Work Group, we think this fact should be made clear. The Background document should also be reviewed to ensure its alignment in this regard.

Organization	Yes or No	Question 5 Comment
Response: The drafting team has chosen to use the methods presented in the FRI Report to determine the values presented in Table 1 of Attachment A to determine the Interconnection FRO. If the method of calculation by the ERO or the base starting values used to determine the IFRO change (i.e. Resource Contingency Criteria or Prevailing UFLS First Step), then those changes will be subject to the standards process to accept those changes. If the statistical determinates used in the method change (i.e. Starting Frequency, CC_{ADJ}, CB_R, BC'_{ADJ}, and Credit for LR) or the data used to allocate the IFRO among the BAs (i.e. FERC Form 714 data) changes, the new values will be implemented without being subject to the standards process. **The data gathered for the FRO calculation is not compliance related. The calculation of FBS is also not compliance related. However, assuming the information is entered into FRS Form 1 correctly then the FBS number will be used by an auditor to determine compliance with Requirement R2.** **The drafting team has been instructed by NERC to refer to all NERC entities (i.e. Frequency Working Group, Resources Subcommittee, etc) as the ERO.**		
Bonneville Power Administration	No	BPA does not agree with the methodologies outlined in Attachment B. Please see BPA's response to question 6 as well as BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf
Response: Please refer to our response to your comment for Question #6 and our responses to your comments dated 12/8/11.		
Kansas City Power & Light	No	Criteria 3 - Why are frequency thresholds different between regions when generator governor reaction is supposed to be the same between regions? Criteria 5 - What is the reasoning that multiple events that are not stabilized within 18 seconds not being considered? Criteria 6 - How are "changes in scheduled interchange" or load change determined in regions with interconnections with multiple BAs with different time zones?
Response: The frequency criteria is different for each interconnection because the frequency used to measure frequency response is interconnection dependent and varies differently for each interconnection. Larger interconnections have greater frequency response and as a consequence smaller frequency deviations for events of the size typically experienced.		

Organization	Yes or No	Question 5 Comment
The standardized method used to measure frequency response will not work correctly for events that have not stabilized within 18 seconds. **This determination will be made by the ERO (presently the Frequency Working Group).** **All events are considered. Events that occur over known ramping periods are selected last. As an example, the event reflected in the right graph shown in the Procedure would be selected over the event reflected in the graph on the left. If an inadequate number of events are available for that season, then these events may be used. The benefit of using the median of at least 20 events in a year helps minimize the impact of outliers.**		
Duke Energy	No	Duke Energy agrees with allowing the ERO to perform this function, however the industry needs some assurance that this Procedure cannot be changed outside of the Standards Process for approval by the industry. In the sixth line of the third paragraph on page 5, the statement should reference Table 2. Page 5 reads as if the BAs will submit their data based upon Form 1 which includes an adjustment to the Interconnection peak load (initially 0.9), and then the ERO will determine whether the Interconnection minimum FBS is still more than 20% above the measured response - if so, the minimum FBS will be adjusted, requiring the BAs to reassess their new minimum FBS based upon a different factor, and decide whether to use that value or choose a value up to 125% of their FRM, resulting in another iteration of values being submitted to the ERO. If the ERO is going to do an independent assessment of Interconnection Frequency Response to the events, on an annual basis prior to gathering data from the BAs, the ERO could compare the total FBS being used by the BAs against the estimated Frequency Response over that period to determine if an adjustment is warranted, and then the ERO could include the appropriate adjustment factor (0.9, 0.8, etc..) in Form 1 for the BAs to use. If the ERO is not going to estimate the Frequency Response aside from the BAs, multiple iterations will be likely. Duke Energy suggests the following language to cover the point above: “On an annual basis, the ERO will review the Interconnection total minimum Frequency Bias Setting for the prior period and compare it against the Interconnection’s total natural Frequency Response determined for that period. If an Interconnection’s total minimum Frequency Bias Setting exceeds (in absolute value) the Interconnection’s total natural

Organization	Yes or No	Question 5 Comment
		Frequency Response by more (in absolute value) than 0.2 percentage points of the Interconnection non-coincident peak load (expressed in MW/0.1Hz), the minimum Frequency Bias Setting for BAs within that Interconnection may be reduced (in absolute value) based on the technical evaluation and consultation with the regions affected by 0.1 percentage point of Interconnection non-coincident peak load (expressed in MW/0.1Hz) to better match that Frequency Bias Setting and natural Frequency Response. The ERO will include the adjustment factor in the Interconnection Form 1 used by the Balancing Authorities for the calculation of the new minimum Frequency Bias Setting. The Form 1 information from the Balancing Authorities will be gathered by the ERO in coordination with the regions of each Interconnection to determine the final Interconnection Frequency Bias Setting for the next period."
Response: The "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" is not incorporated into the BAL-003 Frequency Response Reliability Standard. As such, modifications to the Procedure will not be developed through the standard development process. Consistent with NERC's commitment to an open and transparent process, the procedure for modifying the event selection process for supporting the Frequency Response Standard is set forth in the opening paragraph of the Procedure for ERO Support of Frequency Response and Frequency Bias Setting document. NERC will post suggested modifications for a 45-day formal comment period, respond to all comments and will discuss the revision request in a public meeting. Revisions will be provided to the NERC BOT for approval and in addition, any modifications will be filed with FERC for informational purposes. This process provides the industry assurance that changes will be properly vetted and that there is an opportunity for stakeholder input. **The reference has been changed from Table 1 to Table 2. Thank you for your comment.** **The review of the information provided by the BAs discussed in the Procedure document will take a significant amount of time. Therefore, the change to the Interconnection Minimum Frequency Bias Setting will occur on the subsequent year's Form 1. This will eliminate the risk of multiple iterations and allow sufficient time for the ERO to consult with the regions as indicated in the Procedure. The drafting team has included clarifying language in the document.**		
Tucson Electric Power	No	I think it should be more clear or better defined that an interconnection does have some input into what events are selected.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. Each interconnection has a representative on the Frequency Working Group that performs the selection of events.		
Exelon Corporation and its affiliates	No	Please see response to question 8.
Response: Thank you for your comment. Please see response to Question 8.		
PJM Interconnection, LLC	No	The Procedure indicates that events that occur when 'large interchange schedule ramping or load change is happening' and 'events occurring within 5 minutes of the top of the hour' should be excluded from consideration. Since interchange schedule ramping and load change occurs at the BA level, this BA believes that the Procedure allows for the selection of events that occur when a BA is experiencing these conditions but Attachment A does not allow for exemption of these events. Also, the Procedure specifies that events that occur at the top of the hour be excluded, if other qualifying events exist, but this does not take into consideration energy markets that allow for sub-hourly schedule changes (e.g. 15 minutes) and the BA is not permitted to exempt these events on Form 1 subjecting the BA to undue compliance risks.
Response: Thank you for your comment. All events are considered. Events that occur over known ramping periods are selected last. As an example, the event reflected in the right graph shown in the Procedure would be selected over the event reflected in the graph on the left. If an inadequate number of events are available for that season, then these events may be used. The benefit of using the median of at least 20 events in a year helps minimize the impact of outliers.		
Texas Reliability Entity	Yes	1. Event Selection Criteria Item 2: Should certain events require mandatory inclusion for FRM calculation (i.e. DCS events)? 2. Event Selection Criteria Item 6: We disagree with the way this is worded. If a unit trips during this time, as it often can, measured frequency response needs to occur. We understand that the results are impacted by the grid condition and perhaps that is why the SDT decided to exclude the issue. Need to define what is intended by a "large"

Organization	Yes or No	Question 5 Comment
		interchange ramp schedule or load change. May also want to consider changing the language from "will be excluded from consideration" to "MAY be excluded from consideration".
Response: Thank you for your comment. Based on event evaluation by this drafting team, it has been determined that it is impossible to require certain events to be included. This is the reason that the drafting team has developed the Event Selection Criteria. **The drafting team wrote the criteria to allow flexibility for any change that significantly impacts frequency.** **The drafting team looked at the language and determined that the present language provides greater clarity. The "will be excluded" is followed by "…if other acceptable frequency excursion events from the same quarter are available." Therefore, it is not a mandatory exclusion.**		
Edison Electric Institute	Yes	EEI supports the ERO's role as defined in the procedure but is concerned that the procedure, unlike approved NERC standards, is unbounded by the current rules for developing standards. For that reason, EEI recommends that the procedure become more formalized and integrated into the standard as an addendum thereby avoiding any Industry concerns that future modification might occur outside the approved processes
Response: Thank you for your comment. The "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" is not incorporated into the BAL-003 Frequency Response Reliability Standard. As such, modifications to the Procedure will not be developed through the standard development process. Consistent with NERC's commitment to an open and transparent process, the procedure for modifying the event selection process for supporting the Frequency Response Standard is set forth in the opening paragraph of the Procedure for ERO Support of Frequency Response and Frequency Bias Setting document. NERC will post suggested modifications for a 45-day formal comment period, respond to all comments and will discuss the revision request in a public meeting. Revisions will be provided to the NERC BOT for approval and in addition, any modifications will be filed with FERC for informational purposes. This process provides the industry assurance that changes will be properly vetted and that there is an opportunity for stakeholder input.		
ACES Power Marketing	Yes	Overall, we agree. However, we suggest the document clarify that the ERO shall

Organization	Yes or No	Question 5 Comment
Standards Collaborators		perform these tasks in coordination with the Resources Subcommittee. It consists of industry experts that can be an extra resource to NERC. Furthermore, NERC staff working with the Resources Subcommittee will provide additional transparency to the process.
Response: Thank you for your comment. The drafting team has been instructed by NERC to refer to all NERC entities (i.e. Frequency Working Group, Resources Subcommittee, etc) as the ERO.		
MISO	Yes	The first hyperlink on page 3 of the Procedure for ERO Support does not work.
Response: Thank you for your comment. The drafting team has corrected this.		
Xcel Energy	YES	It is not clear however, as to if this is actually part of the standard or if it is a document that can be revised without going through the standards development process. Also, the formatting of the doucment should be modified to clearly identify where 'steps/actions' are needed from repsonsible parties, whether that be the ERO or BA/FRSG.
Response: Thank you for your comment. The "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" is not incorporated into the BAL-003 Frequency Response Reliability Standard. As such, modifications to the Procedure will not be developed through the standard development process. Consistent with NERC's commitment to an open and transparent process, the procedure for modifying the event selection process for supporting the Frequency Response Standard is set forth in the opening paragraph of the Procedure for ERO Support of Frequency Response and Frequency Bias Setting document. NERC will post suggested modifications for a 45-day formal comment period, respond to all comments and will discuss the revision request in a public meeting. Revisions will be provided to the NERC BOT for approval and in addition, any modifications will be filed with FERC for informational purposes. This process provides the industry assurance that changes will be properly vetted and that there is an opportunity for stakeholder input.

6. The SDT is now using the method detailed in the Frequency Response Initiative Report dated September 30, 2012 to calculate the Interconnection Frequency Response Obligation. Do you agree that this method provides for the proper amount of Frequency Response? If not, what specifically needs to be changed?

Summary Consideration: Many of the commenters requested clarification on how changes to the methodology defined in Attachment A could be modified. The drafting team explained that Attachment A was part of the standard and as such is subject to the NERC standards process for making any changes.

Several commenters questioned the use of the largest event in the last 10 years for the Eastern Interconnection. The drafting team stated that the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason the SDT has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. If the largest event in the last 10 years falls below 4500 MW then the SDT believes that an N-2 event would be utilized.

One commenter wanted a method to discount outliers. The drafting team explained that this was one of the reasons that they had chosen the median as the appropriate measure for FRM. The benefit of using the median of at least 20 events per year helps to minimize the impact of outliers.

Organization	Yes or No	Question 6 Comment
Bonneville Power Administration	No	BPA does not have specific changes to the methodology to suggest, however, a methodology that arrives at a negative 840 MW per tenth Hz for WECC is obviously under-calculating the frequency bias obligation. Currently WECC has an interconnection bias of over 2000 MW / 0.1Hz and with this bias the frequency is steady state following point B on the frequency response curve. BPA would expect to see frequency decline after point B if the FBO is lowered by almost 60%. BPA also must reiterate that there is still a problem with the method used for modifying the FBO and frequency bias for Balancing Authorities. A high-performing Balancing Authority will have its frequency bias increased each year due to higher response during the events chosen by the ERO. Conversely, a low-performing Balancing Authority will have its frequency bias reduced each year due to lower response during the events chosen by

Organization	Yes or No	Question 6 Comment
		the ERO.
Response: After review of comments, the drafting team feels confident with the current method of calculating Frequency Response Obligation as outlined in the Frequency Response Initiative report. This standard requires minimum bias setting not to be less than 0.9% of the non-coincidental peak load for a multi-BA interconnection. This will ensure that minimum bias settings will be based on Interconnection's non-coincidental peak load rather than biased toward low-performer. The minimum Frequency Bias settings requirement are outlined in Table 2 of "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" **The drafting team points out that there is not a Frequency Bias obligation and that the currently measured response for the Western Interconnection is approximately -1200 MW/0.1 Hz. This number is above, but much closer to the required level of -840 MW/0.1 Hz under this standard.**		
Tucson Electric Power	No	I believe that the frequency bias obligation of the Western Interconnection is understated.
Response: The drafting team points out that there is not a Frequency Bias obligation and that the currently measured response for the Western Interconnection is approximately -1200 MW/0.1 Hz. This number is above, but much closer to the required level of -840 MW/0.1 Hz under this standard.		
Duke Energy	No	Similar to our earlier concern, the industry needs some assurance that the calculation of the Interconnection FRO described in the report cannot be changed outside of the Standards Process for approval by the industry. Duke Energy does not support using a 4500 MW loss as the basis for determining the FRO for the Eastern Interconnection for future events. However, as the calculation also includes 59.5 Hz as the basis for determining the FRO, the result is an allocation which can be supported. To the extent that the standard drafting team moves in the direction of using 59.7 Hz as the basis for the FRO, then it needs to follow a methodology similar to the other Interconnections for determining the credible multiple contingency to cover.
Response: Thank you for your comment. The Attachment A is part of the standard and as such is subject to the NERC standards		

Organization	Yes or No	Question 6 Comment
process manual for making any changes. **The drafting team agrees with your concern regarding the use of 4500 MW. However, the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason the SDT has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. If the largest event in the last 10 years falls below 4500 MW then the SDT believes that an N-2 event would be utilized.**		
New York Independent System Operator	No	The drafting team should consider some method for discounting outliers, that may not be explainable.
Response: Thank you for your comment. All events are considered. Events that occur over known ramping periods are selected last. As an example, the event reflected in the right graph shown in the Procedure would be selected over the event reflected in the graph on the left. If an inadequate number of events are available for that season, then these events may be used. The benefit of using the median of at least 20 events in a year helps minimize the impact of outliers.		
Southern Company	No	The industry needs some assurance that the calculation of the Interconnection FRO described in the report cannot be changed outside of the Standards Process for approval by the industry. We do not support using a 4500 MW loss as the basis for determining the FRO for the Eastern Interconnection for future events. However, as the calculation also includes 59.5 Hz as the basis for determining the FRO, the result is an allocation which can be supported. To the extent that the standard drafting team moves in the direction of using 59.7 Hz as the basis for the FRO, then it needs to follow a methodology similar to the other Interconnections for determining the credible multiple contingency to cover.

increased reliability margin for the Eastern Interconnection. If the largest event in the last 10 years falls below 4500 MW then the SDT believes that an N-2 event would be utilized.		
PPL NERC Registered Affiliates	No	The PPL Affiliates support the comments of the SERC OC Standards Review Group on this question
Response: The Attachment A is part of the standard and as such is subject to the NERC standards process for making any changes. **The drafting team agrees with your concern regarding the use of 4500 MW. However, the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason, the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. If the largest event in the last 10 years falls below 4500 MW then the SDT believes that an N-2 event would be utilized.**		
Keen Resources Asia Ltd.	No	This question is falsely worded. The SDT is specifically NOT using the method detailed in the Frequency Response Initiative Report dated September 30, 2012. So the term "this method" is practically meaningless in this question because it is not clear if it means "the SDT's method" or "the FRI's method". The Background Document specifically states on page 29: "The NERC Frequency Response Initiative Report addressed the relative merits of using the median versus linear regression for aggregating single event frequency response samples into a frequency response measurement score for compliance evaluation. This report provided 11 evaluation criteria as a basis for recommending the use of linear regression instead of the median for the frequency response measurement aggregation technique. The FRSDT made its own assessment on the basis of these evaluation criteria on September 20, 2012, but concluded that the median would be the best aggregation technique to use initially when the relative importance of each criterion was considered." What needs to be changed, besides properly wording this question? The FRI method of linear regression should be adopted, and the SDT method of median should be rejected, in the standard to change the first sentence of this question into a true statement from a false statement and to, in answer to the question, provide for the proper amount of

Organization	Yes or No	Question 6 Comment
		Frequency Response.
Response: Thank you for your comments. The drafting team disagrees that the methodology for calculating the IFRO used in this standard is different than that detailed in the FRI Report. The drafting team considered replacing median with linear regression but chose to use the median because of its better resiliency to data quality problems found in the Actual Net Interchange data used in the frequency-response calculation.		
SERC OC Standards Review Group	No	We believe the industry needs some assurance that the calculation of the interconnection FRO cannot be changed without rigorous review and input from the industry. In addition the clarification should be made how the one in ten year loss for the Eastern Interconnection (4500 MW) would change after 10 years. Would the same methodology be used or would the largest Category C (n-2) be used?
Response: Thank you for your comment. The Attachment A is part of the standard and as such is subject to the NERC standards process manual for making any changes. **The drafting team agrees with your concern regarding the use of 4500 MW. However, the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. If the largest event in the last 10 years falls below 4500 MW then the SDT believes that an N-2 event would be utilized.**		
Arizona Public Service Company	NO	1. The Frequency Response initiative report should be added to the standard as an appendix. It is not clear where to find this report. 2. The jusitification for dividing delta frequency with C to B ratio is not adequate and not clear.
Response: Thank you for your comment. 1) The drafting team disagrees that the FRI Report should be attached to this standard as an appendix. We do agree that it should be easier to locate. **2) Please refer to the FRI Report for the reasoning you request.**		
Edison Electric Institute	Yes	EEI finds the method to be acceptable but as mentioned in our response to question

Organization	Yes or No	Question 6 Comment
		No. 5 (above), we believe that the procedure should be more formally documented as an addendum. Such a change would ensure that the document would remain unchanged outside of the approved standards making process. Additionally, EEI does not support using 4500 MW loss as the basis for determining the FRO for the Eastern Interconnection for future events. However, as the calculation also includes 59.5 Hz as the basis for determining the FRO, the results is an allocation which we believe is acceptable. In the future, should the SDT decide to use 59.7 Hz as the basis for the FRO, than it will need to follow a methodology similar to the other interconnections for determining the credible multiple contingency to cover.
Response: Thank you for your comment. The Attachment A is part of the standard and as such is subject to the NERC standards process manual for making any changes. **The drafting team agrees with your concern regarding the use of 4500 MW. However, the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. 7. Based on Industry comments received the SDT made significant clarifying modifications to the Background Document. Do you agree that this document provides sufficient information to justify the rationale used by the SDT in developing the draft standard and provides the industry with sufficient understanding of the issues being addressed by the standard?

Summary Consideration: Several of the commenters questioned why the formula for FRO was missing. The drafting team explained that this was a problem incurred during the conversion to a pdf file. Once the problem was recognized by NERC, it was immediately fixed during the posting.

A couple of commenters felt that there should be discussion in the Background Document concerning "inertial response". The drafting team stated that they saw a limited role for inertial response in the context of this standard. The standard inherently does not address inertial requirements. It is of interest herein because of its role in determining the post-contingency rate of decline of frequency, as it ultimately impacts the duration of time before the frequency nadir (point C) occurs. The drafting team considered a more elaborate description of inertial response, but believes that it is tangential to the main mission of this standard.

A few of the commenters questioned the use of the largest event in the last 10 years as the criteria for the Eastern Interconnection. The drafting team explained that the results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details are provided on pages 52 through 55 of the Frequency Response Initiative paper.

Organization	Yes or No	Question 7 Comment
ACES Power Marketing Standards Collaborators	No	(1) The formula for calculating Frequency Response Obligation appears to be missing on page 23. (2) We are confused by the varying sample rates for the different scan rates in the Definitions of Frequency Values for Frequency Response Calculation table on page 13. It would appear that the time range of values for the average B value varies more than necessary by scan rate. For example, for 2-second scan rates, sampling would start at 20 seconds and end at 52 seconds. However, for the 4-second scan rates, sampling

Organization	Yes or No	Question 7 Comment
		starts at 24 seconds and ends at 48 seconds. Why would it not also cover 20 and 52 seconds for a 4-second scan rate?
Response: Thank you for your comment. (1) This was corrected during the posting. The formula was lost when converting to a pdf file. **(2) The SDT has corrected the table.**		
Bonneville Power Administration	No	BPA continues to fundamentally disagree with the approach that BAL-003-1 is developing into. Please reference BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf.
Response: Thank you for your comment. Please refer to our response to your comments dated 12/8/11.		
Keen Resources Asia Ltd.	No	See reply to Question 6. Also, the Background Document is seriously deficient in the discussion of inertial response and therefore how imbalances "cause" frequency deviation. The Background Document is overflowing in discussion of how frequency deviation causes frequency response. In other words, the Background Document is "reactive" and not "proactive". The Background Document lacks any discussion of the internal dynamics of rotating machines, beginning with any definition of what Inertial Response is. Inertial Response is the instantaneous power produced by the lag ("inertia") in the ability of the generator's rotor to slow down to the frequency of the magnetic field in the generator's fixed stator whose frequency is instantaneously lowered by a change in phase angle between voltage and current that is due to a sudden loss of interconnected generation to meet load. Adjustments by voltage response within milliseconds and near the location of the loss are sometimes possible to avert rapid spread of a loss to the frequency of the entire interconnection, and constitute the ongoing work of the Phasor Project long ago initiated by the DOE in the persistent absence of NERC interest or work in this area. NERC and drafting team members under advisement by NERC staff studiously resisted so much as any mention of frequency deviation causation in discussions or in the Background Document. An

Organization	Yes or No	Question 7 Comment
		inexplicable technical Cold War and Berlin Wall built in the 1970s and today separating the DOE Phasor Project from NERC Frequency Response standard development and NERC's so-called Frequency Response "Initiative" needs to be ended and torn down. My document http://www.robertblohm.com/Inertia.doc provides missing technical support and explanation for graphs 1-7 on pages 4-10 of the Background Document, on the basis of an exact understanding of Inertial Response.
Response: Thank you for your comment. The drafting team sees a limited role for inertial response in the context of this standard. The standard inherently does not address inertial requirements. It is of interest herein because of its role in determining the post-contingency rate of decline of frequency, as it ultimately impacts the duration of time before the frequency nadir (point C) occurs. The drafting team considered a more elaborate description of inertial response, but believes that it is tangential to the main mission of this standard.		
Northeast Power Coordinating Council	No	While the discussion of primary frequency response includes inertial energy, the term inertial energy is missing from the definition of “primary frequency response”.
Response: Thank you for your comment. The drafting team sees a limited role for inertial response in the context of this standard. The standard inherently does not address inertial requirements. It is of interest herein because of its role in determining the post-contingency rate of decline of frequency, as it ultimately impacts the duration of time before the frequency nadir (point C) occurs. The drafting team considered a more elaborate description of inertial response, but believes that it is tangential to the main mission of this standard.		
Consolidated Edison Co. of NY, Inc.	No	While the discussion of primary frequency response includes inertial energy, the term inertial energy is missing from the definition of “primary frequency response”.
Response: Thank you for your comment. The drafting team sees a limited role for inertial response in the context of this standard. The standard inherently does not address inertial requirements. Organization	Yes or No	Question 7 Comment
PPL NERC Registered Affiliates	Yes	The PPL Affiliates applaud the SDT for developing this technical justification document.
Response: Thank you for your comment.		
Duke Energy	Yes	Though Duke Energy does not agree with some of the points in the Background Document, it does justify the rationale used by the SDT. Additional comments: at the top of page 23, it states that the basic Frequency Response Obligation is based on non-coincident peak load and generation data reported in FERC Form 714, however the actual calculation is missing and should be based upon the reported MWh, not the peak load as stated. At the bottom of page 23, it states that Attachment A proposes the three options for event criteria, however doesn't clarify why it was chosen that the Eastern Interconnection would be held to the largest event over the last 10 years, while others will be based upon the largest category C loss-of-resource (N-2) event.
Response: Thank you for your comment. (1) This was corrected during the posting. The formula was lost when converting to a pdf file. **(2) The results for the current Eastern Interconnection model do not represent observed response adequately. The models for the other Interconnections have a better match. For this reason the drafting team has recommended the largest event in the last ten years be used to provide for an increased reliability margin for the Eastern Interconnection. Further details are provided on pages 52 through 55 of the Frequency Response Initiative paper.**		
SERC OC Standards Review Group	Yes	We agree with the Duke Energy comments on this question.
Response: Thank you for your comment. (1) This was corrected during the posting. The formula was lost when converting to a pdf file. **(2) The results for the current Eastern Interconnection model do not represent observed response adequately. 8. If you are not in support of this draft standard, what modifications do you believe need to be made in order for you to support the standard? Please list the issues and your proposed solution to the issue.

Summary Consideration: A couple of commenters expressed concern with the fact that the onus for Frequency Response was being put on the BAs who do not own or operate the generators. The drafting team explained that they had heard some of the same concerns, but there are quite a few good reasons why this standard is a good starting point to meet the FERC directives in Order No. 693 (which NERC was given a specific date next year to deliver).

There are several other standards where a similar situation occurs. As you note, many BAs don't own generators. Still, they are responsible for meeting DCS and CPS. The BAs control regulating and contingency reserves to meet the standards. Similarly a TOP is responsible for maintaining voltage even though they may own no capacitor banks or generators to control VArs.

To measure frequency response fairly accurately (one of the 693 directives), you have to monitor the BAs' frequency response (or generator governor response if the standard was generator centric) to about 30 events per year. There are about 140 BAs in North America. There are on the order of 4000 generators that would have to report under a generator-centric standard. How do you verify performance of 120,000 observations annually?

The standard is a backstop standard beyond which we could expect problems during light load conditions for a large contingency. It is not intended to be difficult to meet. As proposed, the standard has a performance obligation about half of what we see today in actual operation. The obligation for the East is on the order of -1000MW/0.1Hz. We have about -2200MW/0.1Hz on average. The standard allows the formation of frequency response sharing groups (similar in concept to DCS' RSGs) and allows obtaining response from other BAs contractually. This means there should be no BAs out of compliance once the standard is in place.

A couple of commenters stated that they thought the standard was confusing. The drafting team stated that they appreciated their concern that the standard is confusing, but the drafting team believed that the proposed standard is as clear as possible while covering all of the issues involved and that based on comments received the industry was not in agreement.

One or two commenters requested clarity on how modifications to the Attachment A could be made and if the FRS Forms 1 and 2 had to be used. The drafting team explained that Attachment A was part of the standard and would have to use the Standard Development Process to make any modifications. The drafting team also stated that the FRS Forms were required to be used in the reporting.

A couple of commenters questioned the use of the Background Document. The drafting team explained that the Background Document was only intended to be used for education and training similar to other training references in the NERC Operating Manual.

Organization	Yes or No	Question 8 Comment
ACES Power Marketing Standards Collaborators	No	(1) We believe that the drafting team work has demonstrated that the standard is unnecessary. The data presented in the posting shows that all of the interconnections easily exceed the required Frequency Response necessary to avoid actuating UFLS relays. Since one of the main purposes of the standard is to provide sufficient Frequency Response, it would seem the purpose is already met without implementing and enforceable standard. So why is a standard needed to compel required Frequency Response if it is already provided? (2) Even though we believe the supporting data for the posting demonstrates the standard is unnecessary, we understand NERC is required by a FERC directive to provide a standard. Given this requirement, we do believe the drafting team has largely provided a reasonable standard and supporting documents that only require a few additional adjustments (see our comments in other questions for these adjustments) to finalize the standard. As a result, we will likely end up supporting the standard once these final adjustments are made.
Response: Thank you for your comment. We agree that the standard meets the primary directive to provide Frequency Response. This standard will set a backstop to assure that Frequency Response will not decline past a "point of no return" **For issues raised in other questions please refer to our response to those questions.**		
Independent Electricity	No	a. We do not support R2 as drafted, specifically the phrase "until directed to change by the ERO". We do not agree that the ERO has any authority to "direct" a BA or FRSG, or

Organization	Yes or No	Question 8 Comment
System Operator		any responsible entities, to make changes to the Frequency Bias Setting or take any operating or operations planning actions. We suggest to replace the word “directed” with “requested”. b. In R2, the words “subject to” can be interpreted differently. We suggest to replace them with “in accordance with” to parallel the intent as conveyed in R1. c. We are still concerned with the status of Attachment A, as indicated in our comments submitted under Q4 - that it is unclear if the materials in Attachment A must be adhered to or not. A standard should not have an attachment whose enforcement status is unclear as part of a requirement. d. FRS Forms 1 and 2 are referenced in Attachment 1, which itself has an unclear status on measurability and enforceability. It is also unclear if FRS Forms 1 and 2 must be used to submit the requested data. Collectively, Attachment 1, FRS Form 1 and Form 2 make the standard very confusing as to which parts must be complied with. Much better clarity is needed to clearly convey the standard ‘s requirements that are measurable, enforceable and must be complied with.
Response: Thank you for your comments, **a) The drafting team believes that the term “direct” is less ambiguous. The drafting team believes that using the term “request” could leave the impression that the action is optional.** **b) The drafting team has adopted your suggested language.** **c) Please refer to the drafting team response to Question #4.** **d) The Attachment is mentioned in the standard requirements and is therefore enforceable. Since the FRS Forms are discussed in the Attachment then they must be used in the calculation process.**		
Bonneville Power Administration	No	BPA continues to fundamentally disagree with the approach that BAL-003-1 is developing into. Please reference BPA’s extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found at: http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf.

Organization	Yes or No	Question 8 Comment
Response: Thank you for your comment. Please refer to the drafting team response to your comments submitted on 12/8/11.		
Exelon Corporation and its affiliates	No	Exelon checked "no" because it does not support the current draft standard. Exelon's position is that efforts to modify frequency monitoring and control should be directed at the existing standards. Since Frequency Bias is already a component of ACE, and ACE performance is tracked by both CPS 1 and CPS 2, it seems evident that NERC already has in place mechanisms for evaluating frequency response. NERC already has in place mechanisms for ensuring sustained frequency response during a contingency, through the Disturbance Control Standard (DCS) and its requirement for the contingent Balancing Authority to deploy resources. Under the current BAL-003-0.1b language, Balancing Authorities are given a consistent means for determining frequency bias, via the minimum requirement of 1% peak generation or 1% peak load. Together with the above references to existing CPS 1 performance measurements, current standards meet the objectives outlined in BAL-003-1. This proposed draft BAL-003-1 complicates the setting of Frequency Bias and attempts to go beyond that purpose into frequency response performance, without clear rules for how to perform. Exelon is also concerned with moving this standard forward while there is an ongoing field trial that could impact whether this standard should be put into place. For example, waivers are in place for CPS 2 for participating Balancing Authorities and there is ongoing effort with the BAAL field trial set of standards that will establish performance metrics around frequency control. As an alternate approach to waiting to move forward on the standard, Exelon recommends the following BAL-003-1 Requirement language: R1. The ERO shall identify up to five [5] system frequency events in each Interconnection that will be included in the Form 1 and 2 data requests for Balancing Authorities by April 30th each year. R2. Each Balancing Authority shall submit the following data to the ERO annually by July 15: R2.1 The total annual net output of generating plants inside the Balancing

Organization	Yes or No	Question 8 Comment
		Authority Area. R2.2 The total annual load with losses inside the Balancing Authority Area. R3. Each Balancing Authority shall calculate its Frequency Response Measure using Forms 1 and 2 as posted by the ERO. (See Attachment A_Form 1 and Form 2) R4. Each Balancing Authority or Frequency Response Sharing Group shall submit Forms 1 and 2 to contacts designated by the ERO before the expiration of ERO established deadlines, which shall be no earlier than 30 days after posting of Forms 1 and 2. R5. The ERO shall post the following information: R5.1. Each Interconnection's Frequency Response Obligation R5.2 Each Balancing Authorities Frequency Response Obligation R5.3 Each Balancing Authorities Frequency Bias Setting R6. Each Balancing Authority shall implement in its ACE equation its ERO established Frequency Bias Setting during the ERO established three-day implementation period. No further adjustments can be implemented outside of the parameters established below in the upcoming year unless a Balancing Authority coordinates with the Regional Entity and the affected Balancing Authorities. R6.1 A Balancing Authority using a fixed Frequency Bias Setting sets its Frequency Bias Setting to the greater of (in absolute value): R6.1.1. The number the BA chooses between 100% and 125% of its Frequency Response Measure as calculated on FRS Form 1. R6.1.2. The Balancing Authorities share of the Interconnection Minimum as determined by the ERO. R6.2 A Balancing Authority using a variable Frequency Bias Setting shall maintain a setting that is:

Organization	Yes or No	Question 8 Comment
		R6.2.1 Less than zero at all times, and R6.2.2 Equal to or greater in magnitude than its Frequency Response Obligations when Frequency varies from 60 Hz by more than +/-0.036 Hz. R7. Each Frequency Response Sharing Group or Balancing Authority that is not a member of a FRSG shall monitor its Frequency Response Obligation and work with generating facilities or demand response resources to provide sufficient Frequency Response to meet the Frequency Response Obligation assigned by the ERO. R8. Each Balancing Authority that adds or removes generation or load, including through the use of dynamic transfers, shall notify the ERO to ensure that any needed adjustments to the Interconnection Frequency Response Obligation or Balancing Authority Frequency Response Obligation and Bias can be calculated. R8.1. The ERO shall notify all affected Balancing Authorities of modifications to the Frequency Response Obligation due to the addition or removal of generation or load. R9. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent of the sum of the Frequency Bias Setting as communicated by the ERO for the participating Balancing Authorities.
Response: Thank you for your comment. ACE, CPS1, CPS2, BAAL and DCS are all standards that measure Secondary Control actions. The inclusion of the Frequency Bias Setting in ACE and these standards make them blind to Primary Frequency Control and thus incapable of helping with the evaluation of Frequency Response (Primary Frequency Control). R1 sets clear rules with respect to how much Frequency Response is required from each BA through the Frequency Response Obligation (FRO) and Frequency Response Measure (FRM). The BAAL Field Trial is investigating issues associated with Secondary Frequency Control only and is not impacted by and has no impact on Primary Frequency Control and BAL-003. The drafting team has considered the suggestions contained in the requirements suggested and has explained in the Background document the reasons for writing the		

Organization	Yes or No	Question 8 Comment
requirements and measures as contained in the draft BAL-003-1.		
Duke Energy	No	Given the FERC deadline approaching for NERC to deliver a Frequency Response standard, Duke Energy supports the adoption of this standard with some reservations. We believe that the proposed standard addresses the FERC directive to NERC, however it also introduces some longer-term issues related to secondary control and related costs that may have not been anticipated by the FERC. To that point, Duke Energy believes that if this standard is adopted, the industry will have the time and opportunity through the NERC standards development process to mitigate some of the concerns presented in our comments."
Response: Thank you for your affirmative response and clarifying comment. The drafting team agrees that there could be some impact on other standards but the implementation period will allow for time to adjust and learn		
Tucson Electric Power	No	I feel that a BA's frequency bias for the upcoming year should not be related to present performance. A BA may have a good response one year and not good response another year and therefore the threshold keeps moving around. I feel it should be related to BA size and therefore somewhat standardized. E.g. a high-performing Balancing Authority will have its frequency bias increased each year due to higher response during the events chosen by the ERO. Conversely, a low-performing Balancing Authority will have its frequency bias reduced each year due to lower response during the events chosen by the ERO.
Response: Thank you for your comment. The drafting team believes that control and frequency performance improve if the Bias Setting and the BA's Frequency Response are as closely matched as possible. Low performing BAs will still have to provide the Interconnection minimum Bias Setting. In an unlikely case where a high performing BA has an internal change that markedly reduces their Frequency Response, there are provisions in the standard's supporting document to accommodate an intra-year change in its Bias Setting.		
New York Independent System Operator	No	In general we support the work of the DT, and the proposal to measure the systems response to frequency events, along with the method to determine the FRO. My

Organization	Yes or No	Question 8 Comment
		outstanding concern is with enforcement on an entity that does not own the resources that provides the frequency response or the lack of obligation for the entity with the information to provide to the BA to make the assessment of expected frequency response. BA's should at a minimum be given assurance that resources will provide data that BA's could use to forecast frequency response and take corrective actions.

Response: Thank you for your comment. We've heard some of the same concerns, but there are quite a few good reasons why this standard is a good starting point to meet the FERC directives in Order No. 693 (which NERC was given a specific date next year to deliver).

There are several other standards where a similar situation occurs. As you note, many BAs don't own generators. Still, they are responsible for meeting DCS and CPS. The BAs control regulating and contingency reserves to meet the standards. Similarly a TOP is responsible for maintaining voltage even though they may own no capacitor banks or generators to control VArs.

To measure frequency response fairly accurately (one of the 693 directives), you have to monitor the BAs' frequency response (or generator governor response if the standard was generator centric) to about 30 events per year. There are about 140 BAs in North America. There are on the order of 4000 generators that would have to report under a generator-centric standard. How do you verify performance of 120,000 observations annually?

MISO has done analysis to find all large frequency events over the past year and how the generators in its footprint performed. It turns out that many of the generators aren't on line for any of the events and only a few of the generators were on line for all large events. So what do you do with generators that are not frequently run? Even if a generator ran 50% of the time, you wouldn't have enough events to do a quality measure in a year.

The standard is a backstop standard beyond which we could expect problems during light load conditions for a large contingency. It is not intended to be difficult to meet. As proposed, the standard has a performance obligation about half of what we see today in actual operation. The obligation for the East is on the order of -1000MW/0.1Hz. We have about -2200MW/0.1Hz on average. The standard allows the formation of frequency response sharing groups (similar in concept to DCS' RSGs) and allows obtaining response from other BAs contractually. This means there should be no BAs out of compliance once the standard is in place.

Finally, to make it a generator standard precluded other solutions (load management, flywheels, market solution, etc.).

Organization	Yes or No	Question 8 Comment
Tri-State Generation and Transmission Assn., Inc.	No	It is our opinion that there has not been enough justification to merit creating a new standard. If additional justification is provided then frequency responsive reserves should be a subset of spinning reserves much like spinning reserves are a subset of operating reserves.
Response: Thank you for your comment. This standard will set a backstop to assure that Frequency Response will not decline past a "point of no return" **This standard does not prescribe a method to provide Frequency Response but does provide for measuring that Frequency Response is delivered.** **Spinning reserve is outside the scope of the industry approved SAR.**		
Puget Sound Energy	No	See comment in response to question 4 above for a discussion of Attachment A concerns. Appendix 1 of the Frequency Response Standard Background Document contains a discussion about why the use of net actual interchange to calculate an entity's Frequency Response Measure might introduce inaccuracies into that calculation. That discussion ends with the following statement: "The frequency response is buried within the typical hour to hour operational cacophony superimposed on actual net interchange values. The choice of metrics will be important to artfully extract frequency response from the noise and other unrepresentative error." Based on these statements, it is very difficult to support the standard's approach to calculating the Frequency Response Measure.At Puget Sound Energy (PSE), though, we believe that there is another factor to add to the "operational cacophony" listed in Appendix 1. PSE is a comparatively small BA with limited internal generation. We are embedded between two of the largest energy exporters in the Western Interconnection and, when there is a frequency event, their response flows through PSE's system. As a result, PSE will experience transmission losses associated with the two BAs' frequency response as it flows through our system. When PSE's frequency response is measured using net actual interchange, these losses obscure, at least in part, our system's

Organization	Yes or No	Question 8 Comment
		frequency response. As a result, we ask the standard drafting team to consider specifying a process that would allow us to propose and use an equivalent measure of frequency response. For example, while we understand the concerns and difficulties associated with measuring frequency response at the generator as the default measure for all BAs, in our case, a choice to use that measurement option might prove to be a more-feasible way to comply with the standard.
Response: Thank you for your comment. Please refer to our response to your comments on Question #4. **Analysis of Field trial data has not shown that this has been a problem.** **The spreadsheets have been designed to allow for adjustment for dynamically scheduled resources located in another BA.**		
PJM Interconnection, LLC	No	See previous comments. Also, this standard should be applicable to GOP's as well as BA's with, at a minimum, the following requirements added: Each GOP shall follow all directives of it's Balancing Authority pertaining to frequency responsive operation, including but not limited to the status, droop & deadband settings of their governors. Each GOP shall provide to their BA the status and droop & deadband settings of their governors, and headroom available to respond to frequency deviations, as requested.
Response: Thank you for your comment. MISO has done analysis to find all large frequency events over the past year and how the generators in its footprint performed. It turns out that many of the generators aren't on line for any of the events and only a few of the generators were on line for all large events. So what do you do with generators that are not frequently run? Even if a generator ran 50% of the time, you wouldn't have enough events to do a quality measure in a year. **Generator verification standards (MOD 27) are scheduled to be revised. The drafting team believes that this will address your second concern**		
PPL NERC Registered	No	The PPL Affiliates are concerned that the document referred to "Attachment A" is

Organization	Yes or No	Question 8 Comment
Affiliates		directly referenced in the proposed standard's requirements but not actually attached to the standard itself as Attachment A. Therefore, it is not clear how the proposed document could be modified in the future. Having such material incorporated into a standard takes away from the open and transparent stakeholder drive process.
Response: Thank you for your comment. The attachment is mentioned in the requirement within the standard and therefore becomes a part of the standard. Any modifications needing to be made to the attachment will have to use the Standards Process.		
Consolidated Edison Co. of NY, Inc.	No	The purpose of BAL-003 was to calculate frequency bias in the ACE equation used in BAL-001. The Standard is currently confusing to understand and it is unclear how the bias is calculated. It is recommended that efforts should be made to clarify the changes, especially Attachment A.
Response: Thank you for your comment. The drafting team appreciates your concern that the standard is confusing, but the drafting team believes that the proposed standard is as clear as possible while covering all of the issues involved. **The drafting team will either develop training materials to provide better understanding for both the FRM and FBS calculations or recommend to the NERC Resources Subcommittee to develop said materials.**		
Northeast Power Coordinating Council	No	The purpose of BAL-003 was to calculate frequency bias in the ACE equation used in BAL-001. The Standard is currently confusing to understand, and it is unclear how the bias is calculated. It is recommended that efforts should be made to clarify the changes, especially in Attachment A.
Response: Thank you for your comment. The drafting team appreciates your concern that the standard is confusing, but the drafting team believes that the proposed standard is as clear as possible while covering all of the issues involved. **The drafting team will either develop training materials to provide better understanding for both the FRM and FBS calculations or recommend to the NERC Resources Subcommittee to develop said materials.**		
Kansas City Power & Light	No	The Standard does not consider instances for smaller BAs that operate generation for peak conditions and acquire energy for most of the operating year.

Organization	Yes or No	Question 8 Comment
Response: Thank you for your comment. The drafting team is unsure of your precise question. However, if your question concerns meeting your performance obligation year around, then the process does allow for mechanisms for a BA to obtain Frequency Response from external resources		
NV Energy	No	While I support the concept of a Frequency Response Standard with minimum performance obligations, this Standard places the entire obligation for performance on the Balancing Authority (and Frequency Reserve Sharing Group). Requirements R2-R4 are properly assigned to the BA, as this is the entity that is responsible for the configuration and parameters in the ACE equation, including the provision of a frequency bias setting. Requirement 1, however, is a performance requirement over which the BA in the Functional Model has virtually no control or ability to influence. Only a Generator Owner or Generator Operator is in a position of control over the performance under this requirement through the operational control and configuration of the responding generating units. In most BA's, the host BA entity also owns a fair amount, even a vast majority in many cases, of the generation within the BA. However, even in the event that the host BA owned 100% of the generation within its metered boundary, it is the action of the entity exercising its GO/GOP function that impacts the frequency response performance within the Balancing Area. Assignment of R1 to the BA is inappropriate from the standpoint that reliability requirements are to be assigned to the Reliability Functions who are capable of causing compliance to occur. A BA has limited ability to influence the outcome of the R1 performance metric. This is unlike other BA-assigned requirements, such as those related to DCS or CPS compliance. For those, the BA does have considerable influence regarding the curtailment of transactions to restore ACE, the direction of plant loading so as to distribute operating reserve, etc. In contrast, performance under this proposed R1 of BAL-003-1 is dependent upon the actions of the GO/GOP in such things as governor settings, generator control system configuration and other operatinal or maintenance activities conducted at the generating plant site. For this reason, it is inappropriate to assign this performance requirement to the BA. Rather, the requirements should be allocated among the GO/GOP's of the on-line generation in some fashion.In further support of

Organization	Yes or No	Question 8 Comment
		this notion, refer to the NERC Functional Model, where it is provided that one of the tasks for Generator Operation is to support Interconnection frequency.
Response: **Thank you for your comment. We've heard some of the same concerns, but there are quite a few good reasons why this standard is a good starting point to meet the FERC directives in Order No. 693 (which NERC was given a specific date next year to deliver).** **There are several other standards where a similar situation occurs. AESO		1. The AESO disagrees with using a non-authoritative background document that has definitions/description of terms used in the reliability standard. It is the opinion of the AESO that these definitions/descriptions need to be authoritative. 2. The AESO has previously submitted comments to the SDT that for the purpose of the FRM calculation, BAs should be able to exclude or include events based on specific conditions or consideration, such as data quality or event suitability (e.g. BA separation from the Interconnection). The revisions made by the SDT do not enable the inclusion of other relevant events in the FRM calcualtion by a BA. The AESO would like to to see these type of events to be permitted in the FRM calculation by a BA.
Response: Thank you for your comment. 1) The Background Document is intended for education and training similar to the other training references in the NERC Operating Manual. **The drafting team believes that any new definitions that are located in the standard will ultimately be placed in the NERC glossary.** **2) The drafting team believes that your concern will be addressed through the process since:** **a) separation events would not be selected,** **b) the median will exclude the outlier situations, and** **c) If the data is corrupted, the FRS Forms allows for exclusion of that event.**		
Public Service Enterprise Group		PSEG entities will vote “Negative” on the standard until this Project 2007-12 achieves the following: 1. It coordinates with Project 2010-14.1 Phase 1 of Balancing Authority Reliability-

Organization	Yes or No	Question 8 Comment
		based Controls Reserves, specifically BAL-012-1, regarding (a) definitions and (b) requirements that address frequency response in both standards. a. Definitions that need to be coordinated: BAL-003-2 - "Frequency Response Obligation" and BAL-012-1 - "Frequency Responsive Reserve." b. Requirements that need to be coordinated: i. BAL-003-1, per R1, states "Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation." ii. BAL-012 requires BAs to have sufficient Frequency Responsive Reserves per R6, which requires BAs to "assess, on at least an hourly basis, that it has sufficient Regulating Reserve, Contingency Reserve, and Frequency Responsive Reserve to meet its reserve plan(s) to ensure reliable operation of the Bulk Electric System." For Frequency Responsive Reserves, R3 in BAL-012-1 requires BAs to develop an annual plan for these reserves.BAs should not be subject to duplicative requirements for frequency response requirements in different standards that are underdevelopment. Only one standard needs to define the frequency response requirements for BAs (we suggest that be BAL-003-1), although other standards, such as BAL-012-1, may reference that obligation. However, this decision should be made by consensus between the two SDTs. 2. It coordinates with Project 2010-14.1 Phase 1 of Balancing Authority Reliability-

Organization	Yes or No	Question 8 Comment
		based Controls Reserves, specifically BAL-012-1, to develop an application guide that would be attached to one of the standards and that could be referenced by each standard. The application guide would include: a. A hypothetical implementation plan for a BA that demonstrates how the BA may meet its Frequency Response Obligation or Frequency Responsive Reserve prior to an event. This is a technical issue and should not be confused with the institutional issue in #3 below. b. An explanation of the relationship between Regulating Reserve, Contingency Reserve, and Frequency Responsive Reserve contained in BAL-012-1 so that potential double counting (and whether that is proper of improper), is addressed. 3. Project 2007-12's "Frequency Response Standard Background Document" dated October, 2012 lists several methods of obtaining Frequency Response. Most of those are extracted below. We have provided questions and commentary that we ask the team to address. a. "Regulation services." This is addressed in BAL-001-0.1a. The purpose of this standard is "To maintain Interconnection STEADY-STATE FREQUENCY within defined limits by balancing real power demand and supply in real-time. How is this related to Frequency Response for a disturbance? (The team may answer this as part of 2.b above.) b. "Through a tariff (e.g. Frequency Response and regulation service). " The team is advised to review the actual pro-forma OATT schedule for Schedule 3 "Regulation and Frequency Response Service" which is specifically limited to services providers that are "capable of providing this service as necessary to follow the moment-by-moment changes in load." Again, how is this related to Frequency Response for a disturbance? (The team may answer this as part of 2.b above.) c. "From generators through an interconnection agreement." The FERC's pro-

Organization	Yes or No	Question 8 Comment
		forma Standard Large Generator Interconnection Agreement (LGIA) per Order 2003 contains no requirement for generators to provide Frequency Response service, and we are not aware on ANY interconnection agreement that does. We ask that the team point to ANY interconnection agreement with such a requirement. Modification of an interconnection agreement to incorporate such a requirement would require the consent of both parties. d. "Contract with an internal resource or loads."Since Frequency Response service would likely be considered as a necessary service to provide Transmission Service under an OATT, it would require a tariff. What existing tariff applies in the U.S.?The "methods" above that the team has listed have the factual errors described. The standard BAL-003-1 cannot be implemented until the necessary tariffs are developed that permit BAs and FRSGs to contract for Frequency Response services. Once that is done, BAL-003-1 can dictate the performance requirements of a BA or FRSG. o For context, FERC OATT schedules relevant to Frequency Response DO NOT set performance requirements. Schedule 3 (Regulation and Frequency Response Service) sets forth a tariff for the service, while BAL-001-0.1a sets forth performance requirements in aggregate for a BA or RSG. Likewise, Schedule 5 (Operating Reserve - Spinning Reserve Service) and Schedule 6 (Operating Reserve - Supplemental Reserve Service) set tariffs for both services, while BAL-002-1 sets performance requirement. Without an OATT schedule for Frequency Response service, BAs and FRSGs will have no means to contract with generators or loads to provide Frequency Response per BAL-003-1. The team should address this concern.
Response: Thank you for your comment. There is significant coordination between the two drafting teams and this coordination will continue as all standards referenced are posted for comment. **With regard to double jeopardy, both drafting teams have been coordinating to ensure this does not occur.** **We believe it is important from a reliability perspective to have a performance based standard. The ultimate need for tariff changes, interconnection agree, etc will be based on a BA's need to meet the standard.**		

Organization	Yes or No	Question 8 Comment
Within the measures for R1 and the discussions in the Background document, the drafting team believes that FERC and the industry will be able to develop the changes to tariffs to address your concerns with the BA contracting with sources of Frequency Response to meet its FRO. The BA is also responsible for dispatch levels of resources that provide Frequency Response. Now that Frequency Response has been clearly defined and is able to be measured, sources of Frequency Response for delivery of the service can be developed by the industry. **Once both BAL-003-1 and BAL-012-1 have passed, the drafting team believes it would then be an appropriate time for the members of the two drafting teams to develop an application guide.**		
American Electric Power		There is no leverage for the BA to require the generator to carry their burden of addressing governor settings or droop settings, yet the BA is obligated to meet some performance measures in that regard.This revision adds new performance measure responsibilities on the BA who likely has no direct control over every resource affecting their performance within their footprint. We are not necessarily challenging the performance measures themselves, nor their underlying objectives, however AEP views this as a gap in responsibilities which potentially effects reliability. AEP suggests that GOPs be considered as part of this standard so that their performance can be factored into the process to meet the performance objectives.
Response: Thank you for your comments. We've heard some of the same concerns, but there are quite a few good reasons why this standard is a good starting point to meet the FERC directives in Order No. 693 (which NERC was given a specific date next year to deliver). **There are several other standards where a similar situation occurs. As you note, many BAs don't own generators. Still, they are responsible for meeting DCS and CPS. The BAs control regulating and contingency reserves to meet the standards. There are about 140 BAs in North America. There are on the order of 4000 generators that would have to report under a generator-centric standard. How do you verify performance of 120,000 observations annually?**		

Organization	Yes or No	Question 8 Comment
MISO has done analysis to find all large frequency events over the past year and how the generators in its footprint performed. It turns out that many of the generators aren't on line for any of the events and only a few of the generators were on line for all large events. So what do you do with generators that are not frequently run? Even if a generator ran 50% of the time, you wouldn't have enough events to do a quality measure in a year. The standard is a backstop standard beyond which we could expect problems during light load conditions for a large contingency. It is not intended to be difficult to meet. As proposed, the standard has a performance obligation about half of what we see today in actual operation. The obligation for the East is on the order of -1000MW/0.1Hz. We have about -2200MW/0.1Hz on average. The standard allows the formation of frequency response sharing groups (similar in concept to DCS' RSGs) and allows obtaining response from other BAs contractually. This means there should be no BAs out of compliance once the standard is in place. Finally, to make it a generator standard precluded other solutions (load management, flywheels, market solution, etc.).		
SPP Standards REview Group		We support the standard as proposed.
Response: The drafting team thanks you for your support.		

9. Please provide any other comments (that you have not already provided in response to the questions above) that you have on the draft standard BAL-003-1.

Summary Consideration: A couple of commenter disagreed with the VSLs for Requirement R1. The drafting team explained that the VSLs were a starting point for the enforcement process. The combination of the VSL and VRF is intended to measure a violation's impact on reliability and thus levy an appropriate sanction. Frequency Response is an interconnection-wide resource. The proposed VSLs are intended to put multi-BA Interconnections on the same plain as single-BA Interconnections. Consider a small BA that whose performance is 70% of it's FRO. If all other BAs in the Interconnection are compliant, the small BA's performance has negligible impact on reliability, yet would be sanctioned at the same level as a BA who was responsible for its entire Interconnection. It is not rational to sanction this BA the same as a single BA Interconnection that had insufficient Frequency Response. To do otherwise would treat multi-BA Interconnections tens of times more harshly than single BA Interconnections. However, the drafting team has added language to the requirement to reference the Interconnection Frequency Response Obligation.

One commenter felt that there was an inconsistency between Requirement R4 and Requirement R1 and Attachment A concerning how a BA providing Overlap Regulation Services would calculate its FBS. The drafting team disagreed with their comment. Under the two options in R4 the BAs must still comply with the minimum setting requirements through the calculations performed under R2. In your example, if both BAs turned in FRS Form 1 showing a FBS based on the 100% - 125% minimum these two numbers would be added together for compliance with R4.

One commenter felt that the definition should state that it is a negative value. The drafting team explained that while the desired value would be negative it is mathematically feasible for the actual value to be positive but that value would by definition mean that the entity failed the measurement for Requirement R1.

One commenter disagreed with putting the onus on the BA for providing Frequency Response. The drafting team The drafting team explained that they had heard some of the same concerns, but there are quite a few good reasons why this standard is a good starting point to meet the FERC directives in Order No. 693 (which NERC was given a specific date next year to deliver).

There are several other standards where a similar situation occurs. As you note, many BAs don't own generators. Still, they are responsible for meeting DCS and CPS. The BAs control regulating and contingency reserves to meet the standards. Similarly a TOP is responsible for maintaining voltage even though they may own no capacitor banks or generators to control VArs.

To measure frequency response fairly accurately (one of the 693 directives), you have to monitor the BAs' frequency response (or generator governor response if the standard was generator centric) to about 30 events per year. There are about 140 BAs in North America. There are on the order of 4000 generators that would have to report under a generator-centric standard. How do you verify performance of 120,000 observations annually?

The standard is a backstop standard beyond which we could expect problems during light load conditions for a large contingency. It is not intended to be difficult to meet. As proposed, the standard has a performance obligation about half of what we see today in actual operation. The obligation for the East is on the order of -1000MW/0.1Hz. We have about -2200MW/0.1Hz on average. The standard allows the formation of frequency response sharing groups (similar in concept to DCS' RSGs) and allows obtaining response from other BAs contractually. This means there should be no BAs out of compliance once the standard is in place.

One commenter questioned how the event selection process would work. The drafting team stated that the event selection process was outline in the Procedure for ERO Support of the Frequency Response and Frequency Bias Setting Standard.

Organization	Question 9 Comment
ACES Power Marketing Standards Collaborators	(1) Please strike “that is a member of a multiple BA Interconnection” in R2 and R3. The language makes the requirements difficult to read. We understand this is trying to clarify that these requirements should not apply to BAs such as ERCOT since changing its Frequency Bias Setting does not need to be coordinated with other BAs among other issues, and we do not have an issue with this intent. However, there is an easier way to address this issue without creating a confusing requirement. The SDT should include seeking a variance for the ERCOT area in conjunction with developing the standard. (2) Please strike “in order to represent the Frequency Bias Setting for the combined Balancing Authority Area” in Requirement R4 as it is superfluous and incorrect. First, the two bullets provide the necessary information making the statement unnecessary. Second, the BA Areas are not combined into a single BA Area as implied with the statement “combined Balancing Authority Area”. They are still in fact two distinct BA Areas.

Organization	Question 9 Comment
	(3) The data retention period for R1, R2, R3, and R4 is not consistent with the NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C - Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention section states that data shall be kept for the current calendar year plus the three previous calendar years. This could be up to four years which exceeds the BA audit period of three years. It is unnecessary for a BA to maintain evidence that was already verified in a prior audit. We recommend changing the evidence retention period to three years. (4) Has the drafting team coordinated the addition of the Frequency Response Sharing Group (FRSG) with the Functional Model Working Group and the NERC staff responsible for organizational registration? If not, please do so as NERC will need to be willing to register entities as a FRSG if it is to be utilized. Furthermore, the Functional Model Working Group should document the purpose and intent of the FRSG .(5) We disagree with the VSLs for R1. The VSLs are structured such that a BA's or FRSG's violation is dependent upon the rest of the interconnection to determine the severity level of the violation. If the BAs collectively fail to achieve the Interconnection Frequency Response obligation, a 2% violation of the Frequency Response Measure jumps from a Lower VSL to a High VSL. This should never be the case. No violation by a registered entity should become potentially more or less severe based on the violation of another entity. We encourage the drafting team to work with NERC Legal department in reviewing this VSL further as FERC has already allowed ISO/RTO violations investigation to draw in third parties that potentially contributed to the ISO/RTO violation to ensure the appropriate party is fined. The principal is similar here in ensuring the appropriate BA is fined for its violation not the violations/failures of other BAs. The background document mentions on page 31 that the motivation for structuring the VSL in this manner was to prevent BAs in multiple BA interconnections from being sanctioned disproportionately. We appreciate the draftingteam considering this issue but believe there is a simpler solution. Four VSLs could simply be written based on the percentage the BA misses its own Frequency Response Obligation. Furthermore, the compliance enforcement process already considers if the violation impacted reliability when assessing a sanction

Organization	Question 9 Comment
	.(6) The Frequency Response Obligation (FRO) term is used inconsistently with the definition in the VSLs for R1. The first part of each BA implies that the Interconnection has an FRO. However, the definition specifically states that FRO is the BA's "share of the required Frequency Response". It does not apply to the Interconnection. How can the Interconnection have a share of the required frequency response? A new term may need to be defined for the Interconnection. (7) The implementation plan still references Requirement R5. There is no such requirement .(8) Requirement R1 is not consistent with the recent direction NERC has taken to refocus on reliability and looking forward during compliance audits rather than backwards. For instance, NERC has proposed monitoring internal controls of registered entities because this will provide a reasonable assurance that the registered entity is prepared to comply in the future. Current compliance audits focus mostly on past performance and provide no indication of future reliability. How does Requirement R1 support this forward looking vision when it is a lagging indicator that looks at historical performance? (9) Requirement R4 appears to be inconsistent with Requirement R1 and Attachment A. On page 3, Attachment A states the BA shall set its Frequency Bias Setting to 100% to 125% of it Frequency Response Measure or Interconnection Minimum. However, Requirement R4 states that the BA providing Overlap Regulation Service shall set its Frequency Bias Setting to the sum of its Frequency Bias Settings on FRS Form 1 and FRS Form 2 of its own BA and the BA to which its provides Overlap Regulation Service. For simplicity let's call the BA providing Overlap Regulation Service BA X and the BA receiving the service BA Y. Why would the BA X not set its Frequency Bias Setting to 100% to 125% of the sum of BA X's and BA Y's Frequency Response Measure? This would make Requirement R4 parallel with R2. (10) We do not understand the difference between the two bullets in Requirement R4. They appear to say essentially the same thing and the background document provides no discussion to distinguish their differences. Please provide further explanation.
Response: Thank you for your comments. **(1) The proposed variance alternative could create unnecessary work for different organizations.** **(2) The proposed elimination of words could help but, the elimination could bring more questions than benefits.**	

Organization	Question 9 Comment
(3) The drafting team believes that the language proposed in the draft standard is typical of other standards and is not in violation of anything. (4) The drafting team is coordinating as you stated. (5) VSLs are a starting point for the enforcement process. The combination of the VSL and VRF is intended to measure a violation's impact on reliability and thus levy an appropriate sanction. Frequency Response is an interconnection-wide resource. The proposed VSLs are intended to put multi-BA Interconnections on the same plain as single-BA Interconnections. Consider a small BA that whose performance is 70% of it's FRO. If all other BAs in the Interconnection are compliant, the small BA's performance has negligible impact on reliability, yet would be sanctioned at the same level as a BA who was responsible for its entire Interconnection. It is not rational to sanction this BA the same as a single BA Interconnection that had insufficient Frequency Response. To do otherwise would treat multi-BA Interconnections tens of times more harshly than single BA Interconnections. However, the drafting team has added language to the requirement to reference the Interconnection Frequency Response Obligation. (6) The drafting team has clarified the VSL. (7) The drafting team has corrected the Implementation Plan. (8) The drafting team disagrees. The drafting team believes that this is a performance based standard similar to BAL-001 CPS and BAL-002 DCS requirements. With regards to "internal controls" the drafting team believes that this is an enforcement activity not a standards activity. (9) The drafting team disagrees with your comment. Under the two options in R4 the BAs must still comply with the minimum setting requirements through the calculations performed under R2. In your example, if both BAs turned in FRS Form 1 showing a FBS based on the 100% - 125% minimum these two numbers would be added together for compliance with R4. (10) Under the first bullet, two BAs have submitted two FRS Form 1 document in accordance with R1. Under the second bullet, one entity has turned in a single FRS Form 1 with all information for the two BAs combined.	
Keen Resources Asia Ltd.	A probabilistic/statistical basis needs to be developed for the FRM that assesses for usage of frequency response (causation of frequency error) and not just for provision of it. This would also overcome NERC's singular focus on reaction, and NERC's color-blindness to proaction, pointed out in my reply to question 7.
Response: Thank you for your comment. As part of the ongoing evaluation of Frequency Response this may be considered.	
SPP Standards REview Group	Additional typos:Change the ')' to a '(' in the 4th line of M1 of the standard.No further comment

Organization	Question 9 Comment
Response: Thank you for your comment. This has been corrected.	
Arizona Public Service Company	As mentioned in Item 8 above, the VRF language is too complicated and hard to follow. Even though the VRF poll is non binding, it needs to be clear and simple enough to be understood.
Response: Thank you for your comments. The drafting team is assuming you mean the VSL. VSLs are a starting point for the enforcement process. The combination of the VSL and VRF is intended to measure a violation's impact on reliability and thus levy an appropriate sanction. Frequency Response is an interconnection-wide resource. The proposed VSLs are intended to put multi-BA Interconnections on the same plain as single-BA Interconnections. Consider a small BA that whose performance is 70% of it's FRO. If all other BAs in the Interconnection are compliant, the small BA's performance has negligible impact on reliability, yet would be sanctioned at the same level as a BA who was responsible for its entire Interconnection. It is not rational to sanction this BA the same as a single BA Interconnection that had insufficient Frequency Response. To do otherwise would treat multi-BA Interconnections tens of times more harshly than single BA Interconnections. However, the drafting team has added language to the requirement to reference the Interconnection Frequency Response Obligation.	
BC Hydro	BC Hydro respectfully submits these additional comments/observations: 1.The proposed standard seems to indicate that it is applicable to the identified responsible entities at all times. There might be circumstances where a BA that belongs to a multiple-BA Interconnection became isolated and has to operate in restorative mode which might require adjusting the frequency bias to a value less negative than the minimum FBS setting value in order to follow the much reduced load/generation level in the area. We suggest adding some language in either the Applicability section or in individual Requirements to recognize these circumstances. 2.Effective Dates: the proposed standard specifies a fixed period (12-month or 24-month) following Regulatory Approval which may fall in the middle of the year while the calculation and implementation are performed on an annual basis. Does this represent any conflicts? 3.The proposed standard does not clearly specify whether a BA must chose between using fixed bias or variable bias for the entire year. Should BAs be allowed to switched back and forth between the two methods? If yes, more details may be needed to account for the FRM and minimum FBS. 4.The proposed standard does not clearly specify whether a BA can be part of a FRSG for only part

Organization	Question 9 Comment
	of the year or must be the whole year 5.The definition of FRO, FRM, FBS, etc. should all include language to indicate the "negative" nature of the value. 6.Measure M2 should have "and uses a fixed bias" added for clarity purpose. 7.In the Additional Compliance Information section of the proposed standard the following info still exists: For Interconnections that are also Balancing Authorities, Tie Line Bias control and fFlat Ffrequency control are equivalent and either is acceptable. Since all reference to AGC Modes have been removed from the Requirements, this additional info should also be removed.
Response: Thank you for your comments. **(1) The drafting team does not believe that there is any difference between adherence to the current standard and the proposed standard. With regard to islanded operations, the drafting team believes that other standards prevail under those conditions.** **(2) The timelines are not requirements and may be adjusted to meet the annual calculation process proposed by the standard.** **(3) The drafting team believes the standard as drafted, allows for two types of bias, fixed and variable. A fixed bias is a single number for the entire period. A number that changes within the period is a variable bias and is subject to Requirement R3.** **(4) FRS Form 1 and 2 allows for the transfer of Frequency Response on a per event basis.** **(5) While the desired value of the FRM would be negative it is mathematically feasible for the actual value to be positive but that value would by definition mean that the entity failed the measurement for Requirement R1. The FBS definition states that it is an inverse contribution to the interconnection frequency; therefore the definition does not need to reference a negative value. The FRO will be an allocation of the IFRO whose calculation methodology will provide a negative number. The allocation of a negative number will result in a negative number. For these reasons the SDT did not modify the definitions.** **(6) Requirement R2 is only applicable to entity's using a fixed bias therefore Measure M2 only applies to those utilizing a fixed bias.** **(7) The proposed elimination of words could help but, the elimination could bring up more questions than benefits.**	
Edison Electric Institute	EEI supports the efforts and improvements made by the Standards Drafting Team (SDT) in the latest version of BAL-003 and believe those changes have been responsive to the directives in Order 693. However, we recognizes that the Industry has struggled with this standard and remains split as to how best to respond to those directives and in some cases there are those who question

Organization	Question 9 Comment
	whether a standard is even necessary. Given the many open issues and the concerns expressed by stakeholders we anticipate that this standard will once again fail to achieve sufficient support to gain approval. Should the Standard fail to achieve ballet approval, it is our hope that NERC Staff and the NERC Board of Trustees will allow the SDT a little more time to resolve any final issues that have been identified in this latest ballet. Although we recognize that May 31, 2013 does not leave the ERO with a lot of time to comply with this FERC imposed deadline, we still remain confident that given the progress made by the SDT a standard, which is acceptable to the Industry, is still possible. To the extent EEI can help, we are committed to working with member companies to communicate the issues and exchange insights from the SDT to help as we can to achieve a positive outcome.
Response: Thank you for your comment and support.	
Manitoba Hydro	Purpose: Is the reference to 'Interconnection Frequency' supposed to be 'Frequency Response'? This would be consistent with later wording in the standard. R1: (1) The acronym 'FRO' is used inconsistently within the document. (2) The phrase "to ensure that sufficient Frequency Response ..." should be separated from the requirement as it is (i) not descriptive of the required actions (ii) redundant with the stated purpose at the beginning of the standard. In general, such a drafting technique should be avoided as it may allow Responsible Entities to argue that a violation has not occurred where the specific action that is described has not been taken, but the purpose referenced in the requirement has been met. M1: The reference to 'documented formula' is not clear. Does this imply that the FRSG or BA have a record of their calculation? In addition, there is a typo, a random ')' after FRM. M2: Should include the words 'and uses a fixed Frequency Bias Setting...' after overlap Regulation

Organization	Question 9 Comment
	Service to make the wording consistent within the Requirement. M3: The wording of this measure switches tenses between 'is' and 'was'. For consistency, we suggest that this be corrected. NERC Glossary definition of an FRSG is a group of BAs that collectively maintain, allocate and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members. No mention is made of the agreement including the sharing or delegation of responsibility related to FRM. Accordingly, the standard should only reference a BA being able to delegate responsibility to an FRSG if the RSG Agreement allows for such delegation. Data Retention 1.3. (1) As the standard is currently drafted, both the BA and the FRSG would be required to retain data or evidence to show compliance with requirements R1 and M1. It is unclear whether this is the intention, or whether it would be acceptable that just one or the other would maintain such records .(2) In the third paragraph, it should be clarified who is required to keep information related to non compliance if the BA belongs to an FRSG - the BA or the FRSG or both.

Response: Thank you for your comments. The drafting team believes that the purpose statement is correct as written. The standard is for both Frequency Response and Frequency Bias Setting both of which support Interconnection Frequency.

(1) The drafting team corrected the identified FRO inconsistencies within the documents.
(2) The drafting team was advised by NERC staff to include the language you are referencing.
(3) M1 – Yes the entity must have a record of their calculation. The typo has been fixed.
M2 - Requirement R2 is only applicable to entity's using a fixed bias therefore Measure M2 only applies to those utilizing a fixed bias.
M3 – The drafting team corrected the use of "is" in the last line of the measure.
(4) The drafting team believes that any agreement between members of a RSG is an issue that the RSG would handle. We have a created the FRSG to address the concerns that an existing RSG may or may not be a FRSG.

Organization	Question 9 Comment
Data Retention **(1) Both the BA and FRSG must maintain data. At a minimum the BA needs data to document its bias setting obligation. In addition, the BAs data may be needed to demonstrate FRSG performance.** **(2) The drafting team believes that the language is clear; the entity that is found non-compliant would be the entity that would be required to keep the data.**	
JEA	R1 places the burden for compliance on the BA but the BA does not control generation assets and should not be solely responsible for maintaining frequency response. While the standard can still define the amount of Frequency Response for each BA, there needs to be an obligation on the GO/GOP to provide that service as directed by the BA and they should also be held accountable for compliance. Finally, we do not believe that a sufficient study has been conducted to determine the impact of this standard. We are concerned that a substantial number of compliance issues could result and that the resulting cost to maintain compliance could be excessive and we suggest it be put through the Cost Effective Analysis Process (CEAP). We suggest that the proposed values be evaluated on a sample size within each region to determine the number of compliance issues and for those issues that are found determine what the BA would have to do be compliant.
Response: Thank you for your comments. We've heard some of the same concerns, but there are quite a few good reasons why this standard is a good starting point to meet the FERC directives in Order No. 693 (which NERC was given a specific date next year to deliver). **There are several other standards where a similar situation occurs. As you note, many BAs don't own generators. Still, they are responsible for meeting DCS and CPS. The BAs control regulating and contingency reserves to meet the standards. Similarly a TOP is responsible for maintaining voltage even though they may own no capacitor banks or generators to control VArs.** **To measure frequency response fairly accurately (one of the 693 directives), you have to monitor the BAs' frequency response (or generator governor response if the standard was generator centric) to about 30 events per year. There are about 140 BAs in North America. There are on the order of 4000 generators that would have to report under a generator-centric standard. How do you verify performance of 120,000 observations annually?**	

Organization	Question 9 Comment
MISO has done analysis to find all large frequency events over the past year and how the generators in its footprint performed. It turns out that many of the generators aren't on line for any of the events and only a few of the generators were on line for all large events. So what do you do with generators that are not frequently run? Even if a generator ran 50% of the time, you wouldn't have enough events to do a quality measure in a year. **The standard is a backstop standard beyond which we could expect problems during light load conditions for a large contingency. It is not intended to be difficult to meet. As proposed, the standard has a performance obligation about half of what we see today in actual operation. The obligation for the East is on the order of -1000MW/0.1Hz. We have about -2200MW/0.1Hz on average. The standard allows the formation of frequency response sharing groups (similar in concept to DCS' RSGs) and allows obtaining response from other BAs contractually. This means there should be no BAs out of compliance once the standard is in place.** **Finally, to make it a generator standard precluded other solutions (load management, flywheels, market solution, etc.).** **The SDT does not believe that there is a need to perform a "cost analysis". The numbers are lower than the numbers we are presently seeing.**	
Los Angeles Department of Water and Power	Spinning reserves are intended to support the interconnection response to the loss of a resource. If BAL-003-1 is adopted through this Project, the LADWP recommends that the spinning reserve requirements of BAL-002-0.1b and BAL-STD-002-0 be removed, as the Spinning reserve requirement would require utilities to reserve resources in excess of the reserves required in BAL-003-1. LADWP recognizes that this recommendation may be handled through a separate NERC Project, but wanted to submit this comment to bring light to this potential conflict in Reliability Standards.
Response: Thank you for the observation.	
Tacoma Power	The addition to the Frequency Bias Setting definition of "and discourage response withdrawal through secondary control systems" seems incomplete. Tacoma Power does not see anything in the standard that addresses (or measures) how a frequency bias setting will discourage response withdrawal through secondary systems. This should either be more fully addressed or removed.

Organization	Question 9 Comment
Response: The FRI Report and the Background Documents contain explanations on this issue.	
SERC OC Standards Review Group	The comments expressed herein represent a consensus of the views of the above namedmembers of the SERC OC Standards Review Group only and should not be construed as theposition of SERC Reliability Corporation, its board, or its officers.
Response: Thank you for the clarification	
Duke Energy	The concern raised in Duke Energy's comments in item 4 will not be a factor for a few years, but will be an issue as more and more BAs are in the position of their FRM being better than the Interconnection Minimum allocation. We believe that the language that we proposed for calculating the minimum FBS in a multiple-BA Interconnection allows for the proper incentives for BAs to maintain FRM much better than required, and allows for comparable measurement of secondary control performance between similarly-sized BAs, while presenting no risk to reliability.
Response: Thank you for your comment. The industry will utilize information from the process related to this standard to make future decisions. Also, please refer to our response to your Question #4 comment.	
Puget Sound Energy	The definition of "Frequency Response Obligation" applies only to a Balancing Authority. However, requirement R1 applies to both FRSGs and BAs and includes a Frequency Response Obligation that applies to each of those entities. As a result, the definition must also address an FRSG's Frequency Response Obligation. The acronym for Balancing Authority is not included following the first reference to the term in requirement R1 (looks like an inadvertent deletion). Requirement R1 states that an entity "... shall achieve an annual Frequency Response Measure (FRM)...." However, the definition of Frequency Response Measure already includes the concept of annual. As a result, the word "annual" should be removed from the requirement. Requirement R1 includes the language "... to ensure that sufficient Frequency Response is provided

Organization	Question 9 Comment
	by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation." This language is a purpose statement rather than a requirement applicable to a FRSG or a BA and should be excluded from the requirement. So long as an FRSG or BA achieves the FRM calculated in accordance with Attachment A, it has done everything necessary to comply with the standard. There are discrepancies between the implementation plan and the proposed standard:- The definitions of "Frequency Response Measure" and "Frequency Response Obligation" in the Implementation Plan are different from those proposed in the draft standard.- The Implementation Plan references "Reserve Sharing Group" rather than "Frequency Response Sharing Group".- The Implementation Plan does not include a definition for the term "Frequency Response Sharing Group".- The Implementation Plan continues to reference R5 in the discussion of the standard's proposed effective date. The annual process dates listed on page 32 of the Background document appear to be inconsistent with those listed in Attachment A.
Responses: Thank you for your comments. **The calculation of FRO is done at the individual BA level. Those BAs that are part of a FRSG must sum their individual FROs to determine the FRSG FRO. This is clearly stated in Attachment A.** **The drafting team corrected this oversight.** **The drafting team disagrees that the term "annual" should be removed as it provides greater clarity as written.** **The drafting team was advised by NERC staff to include the language you are referencing.** **The drafting team has corrected the Implementation Plan.** **The dates are not firm dates but are examples for the process.**	
California Independent System Operator	The ISO supports the development of BAL-003-1 and would like to offer the following comments/suggestions: (1) Some BAs may have to develop a new Ancillary Service product to ensure that its FRO can be met and believes that 12 months after FERC's approval may not provide adequate time to

Organization	Question 9 Comment
	stakeholder and modify market software applications. The ISO suggest increasing the implementation timeline by at least one more year. (2) If the implementation timeline cannot be changed, then the ISO suggests that compliance should be waived for the first year of operation under BAL-003-1. (3) Some BAs may elect to procure a portion of its FRO through bilateral agreements for certain hours (e.g. off-peak) with a neighboring BA. Since a contingency could be in a BA other than the two BAs under a bilateral agreement, the standard or background document needs to clarify the duration of frequency response so that transmission reservation is not a requirement for frequency response. The ISO believes that the BA experiencing the contingency should have adequate arrangements in place to deal with internal contingencies.
Response: Thank you for your comments. **(1) The implementation date for Requirement R1 is 24 months after FERC approval, not 12 months. We believe that this would provide ample time.** **(2) See (1) above.** **(3) The measurement period is 20 to 52 seconds after the beginning of the event. Additionally, there is no mention of transmission requirements for purchase or delivery of Frequency Response.**	
Portland General Electric Company	The issue with proposed Reliability Standard BAL-003-1, requirement R1, is that the Annual Frequency Response Measure (FRM) is determined after the fact with an entity unable to identify or monitor compliance (on non-compliance) along the way. Also, the requirement seems to go the opposite direction of NERC's risk based initiatives where collecting historic compliance information become unsustainable.
Response: Thank you for your comments. **(1) The identification and posting of events will occur on a quarterly basis as stated in the Procedure Document. This will allow BAs to monitor their compliance.** **(2) The SDT believes that this is a performance based standard similar to BAL-001 CPS and BAL-002 DCS requirements.**	

Organization	Question 9 Comment
MRO NSRF	The MRO NSRF is concerned with the drafting team's exclusion of single Balancing Authority Interconnections from compliance with Requirement R2. To ensure a consistent approach in the application of BAL-003-1, recommend R2 be revised as follows: R2). Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined subject to Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation ...
Response: Based on the comment rather than the proposed language the drafting team is providing the following response. The drafting team discussed the applicability of bias requirements to single BA Interconnections extensively. The consensus of the FRSDT was that single BA Interconnections inherently have strong incentives to accurately represent their frequency response characteristic. Any adverse consequences of misrepresenting the frequency response characteristic will be borne solely by that BA and cannot affect other BAs in other Interconnections adversely.	
Southern Company	The organization selecting events must ensure that the change in frequency is outside the normal dead-band of generator governors. Many of the events selected in the past have not been outside the dead-band and therefore, the frequency response was much less than expected. Southern Company proposes .07 which is consistant with WECC.
Response: Thank you for your comments. The drafting team has created a Procedure Document that details the event selection criteria for each Interconnection. This should alleviate the concern of smaller events being selected.	
Independent Electricity System Operator	The proposed effective date for this standard conflicts with Ontario regulatory practice respecting the effective date of implementing approved standards. It is suggested that this conflict be removed by appending to each of Section A1.3 and A1.4, after "months after applicable regulatory approval", of the standard to the following effect:", or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities."The same change should be made to the two bullets in the proposed Implementation Plan.
Response: The drafting team appreciates your comment. However, this language is required to be used by the drafting team with	

Organization	Question 9 Comment
the only modification allowed to be the number of months prior to implementation.	
Northeast Power Coordinating Council	The VSL's refer to the FRM (Frequency Response Measure). If that is the intent of the Standard, then GO's and GOP's should be included in the applicability since they are the entities responding to the AGC signals. If the intent is the FRO (Frequency Response Obligation) only, then the VSL's should be updated.
Response: The FRM is not intended to measure response to AGC signals but is intended to measure response to frequency changes. Therefore, the drafting team does not believe that any modification is warranted.	
Consolidated Edison Co. of NY, Inc.	The VSL's refer to the FRM (Frequency Response Measure). If that is the intent of the Standard, then GO's and GOP's should be included in the applicability since they are the entities responding to the AGC signals. If the intent is the FRO (Frequency Response Obligation) only, then the VSL's should be updated.
Response: The FRM is not intended to measure response to AGC signals but is intended to measure response to frequency changes. Therefore, the SDT does not believe that any modification is warranted.	
Tucson Electric Power	This is an important task and the efforts of the drafting team are appreciated.
Response: Thank you for the recognition.	
The United Illuminating Company	UI believes the VRF should be High. The VRF justification for Medium is that the prior year's bias setting would exist in the control system so the impact would not cause a Cascade. UI thinks that is an adjustment factor that is applied after non-compliance is determined. Not having settings is likely to cause cascade so the VRF is High.
Response: The drafting team reviewed the definition for the VRF levels and believes that the appropriate levels were used for each requirement.	
Tri-State Generation and	We are concerned with the tariff implictations associated with this standard. Will this standard

Organization	Question 9 Comment
Transmission Assn., Inc.	create the need for an additional ancillary service under the FERC pro forma OATT?
Response: The drafting team believes that your comment is possible but does not think that it is in the scope of NERC to make changes to the FERC pro forma OATT.	
NREL Transmission and Grid Integration Group	We commend the drafting team for a rigorous approach to this new and important standard. Being observers who have a strong interest in this standard as it applies to much of the research that we do, but not stakeholders of the ultimate standard, we submit our overall comments as recommendations here. We believe there are a few potential issues, that may at least need more thought before going forward. The first is the credit for LR. (1) Overfrequency can be an issue: using ERCOT as an example, with -282 MW/0.1Hz response and 1400 MW of LR all responsive at 59.7 Hz, if just meeting FRO requirements, the 1400MW LR can all be triggered with a loss of (282*3=) 846MW, causing (1400-846=)554MW of overgeneration. This can be exacerbated by further increases of LR without recognition of the triggering frequency, and the disconnect between BA and interconnection in the other interconnections. (2) With crediting LR toward the Interconnection, it will not give incentive toward BAs to provide it. We believe the LR should contribute to the BA FRO rather than discount the IFRO. (3) There is no requirement for frequency response capacity (ie MW) available to provide the FR. This is a nonissue in today's world with the amount of spinning reserve already available, but the issue could be apparent on future systems with increased reserve sharing, or reserve capacity from resources that operate in modes which do not provide frequency response. The European Interconnection requirement has two intentions: a 3,000 MW capacity requirement and a 1,500 MW/0.1Hz FRO requirement that is allocated out to its Transmission System Operators. This could solve the issue with LR and generators, where LR is in MW and generation governing is in MW/0.1Hz. (4) It is likely, and from our understanding is true in some areas like ERCOT, that the LR is selected based on market solutions, and may not be available all times of the year. This is another reason why the LR should contribute to the BA FRO rather than discount the IFRO. (5) It may be beneficial to guide frequency settings for LR or even multiple settings to mimic a

Organization	Question 9 Comment
	droop curve for LR. Other potential issues not related to the LR. We think the SDT has done an outstanding job on reviewing the data sets and determining statistically based values to better account for different factors that may affect minimum frequency levels. We agree that there are current issues in the primary governing response, but that there may be a disconnect in fixing those issues with the static values. We also agree that there is not an easy solution. In specific: (a) The static CB ratio might not incentivize BAs to improve response with increased inertia or faster responding governing response. (b) The static withdrawal BC'adj may not incentivize BAs to improve their governing response and limit their withdrawal. Improved technology may allow for better measurement to account for these issues dynamically rather than using static numbers. Guidance on increasing inertia, increasing governing speed, and reducing withdrawal should be considered by stakeholders. We thank NERC and the SDT for the opportunity to provide comments on this important standard.
Response: Thank you for your comments. **(1) The standard as presently written addresses both over and under frequency events.** **(2) The credit given for LCR is based on numbers provided by the interconnection. The utilization of load by any individual BA will be included in the calculation of their FRM through the Net Actual Interchange term rather than the IFRO.** **(3) Thank you for your comment.** **(4) Please refer to our response to (2) above.** **(5) Thank you for your comment. As more information is gained through implementation of this standard modifications based on this information will be possible.**	
Ameren	While we support this draft, we believe that this might only be a starting point and as additional knowledge and experience is gained through the implementation of this standard and other efforts such as the FRI, that the improvements can be embraced by all parties, even if those improvements result in relaxed requirements.
Response: Thank you for your comments. The NERC process allows for adjustments and improvements for both its thresholds and	

Organization	Question 9 Comment
methodologies when operational experience has been gained.	
Xcel Energy	Xcel Energy supports this proposed revision to the standard as a first step and suggests that after operating for a couple of years under the revised standard, that NERC initiates a more complete study to support any modifications to the standard.
Response: Thank you for your comment. The drafting team agrees.	

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. The Standards Committee approved the SAR for posting on January 13, 2005.
2. The SAR was posted for industry comment from January 17, 2005 through February 17, 2005.
3. Reply comments and a revised SAR were posted for a second industry comment period from April 4, 2006 through May 3, 2006.
4. Reply comments and a revised SAR were posted for a third industry comment period from February 8, 2007 through March 9, 2007.
5. Standards Committee approved moving the project into the standards development phase on July 12, 2007.
6. The Standards Committee appointed the Standard Drafting Team on August 13, 2007.
7. The draft standard was posted for a 30 day formal comment period from February 4, 2011 through March 7, 2011.
8. The draft standard was posted for a 45-day formal comment period and a 10 day initial ballot from October 25, 2011 through December 8, 2011.

Proposed Action Plan and Description of Current Draft:

This is the third posting of the proposed standard and its associated documents for a 30 day formal comment period and a successive 10 day ballot, from October 5, 2012 through November 5, 2012.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Respond to comments submitted within the comment period and with the successive ballot.	December, 2012
2. Conduct a recirculation ballot for ten days.	December, 2012
3. BOT adoption.	February, 2013

Definitions of Terms used in the Standard

Frequency Response Measure (FRM)

The median of all the Frequency Response observations reported annually by Balancing Authorities or Frequency Response Sharing Groups for frequency events specified by the ERO. This will be calculated as MW/0.1Hz.

Frequency Response Obligation (FRO)

The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection. This will be calculated as MW/0.1Hz.

Frequency Bias Setting

A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's inverse Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems.

Frequency Response Sharing Group (FRSG)[1]

A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.

[1] This term and definition is identical to the definition in BAL-012-1 proposed standard.

A. Introduction

Title: Frequency Response and Frequency Bias Setting

Number: BAL-003-1

Purpose: To require sufficient Frequency Response from the Balancing Authority (BA) to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to its scheduled value. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Applicability:

1.1. Balancing Authority

1.1.1 The Balancing Authority is the responsible entity unless the Balancing Authority is a member of a Frequency Response Sharing Group, in which case, the Frequency Response Sharing Group becomes the responsible entity.

1.2. Frequency Response Sharing Group

Effective Date:

1.3. In those jurisdictions where regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.

1.4. In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

B. Requirements

R1. Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation. *[Risk Factor: Medium][Time Horizon: Real-time Operations]*

R2. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined in accordance with Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO and shall use this Frequency Bias Setting until directed to change by the ERO. *[Risk Factor: Medium][Time Horizon: Operations Planning]*

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and is utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is: *[Risk Factor: Medium][Time Horizon: Operations Planning]*

3.1 Less than zero at all times, and

3.2 Equal to or more negative than its Frequency Response Obligation when Frequency varies from 60 Hz by more than +/- 0.036 Hz.

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to either: *[Risk Factor: Medium][Time Horizon: Operations Planning]*

- The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or
- The Frequency Bias Setting shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities' Areas.

C. Measures

M1. Each Frequency Response Sharing Group or Balancing Authority that is not a member of a Frequency Response Sharing Group shall have evidence such as dated data plus documented formula in either hardcopy or electronic format that it achieved an annual FRM (in accordance with the methods specified by the ERO in Attachment A with data from FRS Form 1 reported to the ERO as specified in Attachment A) that is equal to or more negative than its FRO to demonstrate compliance with Requirement R1.

M2. The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service shall have evidence such as a dated document in hard copy or electronic format showing the ERO validated Frequency Bias Setting was implemented into its ACE calculation within the implementation period specified or other evidence to demonstrate compliance with Requirement R2.

M3. The Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and is utilizing variable Frequency Bias shall have evidence such as a dated report in hard copy or electronic format showing the average clock-minute average Frequency Bias Setting was less than zero and during periods when the clock-minute average frequency was outside of

the range 59.964 Hz to 60.036 Hz was equal to or more negative than its Frequency Response Obligation to demonstrate compliance with Requirement R3.

M4. The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format showing that when it performed Overlap Regulation Service, it modified its Frequency Bias Setting in its ACE calculation as specified in Requirement R4 to demonstrate compliance with Requirement R4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

The Regional Entity is the Compliance Enforcement Authority except where the responsible entity works for the Regional Entity. Where the responsible entity works for the Regional Entity, the Regional Entity will establish an agreement with the ERO or another entity approved by the ERO and FERC (i.e. another Regional Entity), to be responsible for compliance enforcement.

1.2. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Investigation

Self-Reporting

Complaints

1.3. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Balancing Authority shall retain data or evidence to show compliance with Requirements R1, R2, R3 and R4, Measures M1, M2, M3 and M4 for the current year plus the previous three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Frequency Response Sharing Group shall retain data or evidence to show compliance with Requirement R1 and Measure M1 for the current year plus the previous three calendar years unless directed by its Compliance Enforcement

Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Balancing Authority or Frequency Response Sharing Group is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

1.4. Additional Compliance Information

For Interconnections that are also Balancing Authorities, Tie Line Bias control and flat frequency control are equivalent and either is acceptable.

2.0 Violation Severity Levels

R#	Lower VSL	Medium VSL	High VSL	Severe VSL
R1	The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's IFRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 1% but by at most 30% or 15 MW/0.1 Hz, whichever one is the greater deviation from its FRO	The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's IFRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 30% or by more than 15 MW/0.1 Hz, whichever is the greater deviation from its FRO	The summation of the Balancing Authorities' FRM within an Interconnection did not meet its IFRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 1% but by at most 30% or 15 MW/0.1 Hz, whichever one is the greater deviation from its FRO	The summation of the Balancing Authorities' FRM within an Interconnection did not meet its IFRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 30% or by more than 15 MW/0.1 Hz, whichever is the greater deviation from its FRO

Attachment A

BAL-003-1 Frequency Response & Frequency Bias Setting Standard

Supporting Document

Interconnection Frequency Response Obligation (IFRO)

The ERO, in consultation with regional representatives, has established a target contingency protection criterion for each Interconnection called the Interconnection Frequency Response Obligation (IFRO). The default IFRO listed in Table 1 is based on the resource contingency criteria (RCC), which is the largest category C (N-2) event identified except for the Eastern Interconnection, which uses the largest event in the last 10 years. A maximum delta frequency (MDF) is calculated by adjusting a starting frequency for each Interconnection by the following:

- Prevailing UFLS first step
- CC_{Adj} which is the adjustment for the differences between 1-second and sub-second Point C observations for frequency events. A positive value indicates that the sub-second C data is lower than the 1-second data
- CB_R which is the statistically determined ratio of the Point C to Value B
- BC'_{Adj} which is the statistically determined adjustment for the event nadir being below the Value B (Eastern Interconnection only) during primary frequency response withdrawal.

The IFRO for each Interconnection in Table 1 is then calculated by dividing the RCC MWs by 10 times the MDF. In the Eastern Interconnection there is an additional adjustment (BC'_{Adj}) for the event nadir being below the Value B due to primary frequency response withdrawal. This IFRO includes uncertainty adjustments at a 95 % confidence level. Detailed descriptions of the calculations used in Table 1 below are defined in the *Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard*.

Interconnection	Eastern	Western	ERCOT	HQ	Units
Starting Frequency (F_{Start})	**59.974**	**59.976**	**59.963**	**59.972**	Hz
Prevailing UFLS First Step	**59.5***	**59.5**	**59.3**	**58.5**	Hz
Base Delta Frequency (DF_{Base})	**0.474**	**0.476**	**0.663**	**1.472**	Hz
CC_{ADJ}	**0.007**	**0.004**	**0.012**	**N/A**	Hz
Delta Frequency (DF_{CC})	**0.467**	**0.472**	**0.651**	**1.472**	Hz
CB_R	**1.000**	**1.625**	**1.377**	**1.550**	

Delta Frequency (DF_{CBR})	**0.467**	**0.291**	**0.473**	**0.949**	Hz
BC'_{ADJ}	**0.018**	**N/A**	**N/A**	**N/A**	Hz
Max. Delta Frequency (MDF)	**0.449**	**0.291**	**0.473**	**0.949**	
Resource Contingency Criteria (RCC)	**4,500**	**2,740**	**2,750**	**1,700**	MW
Credit for Load Resources (CLR)		**300**	**1,400****		MW
IFRO	**-1,002**	**-840**	**-286**	**-179**	MW/0.1 Hz

Table 1: Interconnection Frequency Response Obligations

**The Eastern Interconnection UFLS set point listed is a compromise value set midway between the stable frequency minimum established in PRC-006-1 (59.3 Hz) and the local protection UFLS setting of 59.7 Hz used in Florida and Manitoba.*

***In the Base Obligation measure for ERCOT, 1400 MW (Load Resources triggered by Under Frequency Relays at 59.70 Hz) was reduced from its Resource Contingency Criteria level of 2750 MW to get 239 MW/0.1 Hz. This was reduced to accurately account for designed response from Load Resources within 30 cycles.*

An Interconnection may propose alternate IFRO protection criteria to the ERO by submitting a SAR with supporting technical documentation.

Balancing Authority Frequency Response Obligation (FRO) and Frequency Bias Setting

The ERO will manage the administrative procedure for annually assigning an FRO and implementation of the Frequency Bias Setting for each Balancing Authority. The annual timeline for all activities described in this section are shown below.

For a multiple Balancing Authority interconnection, the Interconnection Frequency Response Obligation shown in Table 1 is allocated based on the Balancing Authority annual load and annual generation. The FRO allocation will be based on the following method:

$$\mathrm{FRO_{BA}} = \mathrm{IFRO} \times \frac{\mathrm{Annual\ Gen_{BA}} + \mathrm{Annual\ Load_{BA}}}{\mathrm{Annual\ Gen_{Int}} + \mathrm{Annual\ Load_{Int}}}$$

Where:

- Annual Gen_{BA} is the total annual "Output of Generating Plants" within the Balancing Authority Area (BAA), on FERC Form 714, column c of Part II - Schedule 3.
- Annual $Load_{BA}$ is total annual Load within the BAA, on FERC Form 714, column e of Part II - Schedule 3.
- Annual Gen_{Int} is the sum of all Annual Gen_{BA} values reported in that interconnection.
- Annual $Load_{Int}$ is the sum of all Annual $Load_{BA}$ values reported in that interconnection.

The data used for this calculation is from the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which utilized data from 2011.

Balancing Authorities that are not FERC jurisdictional should use the Form 714 Instructions to assemble and submit equivalent data to the ERO for use in the FRO Allocation process.

Balancing Authorities that elect to form a FRSG will calculate a FRSG FRO by adding together the individual BA FRO's.

Balancing Authorities that elect to form a FRSG as a means to jointly meet the FRO will calculate their FRM performance one of two ways:

- Calculate a group NI_A and measure the group response to all events in the reporting year on a single FRS Form 1, or
- Jointly submit the individual BAs' Form 1s, with a summary spreadsheet that contains the sum of each participant's individual event performance.

Balancing Authorities that merge or that transfer load or generation are encouraged to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation to the Interconnection remains the same and so that CPS limits can be adjusted.

Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO each year to allow the ERO to validate the revised Frequency Bias Settings on FRS Form 1. If the ERO posts the official list of events after the date specified in the timeline below, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to submit their FRS Form 1.

Once the ERO reviews the data submitted in FRS Form 1 and FRS Form 2 for all Balancing Authorities, the ERO will use FRS Form 1 data to post the following information for each Balancing Authority for the upcoming year:

- Frequency Bias Setting
- Frequency Response Obligation (FRO)

Once the data listed above is fully posted, the ERO will announce the three-day implementation period for changing the Frequency Bias Setting if it differs from that shown in the timeline below.

A BA using a fixed Frequency Bias Setting sets its Frequency Bias Setting to the greater of (in absolute value):

- Any number the BA chooses between 100% and 125% of its Frequency Response Measure as calculated on FRS Form 1
- Interconnection Minimum as determined by the ERO

For purposes of calculating the minimum Frequency Bias Setting, a Balancing Authority participating in a Frequency Response Sharing Group will need to calculate its stand-alone Frequency Response Measure using FRS Form 1 and FRS Form 2 to determine its minimum Frequency Bias Setting.

A Balancing Authority providing Overlap Regulation will report the historic peak demand and generation of its combined BAs' areas on FRS Form 1 as described in Requirement R4.

There are occasions when changes are needed to Bias Settings outside of the normal schedule. Examples are footprint changes between Balancing Authorities and major changes in load or generation or the formation of new Balancing Authorities. In such cases the changing Balancing Authorities will work with their Regions, NERC and the Resources Subcommittee to confirm appropriate changes to Bias Settings, FRO, CPS limits and Inadvertent Interchange balances.

If there is no net change to the Interconnection total Bias, the Balancing Authorities involved will agree on a date to implement their respective change in Bias Settings. The Balancing Authorities and ERO will also agree to the allocation of FRO such that the sum remains the same.

If there is a net change to the Interconnection total Bias, this will cause a change in CPS2 limits and FRO for other Balancing Authorities in the Interconnection. In this case, the ERO will notify the impacted Balancing Authorities of their respective changes and provide an implementation window for making the Bias Setting changes.

Frequency Response Measure (FRM)

The Balancing Authority will calculate its FRM from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz" as calculated on FRS Form 2 for each event shown on FRS Form 1. The events in FRS Form 1 are selected by the ERO using the *Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard*. The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change in its Net Actual Interchange on its tie lines with its adjacent Balancing Authorities divided by the change in Interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their Net Actual Interchange (NA_I) values to account for factors such as nonconforming loads. FRS Form 1 and 2 shows the types of adjustments that are allowed. Note that with the exception of the Contingent BA column, any adjustments made must be made for all events in an evaluation year. As an example, if an entity has non-conforming loads and makes an adjustment for one event, all events must show the non-conforming load, even if the non-conforming load does not impact the calculation. This ensures that the reports are not utilizing the adjustments only when they are favorable to the BA.) The ERO will use a standardized sampling interval of approximately 16 seconds before the event up to the time of the event for the pre-event NA_I, and frequency (A values) and approximately 20 to 52 seconds after the event for the post-event NA_I (B values) in the computation of SEFRD values, dependent on the data scan rate of the Balancing Authority's Energy Management System (EMS).

All events listed on FRS Form 1 need to be included in the annual submission of FRS Forms 1 and 2. The only time a Balancing Authority should exclude an event is if its tie-line data or its Frequency data is corrupt or its EMS was unavailable. FRS Form 2 has instructions on how to correct the BA's data if the given event is internal to the BA or if other authorized adjustments are used.

Assuming data entry is correct FRS Form 1 will automatically calculate the Balancing Authority's FRM for the past 12 months as the median of the SEFRD values. A Balancing Authority electing to report as an FRSG or a provider of Overlap Regulation Service will provide an FRS Form 1 for the aggregate of its participants.

To allow Balancing authorities to plan its operations, events with a "Point C" that cause the Interconnection Frequency to be lower than that shown in Table 1 above (for example, an event in the Eastern Interconnection that causes the Interconnection Frequency to go to 59.4 Hz) or higher than an equal change in frequency going above 60 Hz may be included in the list of events for that interconnection. However, the calculation of the BA response to such an event will be adjusted to show a frequency change only to the Target Minimum Frequency shown in Table 1 above (in the previous example this adjustment would cause Frequency to be shown as 59.5 Hz rather than 59.4 HZ) or a high frequency amount of an equal quantity. Should such an event happen, the ERO will provide additional guidance.

Timeline for Balancing Authority Frequency Response and Frequency Bias Setting Activities

Described below is the timeline for the exchange of information between the ERO and Balancing Authorities (BA) to:

- Facilitate the assignment of BA Frequency Response Obligations (FRO)
- Calculate BA Frequency Response Measures (FRM)
- Determine BA Frequency Bias Settings (FBS)

Target Date	Activity
April 30	The ERO reviews candidate frequency events and selects frequency events for the first quarter (December to February).
May 10	Form1 is posted with selected events from the first quarter for BA usage by the ERO.
May 15	The BAs receive a request to provide load and generation data as described in Attachment A to support FRO assignments and determining minimum FBS for BAs.
July 15	The BAs provide load and generation data as described in Attachment A to the ERO.
July 30	The ERO reviews candidate frequency events and selects frequency events for the second quarter (March to May).
August 10	Form1 is posted with selected events from the first and second quarters for BA usage by the ERO.
October 30	The ERO reviews candidate frequency events and selects frequency events for the third quarter (June to August)
November 10	Form1 is posted with selected events from the first, second, and third quarters for BA usage by the ERO.
November 20	If necessary, the ERO provides any updates to the necessary Frequency Response.
November 20	The ERO provides the fractional responsibility of each BA for the Interconnection's FRO and Minimum FBS to the BAs.
January 30	The ERO reviews candidate frequency events and selects frequency events for the fourth quarter (September to November).

2nd business day in February	Form1 is posted with all selected events for the year for BA usage by the ERO.
February 10	The ERO assigns FRO values to the BAs for the upcoming year.
March 7	BAs complete their frequency response sampling for all four quarters and their FBS calculation, returning the results to the ERO.
March 24	The ERO validates FBS values, computes the sum of all FBS values for each Interconnection, and determines L10 values for the CPS 2 criterion for each BA as applicable.
Any time during first 3 business days of April (unless specified otherwise by the ERO)	The BA implements any changes to their FBS and L10 value.

Attachment A

BAL-003-1 Frequency Response & Frequency Bias Setting Standard

Supporting Document

Interconnection Frequency Response Obligation (IFRO) ~~for the Interconnection~~

The ERO, in consultation with regional representatives, has established a target contingency protection criterion for each Interconnection called the Interconnection Frequency Response Obligation (IFRO). The default IFRO~~target~~ listed in Table 1 is based on the resource contingency criteria (RCC), which is the largest category C (N-2) event identified except for the Eastern Interconnection, which uses the largest event in the last 10 years. A maximum delta frequency (MDF) is calculated by adjusting a starting frequency for each Interconnection by the following:

- Prevailing UFLS first step
- CC_{Adj} which is the adjustment for the differences between 1-second and sub-second Point C observations for frequency events. A positive value indicates that the sub-second C data is lower than the 1-second data
- CB_R which is the statistically determined ratio of the Point C to Value B
- BC'_{Adj} which is the statistically determined adjustment for the event nadir being below the Value B (Eastern Interconnection only) during primary frequency response withdrawal.

~~Additionally, this contingency protection criterion includes uncertainty adjustments at a 95 % confidence level to prevent Point C from encroaching on the interconnection's highest Under Frequency Load Shed (UFLS) step for credible contingencies.~~ The IFRO~~Obligation~~ for each Interconnection in Table 1 is then calculated by dividing the RC~~Target Protection C~~riteria MWs by 10 times the MDF~~difference between the starting frequency and the Prevailing UFLS First Step~~. ~~This number is then multiplied by the C to B Ratio to arrive at a MW/0.1 Hz number.~~ In the Eastern Interconnection there is an additional adjustment (BC'_{Adj}) for the event nadir being below the Value B due to primary frequency response withdrawal. This ~~Interconnection Frequency Response Obligation (~~IFRO~~)~~ includes uncertainty adjustments at a 95 % confidence level. Detailed descriptions of the calculations used in Table 1 below are defined in the *Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard*.

Interconnection	Eastern	Western	ERCOT	HQ	Units

Starting Frequency (F_{Start})	**59.974**	**59.976**	**59.963**	**59.972**	Hz
Prevailing UFLS First Step	**59.5***	**59.5**	**59.3**	**58.5**	Hz
Base Delta Frequency (DF_{Base})	**0.474**	**0.476**	**0.663**	**1.472**	Hz
CC_{ADJ}	**0.007**	**0.004**	**0.012**	**N/A**	Hz
Delta Frequency (DF_{CC})	**0.467**	**0.472**	**0.651**	**1.472**	Hz
CB_R	**1.000**	**1.625**	**1.377**	**1.550**	~~Hz~~
Delta Frequency (DF_{CBR})	**0.467**	**0.291**	**0.473**	**0.949**	Hz
BC'_{ADJ}	**0.018**	**N/A**	**N/A**	**N/A**	Hz
Max. Delta Frequency (MDF)	**0.449**	**0.291**	**0.473**	**0.949**	
Resource Contingency Criteria (RCC)	**4,500**	**2,740**	**2,750**	**1,700**	MW
Credit for Load Resources (CLR)		**300**	**1,400****		MW
IFRO	**-1,002**	**-840**	**-286**	**-179**	MW/0.1 Hz

Table 1: Interconnection Frequency Response Obligations

**The Eastern Interconnection UFLS set point listed is a compromise value set midway between the stable frequency minimum established in PRC-006-1 (59.3 Hz) and the local protection UFLS setting of 59.7 Hz used in Florida and Manitoba.*

***In the Base Obligation measure for ERCOT, 1400 MW (Load Resources triggered by Under Frequency Relays at 59.70 Hz) was reduced from its Resource Contingency ~~Protection~~ Criteria level of 2750 MW to get 239 MW/0.1 Hz. This was reduced to accurately account for designed response from Load Resources within 30 cycles.*

An Interconnection may propose alternate IFRO protection criteria to the ERO by submitting a SAR with supporting technical documentation.

Balancing Authority Frequency Response Obligation (FRO) and Frequency Bias Setting

The ERO will manage the administrative procedure for annually assigning an FRO and implementation of the Frequency Bias Setting for each Balancing Authority. The annual timeline for all activities described in this section are shown below.

For a multiple Balancing Authority interconnection, the Interconnection Frequency Response Obligation shown in Table 1 is allocated based on the Balancing Authority annual load and annual generation. The FRO allocation will be based on the following method:

$$\text{FRO}_{\text{BA}} = \text{IFRO}_{\text{~~Int~~}} \times \frac{\text{Annual Gen}_{\text{BA}} + \text{Annual Load}_{\text{BA}}}{\text{Annual Gen}_{\text{Int}} + \text{Annual Load}_{\text{Int}}}$$

Where:

- Annual Gen_{BA} is the total annual "Output of Generating Plants" within the Balancing Authority Area (BAA), on FERC Form 714, column c of Part II - Schedule 3.
- Annual $Load_{BA}$ is total annual Load within the BAA, on FERC Form 714, column e of Part II - Schedule 3.
- Annual Gen_{Int} is the sum of all Annual Gen_{BA} values reported in that interconnection.
- Annual $Load_{Int}$ is the sum of all Annual $Load_{BA}$ values reported in that interconnection.

The data used for this calculation is from the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which utilized data from 2011.

Balancing Authorities that are not FERC jurisdictional should use the Form 714 Instructions to assemble and submit equivalent data to the ERO for use in the FRO Allocation process.

Balancing Authorities that elect to form a FRSG will calculate a FRSG FRO by adding together the individual BA FRO's.

Balancing Authorities that elect to form a FRSG as a means to jointly meet the FRO will calculate their FRM performance one of two ways:

- Calculate a group NI_A and measure the group response to all events in the reporting year on a single FRS Form 1, or
- Jointly submit the individual BAs' Form 1s, with a summary spreadsheet that ~~that~~ contains the sum of each participant's individual event performance.

Balancing Authorities that merge or that transfer load or generation are encouraged to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation to the Interconnection remains the same and so that CPS limits can be adjusted.

Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO each year to allow the ERO to validate the revised Frequency Bias Settings on FRS Form 1. If the ERO posts the official list of events after the date specified in the timeline below, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to submit their FRS Form 1.

Once the ERO reviews the data submitted in FRS Form 1 and FRS Form 2 for all Balancing Authorities, the ERO will use FRS Form 1 data to post the following information for each Balancing Authority for the upcoming year:

- Frequency Bias Setting
- Frequency Response Obligation (FRO)

Once the data listed above is fully posted, the ERO will announce the three-day implementation period for changing the Frequency Bias Setting if it differs from that shown in the timeline below.

A BA using a fixed Frequency Bias Setting sets its Frequency Bias Setting to the greater of (in absolute value):

- Any number the BA chooses between 100% and 125% of its Frequency Response Measure as calculated on FRS Form 1
- Interconnection Minimum as determined by the ERO

For purposes of calculating the minimum Frequency Bias Setting, a Balancing Authority participating in a Frequency Response Sharing Group will need to calculate its stand-alone Frequency Response Measure using FRS Form 1 and FRS Form 2 to determine its minimum Frequency Bias Setting.

A Balancing Authority providing Overlap Regulation will report the historic peak demand and generation of its combined BAs' areas on FRS Form 1 as described in Requirement R4.

There are occasions when changes are needed to Bias Settings outside of the normal schedule. Examples are footprint changes between Balancing Authorities and major changes in load or generation or the formation of new Balancing Authorities. In such cases the changing Balancing Authorities will work with their Regions, NERC and the Resources Subcommittee to confirm appropriate changes to Bias Settings, FRO, CPS limits and Inadvertent Interchange balances.

If there is no net change to the Interconnection total Bias, the Balancing Authorities involved will agree on a date to implement their respective change in Bias Settings. The Balancing Authorities and ERO will also agree to the allocation of FRO such that the sum remains the same.

If there is a net change to the Interconnection total Bias, this will cause a change in CPS2 limits and FRO for other Balancing Authorities in the Interconnection. In this case, the ERO will notify the impacted Balancing Authorities of their respective changes and provide an implementation window for making the Bias Setting changes.

Frequency Response Measure (FRM)

The Balancing Authority will calculate its FRM from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz" as calculated on FRS Form 2 for each event shown on FRS Form 1. The events in FRS Form 1 are selected by the ERO using the *Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard*. The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change in its Net Actual Interchange on its tie lines with its adjacent Balancing Authorities divided by the change in Interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their Net Actual Interchange (NA_I) values to account for factors such as nonconforming loads. FRS Form 1 and 2 shows the types of adjustments that are allowed. Note that with the exception of the Contingent BA column, any adjustments made must be made for all events in an evaluation year. As an example, if an entity has non-conforming loads and makes an adjustment for one event, all events must show the non-conforming load, even if the non-conforming load does not impact the calculation. This ensures that the

reports are not utilizing the adjustments only when they are favorable to the BA.) The ERO will use a standardized sampling interval of approximately 16 seconds before the event up to the time of the event for the pre-event NA_I, and frequency (A values) and approximately 20 to 52 seconds after the event for the post-event NA_I (B values) in the computation of SEFRD values, dependent on the data scan rate of the Balancing Authority's Energy Management System (EMS).

All events listed on FRS Form 1 need to be included in the annual submission of FRS Forms 1 and 2. The only time a Balancing Authority should exclude an event is if its tie-line data or its Frequency data is corrupt or its EMS was unavailable. FRS Form 2 has instructions on how to correct the BA's data if the given event is internal to the BA or if other authorized adjustments are used.

Assuming data entry is correct FRS Form 1 will automatically calculate the Balancing Authority's FRM for the past 12 months as the median of the SEFRD values. A Balancing Authority electing to report as an FRSG or a provider of Overlap Regulation Service will provide an FRS Form 1 for the aggregate of its participants.

To allow Balancing authorities to plan its operations, events with a "Point C" that cause the Interconnection Frequency to be lower than that shown in Table 1 above (for example, an event in the Eastern Interconnection that causes the Interconnection Frequency to go to 59.4 Hz) or higher than an equal change in frequency going above 60 Hz may be included in the list of events for that interconnection. However, the calculation of the BA response to such an event will be adjusted to show a frequency change only to the Target Minimum Frequency shown in Table 1 above (in the previous example this adjustment would cause Frequency to be shown as 59.5 Hz rather than 59.4 HZ) or a high frequency amount of an equal quantity. Should such an event happen, the ERO will provide additional guidance.

Timeline for Balancing Authority Frequency Response and Frequency Bias Setting Activities

Described below is the timeline for the exchange of information between the ERO and Balancing Authorities (BA) to:

- Facilitate the assignment of BA Frequency Response Obligations (FRO)
- Calculate BA Frequency Response Measures (FRM)
- Determine BA Frequency Bias Settings (FBS)

Target Date	Activity
April 30	The ERO reviews candidate frequency events and selects frequency events for the first quarter (December to February).
May 10	Form1 is posted with selected events from the first quarter for BA usage by the ERO.
May 15	The BAs receive a request to provide load and generation data as described in Attachment A to support FRO assignments and determining minimum FBS for BAs.
July 15	The BAs provide load and generation data as described in Attachment A to the ERO.
July 30	The ERO reviews candidate frequency events and selects frequency events for the second quarter (March to May).
August 10	Form1 is posted with selected events from the first and second quarters for BA usage by the ERO.
October 30	The ERO reviews candidate frequency events and selects frequency events for the third quarter (June to August)
November 10	Form1 is posted with selected events from the first, second, and third quarters for BA usage by the ERO.
November 20	If necessary, the ERO provides any updates to the necessary Frequency Response.
November 20	The ERO provides the fractional responsibility of each BA for the Interconnection's FRO and Minimum FBS to the BAs.
January 30	The ERO reviews candidate frequency events and selects frequency events for the fourth quarter (September to November).

2nd business day in February	Form1 is posted with all selected events for the year for BA usage by the ERO.
February 10	The ERO assigns FRO values to the BAs for the upcoming year.
March 7	BAs complete their frequency response sampling for all four quarters and their FBS calculation, returning the results to the ERO.
March 24	The ERO validates FBS values, computes the sum of all FBS values for each Interconnection, and determines L10 values for the CPS 2 criterion for each BA as applicable.
Any time during first 3 business days of April (unless specified otherwise by the ERO)	The BA implements any changes to their FBS and L10 value.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Implementation Plan for BAL-003-1 – Frequency Response & Frequency Bias Setting Standard

Prerequisite Approvals

There are no other reliability standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

Modified Standards

BAL-003-0.1b should be retired midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

New or Modified Definitions

The following definitions shall become effective when BAL-003-1 Requirements R2, R3, R4 and R5 become effective:

Frequency Response Measure (FRM): The median of all the Frequency Response observations reported annually by Balancing Authorities for frequency events specified by the ERO. This will be calculated as MW/0.1Hz.

Frequency Response Obligation (FRO): The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection. This will be calculated as MW/0.1Hz.

Frequency Bias Setting: A number, either fixed or variable, , usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's inverse Frequency Response contribution to the Interconnection, and discourage withdrawal through secondary control systems.

Frequency Response Sharing Group (FRSG)[1]: A group, whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the Frequency Response Obligations of its members.

The existing definition of Frequency Bias Setting should be retired midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

[1] This term and definition is identical to the definition in BAL-012-1 proposed standard.

116-390 Village Boulevard, Princeton, New Jersey 08540-5721
Phone: 609.452.8060 ▪ Fax: 609.452.9550 ▪ www.nerc.com

The proposed revised definition for "Frequency Bias Setting" is incorporated in the following NERC approved standards:

- BAL-001-0.1a Real Power Balancing Control Performance
- BAL-004-0 Time Error Correction
- BAL-004-1 Time Error Correction
- BAL-005-0.1b Automatic Generation Control

Compliance with Standards

Once this standard becomes effective, the responsible entities identified in the applicability section of the standard must comply with the requirements. These include:

- Balancing Authorities
- Frequency Response Sharing Groups

Proposed Effective Date

Compliance with BAL-003-1 shall be implemented over a two-year period, as follows:

- In those jurisdictions where regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.
- Requirement R1 cannot be implemented prior to the addition of Frequency Response Sharing Group to the Compliance Registry.

In those jurisdictions where no regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.
- Requirement R1 cannot be implemented prior to the addition of Frequency Response Sharing Group to the Compliance Registry.

This procedure outlines the Electric Reliability Organization (ERO) process for supporting the Frequency Response Standard (FRS). A Procedure revision request may be submitted to the ERO for consideration. The revision request must provide a technical justification for the suggested modification. The ERO shall post the suggested modification for a 45-day formal comment period and discuss the revision request in a public meeting. The ERO will make a recommendation to the NERC BOT, which may adopt the revision request, reject it, or adopt it with modifications. Any approved revision to this Procedure shall be filed with FERC for informational purposes.

Event Selection Process

Event Selection Objectives

The goals of this procedure are to outline a transparent, repeatable process to annually identify a list of frequency events to be used by Balancing Authorities (BA) to calculate their Frequency Response to determine:

- Whether the BA met its Frequency Response Obligation, and
- An appropriate fixed Bias Setting.

Event Selection Criteria

1. The ERO will use the following criteria to select FRS frequency excursion events for analysis. The events that best fit the criteria will be used to support the FRS. The evaluation period for performing the annual Frequency Bias Setting and the Frequency Response Measure (FRM) calculation is December 1 of the prior year through November 30 of the current year.
2. The ERO will identify 20 to 35 frequency excursion events in each Interconnection for calculating the Frequency Bias Setting and the FRM. If the ERO cannot identify 20 frequency excursion events in a 12 month evaluation period satisfying the criteria below, then similar acceptable events from the subsequent year's evaluation period will be included with the data set by the ERO for determining FRS compliance. This is described later.
3. The ERO will use three criteria to determine if an acceptable frequency excursion event for the FRM has occurred:
    a. The change in frequency as defined by the difference from the A Value to Point C and the arrested frequency Point C exceeds the excursion threshold values specified for the Interconnection in Table 1 below.
        i. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline.
        ii. Point C is the arrested value of frequency observed within 12 seconds following the start of the excursion.

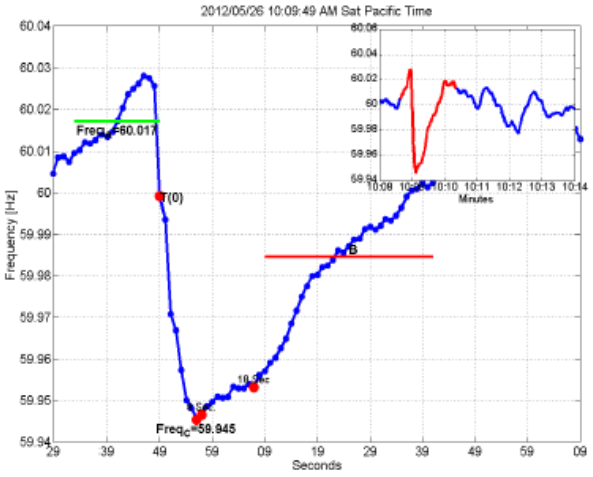
Interconnection	A Value to Pt C	Point C (Low)	Point C (High)
East	0.04Hz	< 59.96	> 60.04
West	0.07Hz	< 59.95	> 60.05
ERCOT	0.15Hz	< 59.90	> 60.10
HQ	0.30Hz	< 59.85	> 60.15

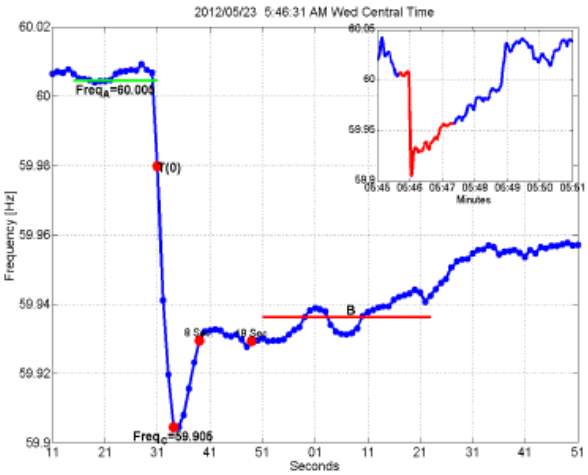
Table 1: Interconnection Frequency Excursion Threshold Values

b. The time from the start of the rapid change in frequency until the point at which Frequency has stabilized within a narrow range should be less than 18 seconds.

c. If any data point in the B Value average recovers to the A Value, the event will not be included.

4. Pre-disturbance frequency should be relatively steady and near 60.000 Hz for the A Value. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline. For example, given the choice of the two events below, the one on the right is preferred as the pre-disturbance frequency is stable and also closer to 60 Hz.





5. Excursions that include 2 or more events that do not stabilize within 18 seconds will not be considered.

6. Frequency excursion events occurring during periods:

(i) when large in*t*erchange schedule ramping or load change is happening, or

(ii) *w*ithin 5 minutes of the top of the hour,

will be excluded from consideration if other acceptable frequency excursion events from the same quarter are available.

7. The ERO will select the largest (A Value to Point C) 2 or 3 frequency excursion *e*vents occurring each month. If there are not 2 frequency excursion events satisfying the selection criteria in a month, then other frequency excursion events should be picked in the following sequence:
    a. From the same event quarter of the year.
    b. From an adjacent month.
    c. From a similar load season in the year (shoulder vs. summer/winter)
    d. The largest unused event.

As noted earlier, if a total of 20 events are not available in an evaluation year, then similar acceptable events from the next year's evaluation period will be included with the data set by the ERO for determining Frequency Response Obligation (FRO) compliance. The first year's small set of data will be reported and used for Bias Setting purposes, but compliance evaluation on the FRO will be done using a 24 month data set.

To assist Balancing Authority preparation for complying with this standard, the ERO will provide quarterly posting of candidate frequency excursion events for the current year FRM calculation. The ERO will post the final list of frequency excursion events used for standard compliance as specified in Attachment A of BAL-003-1. The following is a general description of the process that the ERO will use to ensure that BAs can evaluate events during the year in order to monitor their performance throughout the year.

Monthly

Candidate events will be initially screened by the "Frequency Event Detection Methodology" shown on the following link located on the NERC Resources Subcommittee area of the NERC website: http://www.nerc.com/docs/oc/rs/Frequency_Event_Detection_Methodology_and_Criteria_Oct_2011.pdf. Each month's list will be posted by the end of the following month on the NERC website, http://www.nerc.com/filez/rs.html and listed under "Candidate Frequency Events".

Quarterly

The monthly event lists will be reviewed quarterly with the quarters defined as:

- December through February
- March through May
- June through August
- September through November

Based on criteria established in the "*Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard",* events will be selected to populate the FRS Form 1 for each Interconnection. The Form 1's will be posted on the NERC website, in the Resources Subcommittee area under the title "Frequency Response Standard Resources". Updated Form 1's will be posted at the end of each quarter listed above after a review by the NERC RS' Frequency Working Group. While the events on this list are expected to be final, as outlined in the selection criteria, additional events may be considered, if the number of events throughout the year do not create a list of at least 20 events. It is intended that this quarterly posting of updates to the FRS Form 1 would allow BAs to evaluate the events throughout the year, lessening the burden when the yearly posting is made.

Annually

The final FRS Form 1 for each Interconnection, which would contain the events from all four quarters listed above, will be posted as specified in Attachment A. Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO as specified in Attachment A using the final FRS Form 1. The ERO will check for errors and use the FRS Form 1 data to calculate CPS limits and FROs for the upcoming year.

Once the data listed above is fully reviewed, the ERO may adjust the implementation specified in Attachment A for changing the Frequency Bias Settings and CPS limits. This allows flexibility in when each BA implements its settings.

Process for Adjusting Interconnection Minimum Frequency Bias Setting

This procedure outlines the process the ERO is to use for modifying minimum Frequency Bias Settings to better meet reliability needs. The ERO will adjust the Frequency Bias Setting minimum in accordance with this procedure.

The ERO will post the minimum Frequency Bias Setting values on the ERO website along with other balancing standard limits.

Under BAL-003-1, the minimum Frequency Bias Settings will be moved toward the natural Frequency Response in each interconnection. In the first year, the minimum Frequency Bias Setting for each interconnection is shown in Table 2 below. Each Interconnection Minimum Frequency Bias Setting is based on the sum of the non-coincident peak loads for each BA from the currently available FERC 714 Report or equivalent. This non-coincident peak load sum is multiplied by the percentage shown in Table 2 to get the Interconnection Minimum Frequency Bias Setting. The Interconnection Minimum Frequency Bias Setting is allocated among the BAs on an interconnection using the same allocation method as is used for the allocation of the Frequency Response Obligation (FRO).

Interconnection	Interconnection Minimum Frequency Bias Setting (in MW/0.1Hz)
Eastern	0.9% of non-coincident peak load
Western	0.9% of non-coincident peak load
ERCOT*	N/A
HQ*	N/A

Table 2. Frequency Bias Setting Minimums

*The minimum Frequency Bias Setting requirement does not apply to a Balancing Authority that is the only Balancing Authority in its Interconnection. These Balancing Authorities are solely responsible for providing reliable frequency control of their Interconnection. These Balancing Authorities are responsible for converting frequency error into a megawatt error to provide reliable frequency control, and the imposition of a minimum bias setting greater than the magnitude the Frequency Response Obligation may have the potential to cause control system hunting, and instability in the extreme.

The ERO, in coordination with the regions of each interconnection, will annually review Frequency Bias Setting data submitted by BAs. If an Interconnection's total minimum Frequency Bias Setting exceeds (in absolute value) the Interconnection's total natural Frequency Response by more (in absolute value) than 0.2 percentage points of peak load (expressed in MW/0.1Hz), the minimum Frequency Bias Setting for BAs within that Interconnection may be reduced (in absolute value) in the subsequent years FRS Form 1 based on the technical evaluation and consultation with the regions affected by 0.1 percentage point of peak load (expressed in MW/0.1Hz) to better match that Frequency Bias Setting and natural Frequency Response.

The ERO, in coordination with the regions of each Interconnection, will monitor the impact of the reduction of minimum frequency bias settings, if any, on frequency performance, control performance, and system reliability. If unexpected and undesirable impacts such as, but not limited to, sluggish post-contingency restoration of frequency to schedule or control performance problems occur, then the prior reduction in the minimum frequency bias settings may be reversed, and/or the prospective reduction based on the criterion stated above may not be implemented.

Interconnection Frequency Response Obligation Methodology

This procedure outlines the process the ERO is to use for determining the Interconnection Frequency Response Obligation (IFRO).

The following are the formulae that comprise the calculation of the IFROs.

$$DF_{Base} = F_{Start} - UFLS$$

$$DF_{CC} = DF_{Base} - CC_{Adj}$$

$$DF_{CBR} = \frac{DF_{CC}}{CB_R}$$

$$MDF = DF_{CBR} - BC'_{Adj}$$

$$ARCC = RCC - CLR$$

$$IFRO = \frac{ARCC}{10 * MDF}$$

Where:

- DF_{Base} is the base delta frequency.
- F_{Start} is the starting frequency determined by the statistical analysis.
- UFLS is the highest UFLS trip setpoint for the interconnection.
- CC_{Adj} is the adjustment for the differences between 1-second and sub-second Point C observations for frequency events. A positive value indicates that the sub-second C data is lower than the 1-second data.
- DF_{CC} is the delta frequency adjusted for the differences between 1-second and sub-second Point C observations for frequency events.
- CB_R is the statistically determined ratio of the Point C to Value B.
- DF_{CBR} is the delta frequency adjusted for the ratio of the Point C to Value B.
- BC'_{ADJ} is the statistically determined adjustment for the event nadir being below the Value B (Eastern Interconnection only) during primary frequency response withdrawal.
- MDF is the maximum allowable delta frequency.
- RCC is the resource contingency criteria.
- CLR is the credit for load resources.
- ARCC is the adjusted resource contingency criteria adjusted for the credit for load resources.
- IFRO is the interconnection frequency response obligation.

~~**Event Selection Process**~~

This procedure outlines the Electric Reliability Organization (ERO) process for supporting the Frequency Response Standard (FRS). A Procedure revision request may be submitted to the ERO for consideration. The revision request must provide a technical justification for the suggested modification. The ERO shall post the suggested modification for a 45-day formal comment period and discuss the revision request in a public meeting. The ERO will make a recommendation to the NERC BOT, which may adopt the revision request, reject it, or adopt it with modifications. Any approved revision to this Procedure shall be filed with FERC for informational purposes.

Event Selection Process

Event Selection Objectives

The goals of this procedure are to outline a transparent, repeatable process to annually identify a list of frequency events to be used by Balancing Authorities (BA) to calculate their Frequency Response to determine:

- Whether the BA met its Frequency Response Obligation, and
- An appropriate fixed Bias Setting.

Event Selection Criteria

1. The ERO will use the following criteria to select FRS frequency excursion events for analysis. The events that best fit the criteria will be used to support the FRS. The evaluation period for performing the annual Frequency Bias Setting and the Frequency Response Measure (FRM) calculation is December 1 of the prior year through November 30 of the current year.
2. The ERO will identify 20 to 35 frequency excursion events in each Interconnection for calculating the Frequency Bias Setting and the FRM. If the ERO cannot identify 20 frequency excursion events in a 12 month evaluation period satisfying the criteria below, then similar acceptable events from the subsequent year's evaluation period will be included with the data set by the ERO for determining FRS compliance. This is described later.
3. The ERO will use three criteria to determine if an acceptable frequency excursion event for the FRM has occurred:
    a. The change in frequency as defined by the difference from the A Value to Point C and the arrested frequency Point C exceeds the excursion threshold values specified for the Interconnection in Table 1 below.
        i. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline.
        ii. Point C is the arrested value of frequency observed within 12 seconds following the start of the excursion.

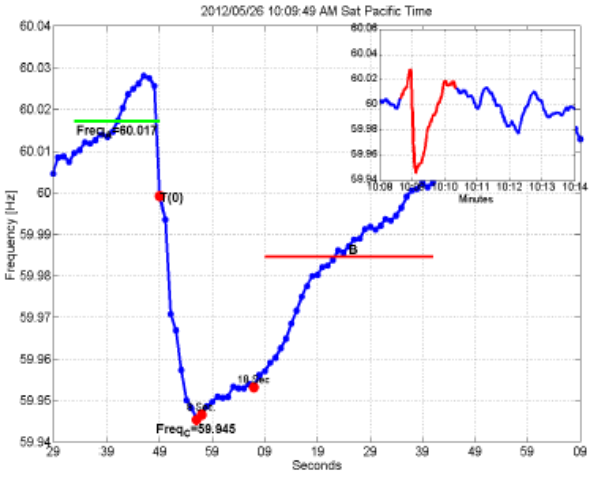
Interconnection	A Value to Pt C	Point C (Low)	Point C (High)
East	0.04Hz	< 59.96	> 60.04
West	0.07Hz	< 59.95	> 60.05
ERCOT	0.15Hz	< 59.90	> 60.10
HQ	0.30Hz	< 59.85	> 60.15

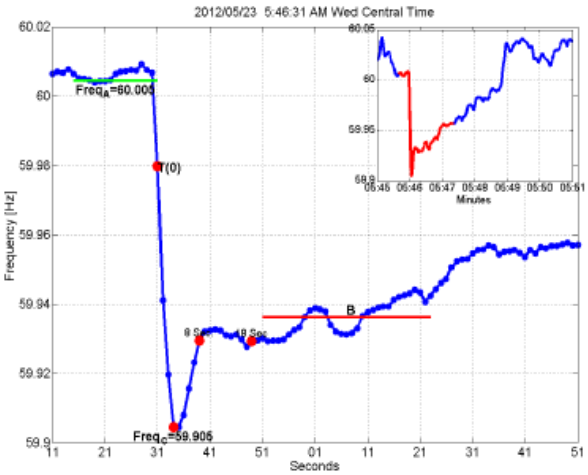
Table 1: Interconnection Frequency Excursion Threshold Values

b. The time from the start of the rapid change in frequency until the point at which Frequency has stabilized within a narrow range should be less than 18 seconds.

c. If any data point in the B Value average recovers to the A Value, the event will not be included.

4. Pre-disturbance frequency should be relatively steady and near 60.000 Hz for the A Value. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline. For example, given the choice of the two events below, the one on the right is preferred as the pre-disturbance frequency is stable and also closer to 60 Hz.





5. Excursions that include 2 or more events that do not stabilize within 18 seconds will not be considered.

6. Frequency excursion events occurring during periods:

(i) when large interchange schedule ramping or load change is happening, or

~~and frequency excursion events occurring~~ (ii) within 5 minutes of the top of the hour,

will be excluded from consideration if other acceptable frequency excursion events from the same quarter are available.

~~6.~~7. The ERO will select the largest (A Value to Point C) 2 or 3 frequency excursion *e*vents occurring each month. If there are not 2 frequency excursion events satisfying the selection criteria in a month, then other frequency excursion events should be picked in the following sequence:

a. From the same event quarter of the year.

b. From an adjacent month.

c. From a similar load season in the year (shoulder vs. summer/winter)

d. The largest unused event.

As noted earlier, if a total of 20 events are not available in an evaluation year, then similar acceptable events from the next year's evaluation period will be included with the data set by the ERO for determining Frequency Response Obligation (FRO) compliance. The first year's small set of data will be reported and used for Bias Setting purposes, but compliance evaluation on the FRO will be done using a 24 month data set.

To assist Balancing Authority preparation for complying with this standard, the ERO will provide quarterly posting of candidate frequency excursion events for the current year FRM calculation. The ERO will post the final list of frequency excursion events used for standard compliance as specified in Attachment A of BAL-003-1. The following is a general description of the process that the ERO will use to ensure that BAs can evaluate events during the year in order to monitor their performance throughout the year.

Monthly

Candidate events will be initially screened by the "Frequency Event Detection Methodology" shown on the following link located on the NERC Resources Subcommittee area of the NERC website: http://www.nerc.com/docs/oc/rs/Frequency_Event_Detection_Methodology_and_Criteria_Oct_2011.pdf. Each month's list will be posted by the end of the following month on the NERC website, http://www.nerc.com/filez/rs.html and listed under "Candidate Frequency Events".

Quarterly

The monthly event lists will be reviewed quarterly with the quarters defined as:

- December through February
- March through May
- June through August
- September through November

Based on criteria established in the "*Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard",* events will be selected to populate the FRS Form 1 for each Interconnection. The Form 1's will be posted on the NERC website, in the Resources Subcommittee area under the title "Frequency Response Standard Resources". Updated Form 1's will be posted at the end of each quarter listed above after a review by the NERC RS' Frequency Working Group. While the events on this list are expected to be final, as outlined in the selection criteria, additional events may be considered, if the number of events throughout the year do not create a list of at least 20 events. It is intended that this quarterly posting of updates to the FRS Form 1 would allow BAs to evaluate the events throughout the year, lessening the burden when the yearly posting is made.

Annually

The final FRS Form 1 for each Interconnection, which would contain the events from all four quarters listed above, will be posted as specified in Attachment A. Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO as specified in Attachment A using the final FRS Form 1. The ERO will check for errors and use the FRS Form 1 data to calculate CPS limits and FROs for the upcoming year.

Once the data listed above is fully reviewed, the ERO may adjust the implementation specified in Attachment A for changing the Frequency Bias Settings and CPS limits. This allows flexibility in when each BA implements its settings.

Process for Adjusting Interconnection Minimum Frequency Bias Setting

This procedure outlines the process the ERO is to use for modifying minimum Frequency Bias Settings to better meet reliability needs. The ERO will adjust the Frequency Bias Setting minimum in accordance with this procedure.

The ERO will post the minimum Frequency Bias Setting values on the ERO website along with other balancing standard limits.

Under BAL-003-1, the minimum Frequency Bias Settings will be moved toward the natural Frequency Response in each interconnection. In the first year, the minimum Frequency Bias Setting for each interconnection is shown in Table 2 below. Each Interconnection Minimum Frequency Bias Setting is based on the sum of the non-coincident peak loads for each BA from the currently available FERC 714 Report or equivalent. This non-coincident peak load sum is multiplied by the percentage shown in Table 2~~1~~ to get the Interconnection Minimum Frequency Bias Setting. The Interconnection Minimum Frequency Bias Setting is allocated among the BAs on an interconnection using the same allocation method as is used for the allocation of the Frequency Response Obligation (FRO).

Interconnection	Interconnection Minimum Frequency Bias Setting (in MW/0.1Hz)
Eastern	0.9% of non-coincident peak load
Western	0.9% of non-coincident peak load
ERCOT*	N/A
HQ*	N/A

Table 2. Frequency Bias Setting Minimums

*The minimum Frequency Bias Setting requirement does not apply to a Balancing Authority that is the only Balancing Authority in its Interconnection. These Balancing Authorities are solely responsible for providing reliable frequency control of their Interconnection. These Balancing Authorities are responsible for converting frequency error into a megawatt error to provide reliable frequency control, and the imposition of a minimum bias setting greater than the magnitude the Frequency Response Obligation may have the potential to cause control system hunting, and instability in the extreme.

The ERO, in coordination with the regions of each interconnection, will annually review Frequency Bias Setting data submitted by BAs. If an Interconnection's total minimum Frequency Bias Setting exceeds (in absolute value) the Interconnection's total natural Frequency Response by more (in absolute value) than 0.2 percentage points of peak load (expressed in MW/0.1Hz), the minimum Frequency Bias Setting for BAs within that Interconnection may be reduced (in absolute value) in the subsequent years FRS Form 1 based on the technical evaluation and consultation with the regions affected by 0.1 percentage point of peak load (expressed in MW/0.1Hz) to better match that Frequency Bias Setting and natural Frequency Response.

The ERO, in coordination with the regions of each Interconnection, will monitor the impact of the reduction of minimum frequency bias settings, if any, on frequency performance, control performance, and system reliability. If unexpected and undesirable impacts such as, but not limited to, sluggish post-contingency restoration of frequency to schedule or control performance problems occur, then the prior reduction in the minimum frequency bias settings may be reversed, and/or the prospective reduction based on the criterion stated above may not be implemented.

Interconnection Frequency Response Obligation Methodology

This procedure outlines the process the ERO is to use for determining the Interconnection Frequency Response Obligation (IFRO).

The following are the formulae that comprise the calculation of the IFROs.

$$DF_{Base} = F_{Start} - UFLS$$

$$DF_{CC} = DF_{Base} - CC_{Adj}$$

$$DF_{CBR} = \frac{DF_{CC}}{CB_R}$$

$$MDF = DF_{CBR} - BC'_{Adj}$$

$$ARCC = RCC - CLR$$

$$IFRO = \frac{ARCC}{10 * MDF}$$

Where:

- DF_{Base} is the base delta frequency.
- F_{Start} is the starting frequency determined by the statistical analysis.
- UFLS is the highest UFLS trip setpoint for the interconnection.
- CC_{Adj} is the adjustment for the differences between 1-second and sub-second Point C observations for frequency events. A positive value indicates that the sub-second C data is lower than the 1-second data.
- DF_{CC} is the delta frequency adjusted for the differences between 1-second and sub-second Point C observations for frequency events.
- CB_R is the statistically determined ratio of the Point C to Value B.
- DF_{CBR} is the delta frequency adjusted for the ratio of the Point C to Value B.
- BC'_{ADJ} is the statistically determined adjustment for the event nadir being below the Value B (Eastern Interconnection only) during primary frequency response withdrawal.
- MDF is the maximum allowable delta frequency.
- RCC is the resource contingency criteria.
- CLR is the credit for load resources.
- ARCC is the adjusted resource contingency criteria adjusted for the credit for load resources.
- IFRO is the interconnection frequency response obligation.

Introduction

This document provides background on the development, testing and implementation of BAL-003-1 - Frequency Response Standard (FRS).[1] The intent is to explain the rationale and considerations for the Requirements of this standard and their associated compliance information. The document also provides good practices and tips for Balancing Authorities ("BAs") with regard to Frequency Response.

In Order No. 693, the Federal Energy Regulatory Commission ("FERC" or the "Commission") directed additional changes to BAL-003.[2] This document explains how compliance with those directives are met by BAL-003-1.

The original Standards Authorization Request ("SAR"), finalized on June 30, 2007, assumed there was adequate Frequency Response in all the North American Interconnections. The goal of the SAR was to update the Standard to make the measurement process of frequency response more objective and to provide this objective data to Planners and Operators for improved modeling. The updated models will improve understanding of the trends in Frequency Response to determine if reliability limits are being approached. The Standard would also lay the process groundwork for a transition to a performance-based Standard if reliability limits are approached.

This document will be periodically updated by the FRS Drafting Team (FRSDT) until the Standard is approved. Once approved, this document will then be maintained and updated by the ERO and the NERC Resources Subcommittee to be used as a reference and training resource.

Background

This section discusses the different components of frequency control and the individual components of Primary Frequency Control also known as Frequency Response.

Frequency Control

Most system operators generally have a good understanding of frequency control and Bias Setting as outlined in the balancing standards and the references to them in the NERC Operating Manual. Frequency control can be divided into four overlapping windows of time as outlined below.

> **Primary Frequency Control (Frequency Response) –** Actions provided by the Interconnection to arrest and stabilize frequency in response to frequency deviations. Primary Control comes from automatic generator governor response (also known as speed

[1] Unless otherwise designated herein, all capitalized terms shall have the meaning set forth in the Glossary of Terms Used in NERC Reliability Standards, available here: http://www.nerc.com/files/Glossary_of_Terms.pdf.

[2] *Mandatory Reliability Standards for the Bulk-Power System*, Order No. 693, FERC Stats. & Regs. ¶ 31,242 at PP 368-375, *order on reh'g*, Order No. 693-A, 120 FERC ¶ 61,053 (2007).

regulation), load response (typically from motors), and other devices that provide an immediate response based on local (device-level) control systems.

Secondary Frequency Control – Actions provided by an individual BA or its Reserve Sharing Group to correct the resource – load unbalance that created the original frequency deviation, which will restore both Scheduled Frequency and Primary Frequency Response. Secondary Control comes from either manual or automated dispatch from a centralized control system.

Tertiary Frequency Control – Actions provided by Balancing Authorities on a balanced basis that are coordinated so there is a net zero effect on Area Control Error (ACE). Examples of Tertiary Control include dispatching generation to serve native load; economic dispatch; dispatching generation to affect Interchange; and re-dispatching generation. Tertiary Control actions are intended to replace Secondary Control Response by reconfiguring reserves.

Time Control includes small offsets to scheduled frequency to keep long term average frequency at 60 Hz.

Primary Frequency Control – Frequency Response

Primary Frequency Control, also known generally as **Frequency Response**, is the first stage of overall frequency control and is the response of resources and load to a locally sensed change in frequency in order to arrest that change in frequency. Frequency Response is automatic, not driven by any centralized system, and begins within seconds rather than minutes. Different resources, loads, and systems provide Frequency Response with different response times, based on current system conditions such as total resource/load and their respective mix.

The proposed NERC Glossary of Terms defines **Frequency Response** as:

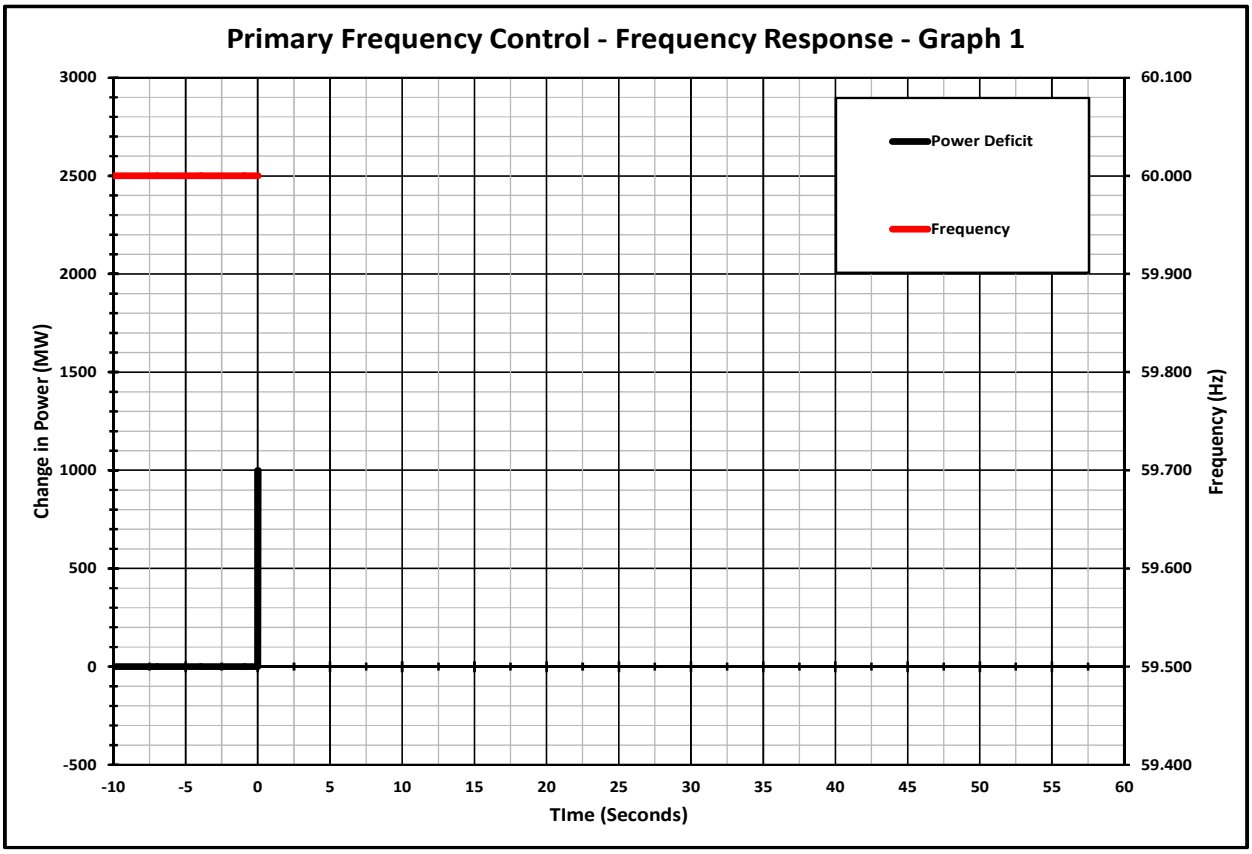
- (Equipment) The immediate and automatic reaction or response of power from a system or power from elements of the system to a change in locally sensed system frequency.
- (System) The sum of the change in demand, and the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 Hertz (MW/0.1 Hz).

As noted above, Frequency Response is the characteristic of load and generation within Balancing Authorities and Interconnections. It reacts or responds with changes in power to attempted changes in load-resource balance that result in changes to system frequency. Because the loss of a large generator is much more likely than a sudden loss of an equivalent amount of load, Frequency Response is typically discussed in the context of a loss of a large generator. Included within Frequency Response are many components of that response. Understanding Frequency Response and the FRS requires an understanding of each of these components and how they relate to each other.

Frequency Response Illustration

The following simple example is presented to illustrate the components of Frequency Response in graphical form. It includes a series of seven graphs that illustrate the various components of

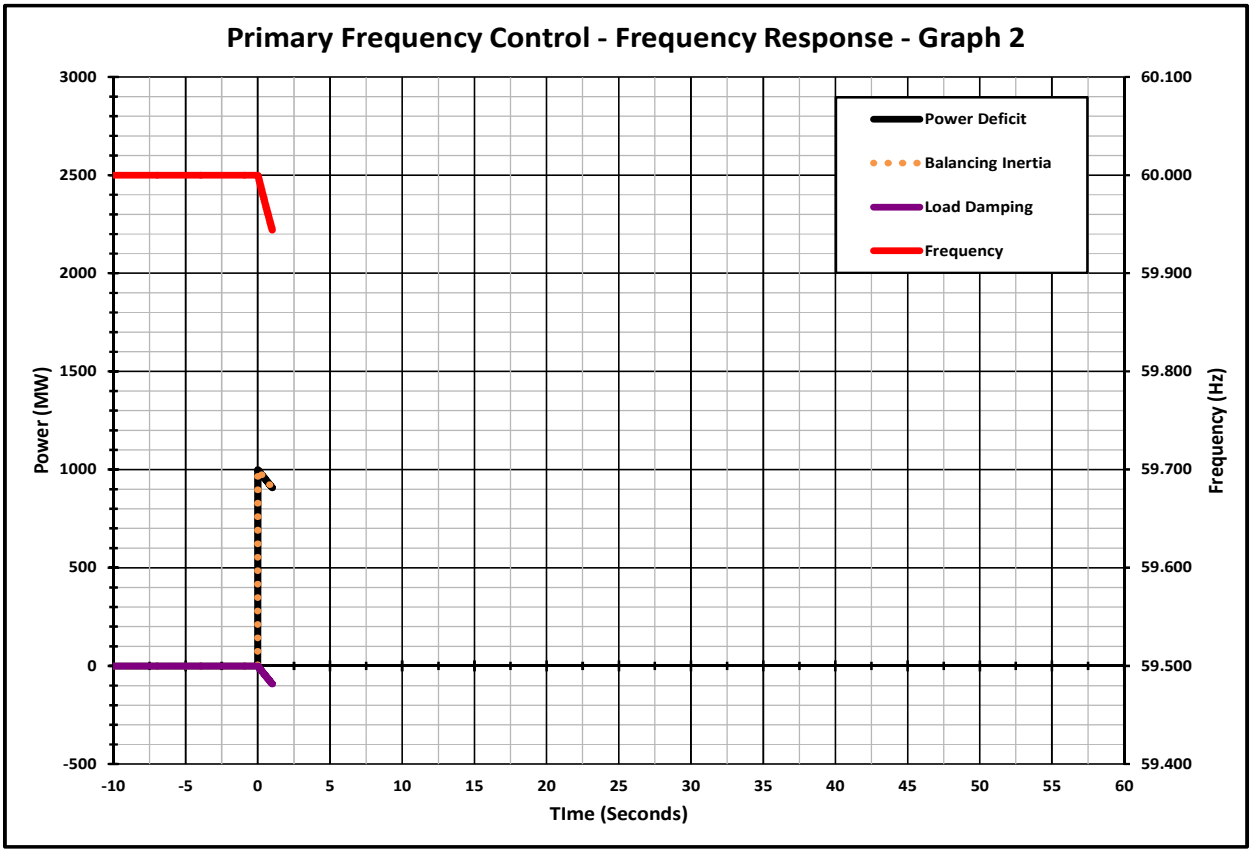
Frequency Response and a brief discussion of each describing how these components react to attempted changes in the load-resource balance and resulting changes in system frequency. The illustration is based on an assumed Disturbance event of the sudden loss of 1000 MW of generation. Although a large event is used to illustrate the response components, even small frequently occurring events will result in similar reactions or responses. The magnitude of the event only affects the shape of the curves on the graph; it does not obviate the need for Frequency Response.



The first graph, Primary Frequency Control – Frequency Response – Graph 1, presents a sudden loss of generation of 1000 MW. The components are presented relative to time as shown on the horizontal Time axis in seconds. This simplified example assumes a Disturbance event of the sudden loss of generation resulting from a breaker trip that instantaneously removes 1000 MW of generation from the interconnection. This sudden loss is illustrated by the power deficit line shown in black using the MW scale on the left. Interconnection frequency is illustrated by the frequency line shown in red using the Hertz scale on the right. Since the Scheduled Frequency is normally 60 Hz, it is assumed that this is the frequency when the Disturbance event occurs.

Even though the generation has tripped and power injected by the generator has been removed from the interconnection, the loads continue to use the same amount of power. The

"Law of Conservation of Energy"[3] requires that the 1000 MW must be supplied to the interconnection if energy balance is to be "conserved". This additional 1000 MW of power is produced by extracting kinetic energy that was stored in the rotating mass of all of the synchronized generators and motors on the interconnection – essentially using this equipment as a giant flywheel. The extracted energy supplies the "balancing inertia"[4] power required to maintain the power and energy balance on the interconnection. This balancing inertia power is produced by the generators' spinning inertial mass' resistance to the slowdown in speed of the rotating equipment on the interconnection that both provides the stored kinetic energy and reduces the frequency of the interconnection. This is illustrated in the second graph, Primary Frequency Control – Frequency Response – Graph 2, by the orange dots representing the balancing inertia power that exactly overlay and offset the power deficit.



As the frequency decreases, synchronized motors slow, as does the work they are providing, resulting in a decrease in load called "load damping." This load damping is the reason that the power deficit initially declines. Synchronously operated motors will contribute to load damping. Variable speed drives that are decoupled from the interconnection frequency do not

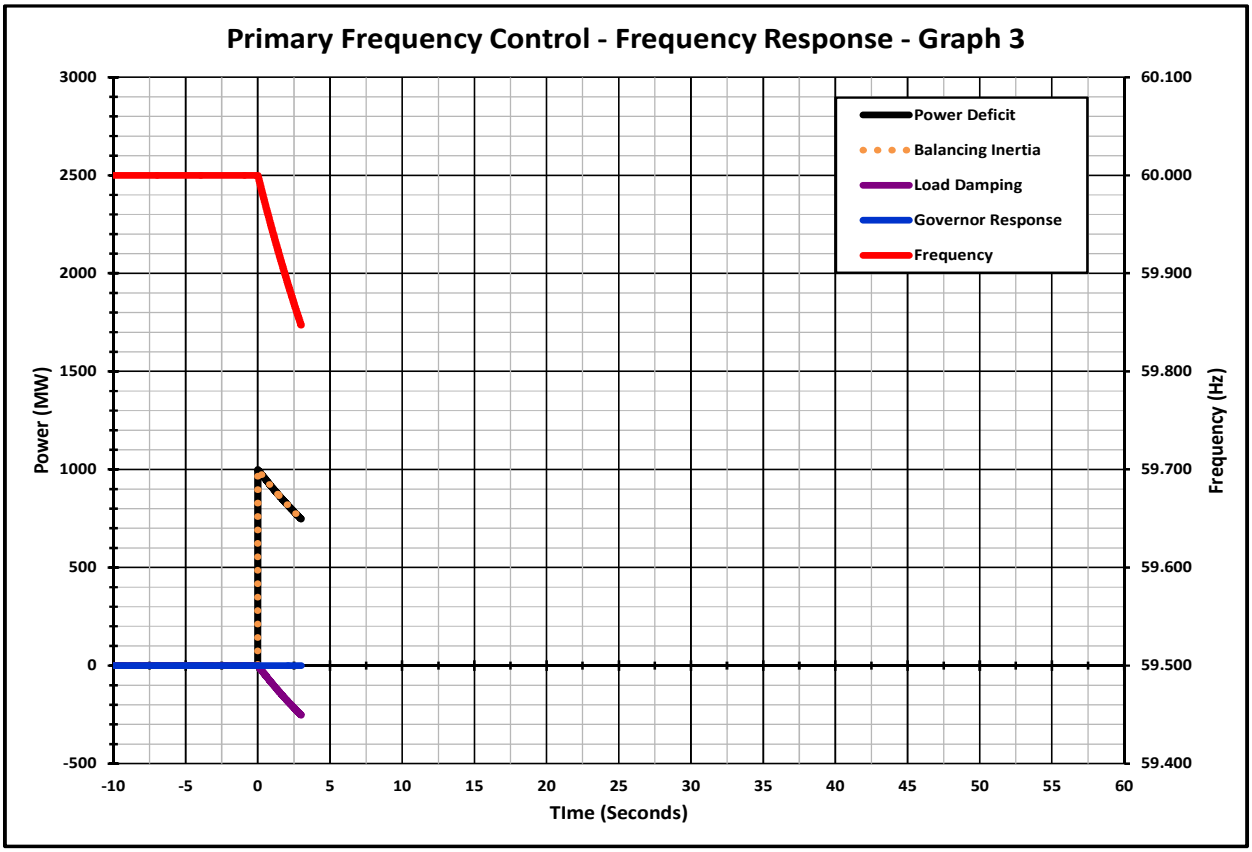
[3] The "Law of Conservation of Energy" is applied here in the form of power. If energy must be conserved, then power which is the first derivative of energy with respect to time, must also be conserved.

[4] The term "balancing Inertia" is coined here from the terms "inertial frequency response" and "balancing energy". Inertial frequency response is a common term used to describe the power supplied for this portion of the frequency response and balancing energy is a term used to describe the market energy supposedly purchased to restore energy balance.

contribute to load damping. In general, any load that does not change with interconnection frequency including resistive load will not contribute to load damping or Frequency Response.

It is important to note that the power deficit equals exactly the balancing inertia, indicating that there is no power or energy imbalance at any time during this process. What is normally considered as "balancing power or energy" is actually power or energy required to correct the frequency error from scheduled frequency. Any apparent power or energy imbalance is corrected instantaneously by the balancing inertia power and energy extracted from the interconnection. Thus the balancing function is really a frequency control function described as a balancing function because ACE is calculated in MWs instead of Hertz, frequency error.

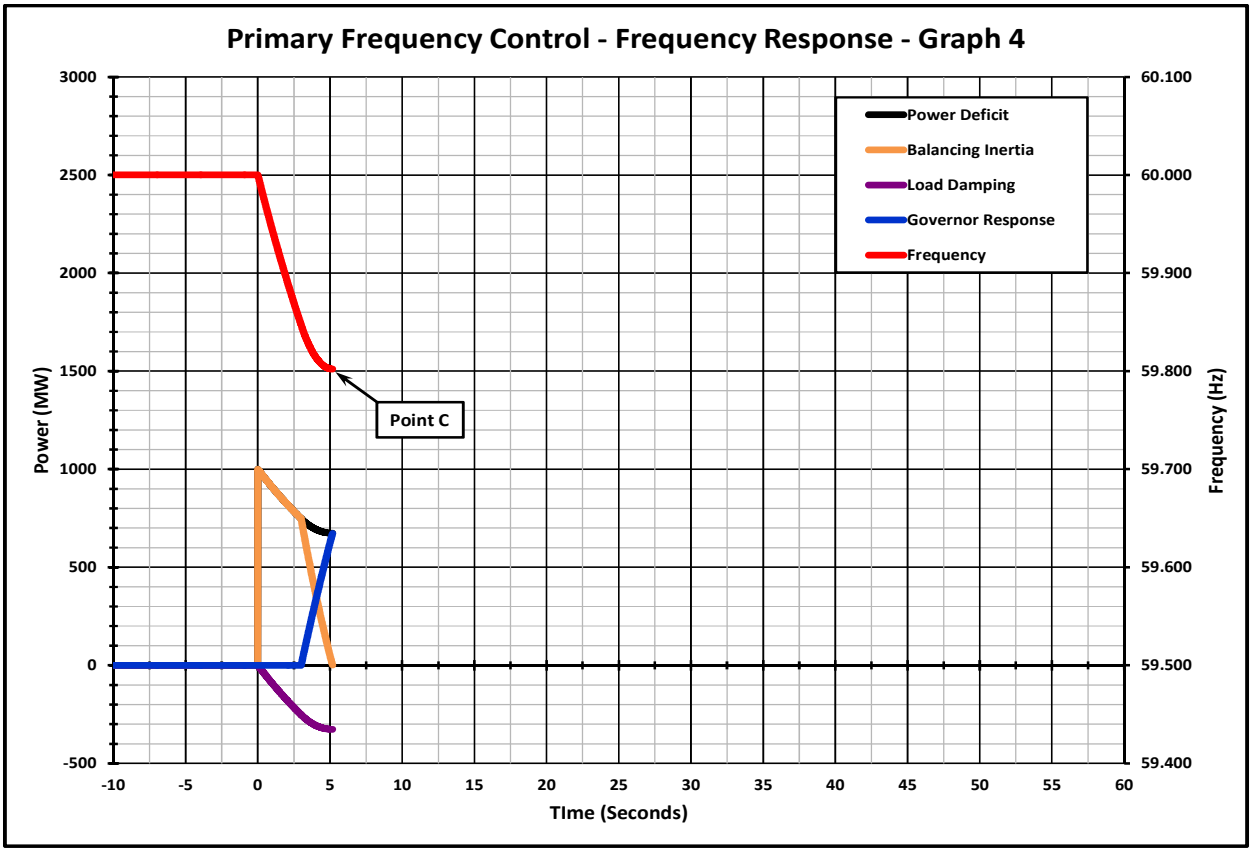
During the initial seconds of the Disturbance event, the governors have yet to respond to the frequency decline. This is illustrated with the Blue line on the third graph, Primary Frequency Control – Frequency Response – Graph 3, showing Governor Response. This time delay results from the time that it takes the controller to adjust the equipment and the time it takes the mass to flow from the source of the energy (main steam control valve for steam turbines, the combustor for gas turbines, or the gate valve for hydro turbines) to the turbine-generator blades where the power is converted to electrical energy.



Note that the frequency continues to decline due to the ongoing extraction by balancing inertia power of energy from the rotating turbine-generators and synchronous motors on the interconnection. The reduction in load also continues as the effect of load damping continues

to reduce the load while frequency declines. During this time delay (before the governor response begins) the balancing inertia limits the rate of change of frequency.

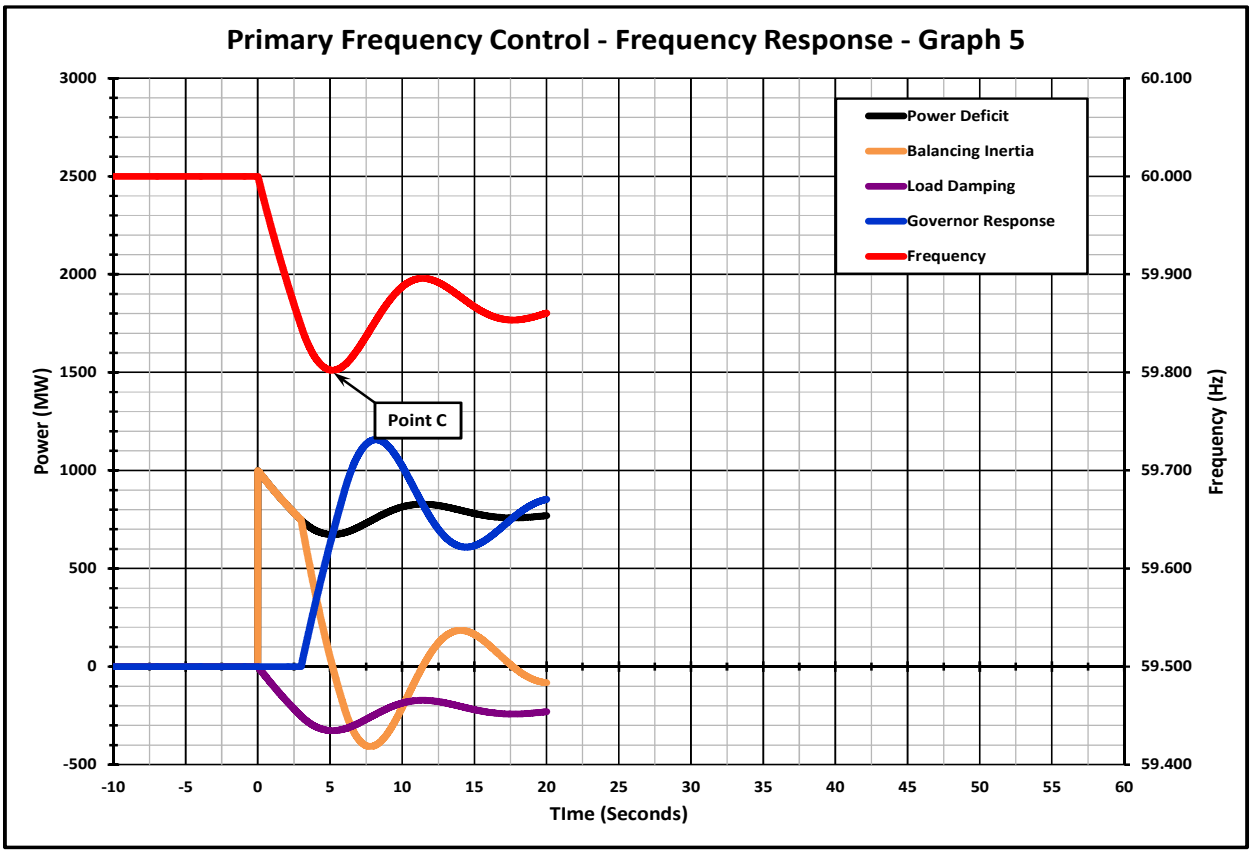
After a short time delay, the governor response begins to increase rapidly in response to the initial rapid decline in frequency, as illustrated on the fourth graph, Primary Frequency Control – Frequency Response – Graph 4. Governor response exactly offsets the power deficit at the point in time that the frequency decline is arrested. At this point in time, the balancing inertia has provided its contribution to reliability and its power contribution is reduced to zero as it is replaced by the governor response. If the time delay associated with the delivery of governor response is reduced, the amount of balancing inertia required to limit the change in frequency by the Disturbance event can also be reduced. This supports the conclusion that balancing inertia is required to manage the time delays associated with the delivery of Frequency Response. Not only is the rapid delivery of Frequency Response important, but the shortening of the time delay associated with its delivery is also important. Therefore, two important components of Frequency Response are 1) how long the time delay is before the initial delivery of response begins; and 2) how much of the response is delivered before the frequency change is arrested.



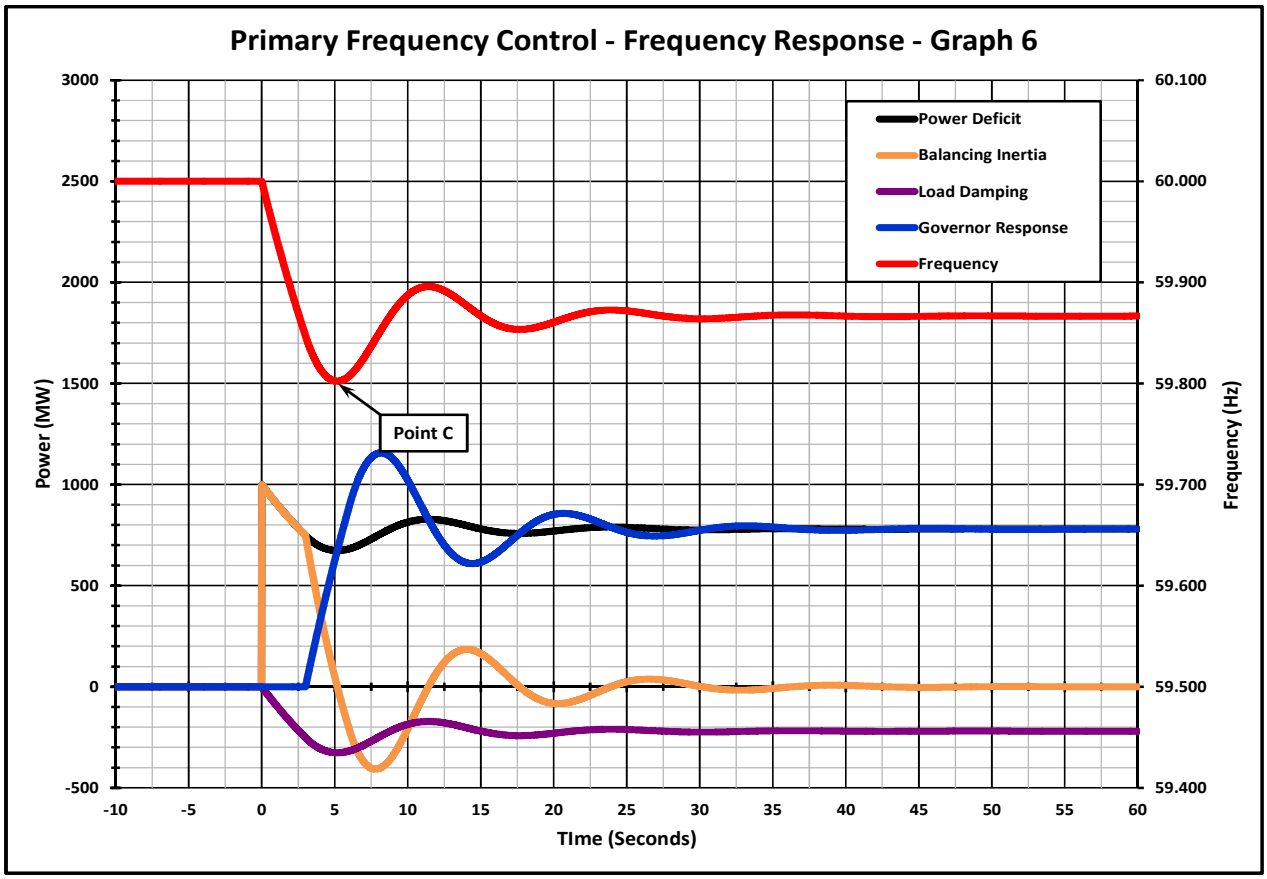
This point, at which the frequency is first arrested, is defined as "Point C" and Frequency Response calculated at this point is called the "**arrested frequency response**." The arrested frequency is normally the minimum (maximum for load loss events) frequency that will be

experienced during a Disturbance event. From a reliability perspective, this minimum frequency is the frequency that is of concern. Adequate reliability requires that frequency at the time frequency is arrested remain above the under-frequency relay settings so as not to trip these relays and the firm load interrupted by them. Frequency Response delivered after frequency is arrested at this minimum level provides less reliability value than Frequency Response delivered before Point C, but greater value than Secondary Frequency Control power and energy which is delivered minutes later.

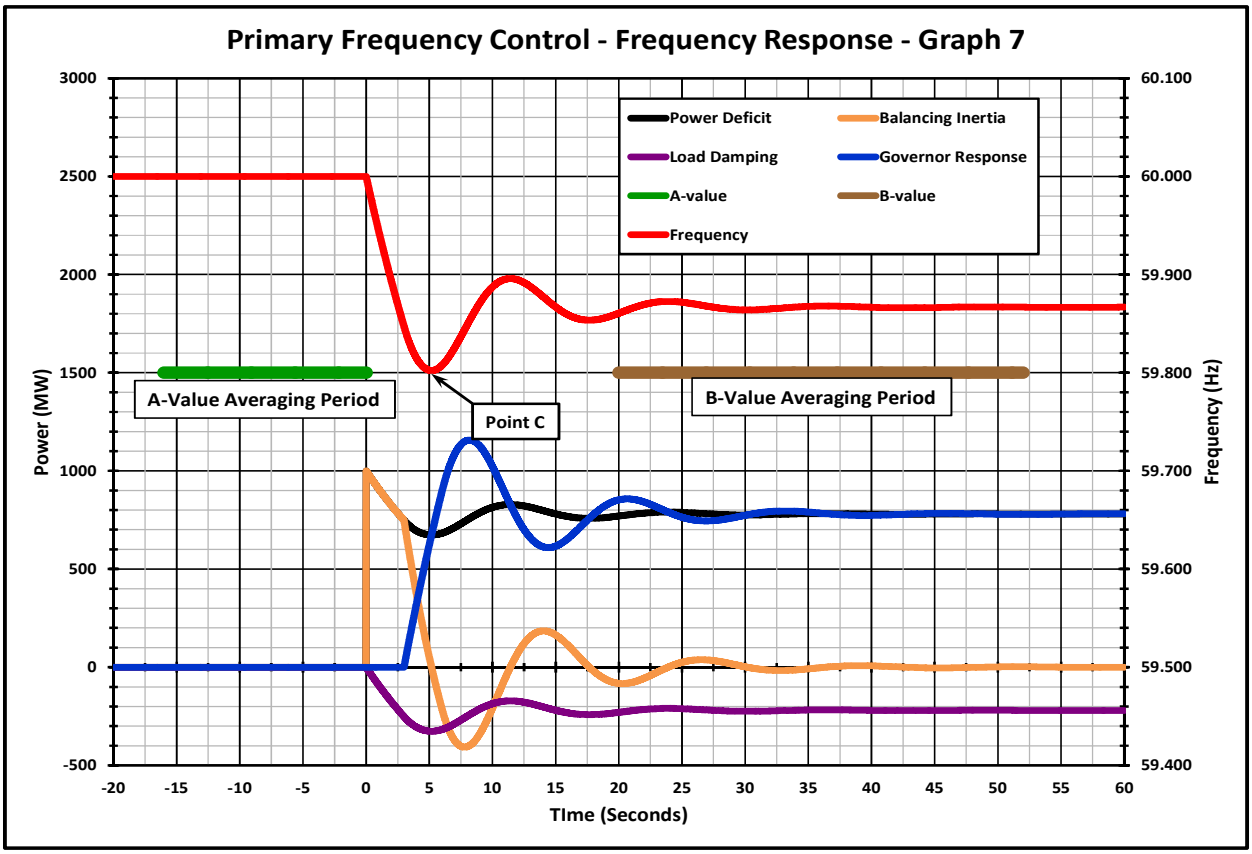
Once the frequency decline is arrested, the governors continue to respond because of the time delay associated with their Governor Response. This results in the frequency partially recovering from the minimum arrested value and results in an oscillating transient that follows the minimum frequency (arrested frequency) until power flows and frequency settle during the transient period that ends roughly 20 seconds after the Disturbance event. This post-disturbance transient period is included on the fifth illustrative graph, Primary Frequency Control – Frequency Response – Graph 5.



The total Disturbance event illustration is presented on the sixth graph, Primary Frequency Control – Frequency Response – Graph 6. Frequency and power contributions stabilize at the end of the transient period. Frequency Response calculated from data measured during this settled period is called the "Settled Frequency Response." The Settled Frequency Response is the best measure to use as an estimator for the "Frequency Bias Setting" discussed later.



The final Disturbance event illustration is presented on the seventh graph, Primary Frequency Control – Frequency Response – Graph 7. This graph shows the averaging periods used to estimate the pre-disturbance A-Value averaging period and the post-disturbance B-Value averaging period used to calculate the settled frequency response. A discussion of the measurement of Frequency Response immediately follows these graphs. That discussion includes consideration of the factors that affect the methods chosen to measure Frequency Response for implementation in a reliability standard.



Frequency Response Measurement (FRM)

The classic Frequency Response points A, C, and B, shown below in Fig. 1 Frequency Response Characteristic, are used for measurement as found in the Frequency Response Characteristic Survey Training Document within the NERC operating manual, found at http://www.nerc.com/files/opman_7-1-11.pdf. This traditional Frequency Response Measure has recently been more specifically termed "**settled frequency response**." This term has been used because it provides the best Frequency Response Measure to estimate the Frequency Bias Setting in Tie-line Bias Control based Automatic Generation Control Systems. However, the industry has recognized that there is considerable variability in measurement resulting from the selection of Point A and Point B in the traditional measure making the traditional measurement method unsuitable as the basis for an enforceable reliability standard in a real world setting of multiple Balancing Authority interconnections.

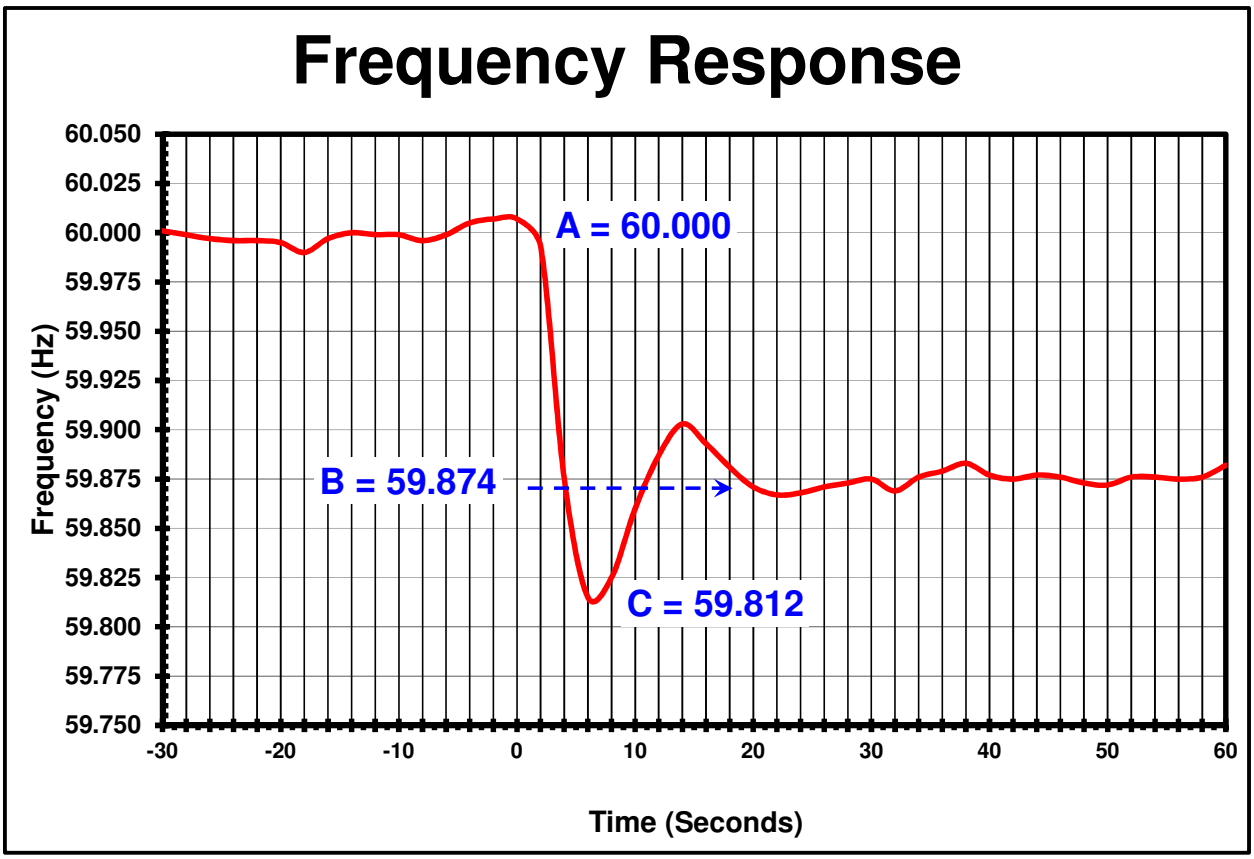


Figure 1. Frequency Response Characteristic

By contrast, measuring an Interconnection's settled frequency response is straightforward and fairly accurate. All that's needed to make the calculation is to know the size of a given contingency (MW), divide this value by the change in frequency and multiply the results by 10 since frequency response is expressed in MW/0.1Hz.

Measuring a BA's frequency response is more challenging. Prior to BAL-003-1, NERC's *Frequency Response Characteristic Survey Training Document* provided guidance to calculate Frequency Response. In short, it told the reader to identify the BA's interchange values "immediately before" and "immediately after" the Disturbance event and use the difference to calculate the MWs the BA deployed for the event. There are two challenges with this approach:

- Two people looking at the same data would come up with different values when assessing which exact points were immediately before and after the event.
- In practice, the actual response provided by the BA can change significantly in the window of time between point B and when secondary and tertiary control can assist in recovery.

Therefore, the measurement of settled frequency response has been standardized in a number of ways to limit the variability in measurement resulting from the poorly specified selection of Point A and Point B. It should be noted that t-0 has been defined as the first scan value that

shows a deviation in frequency of some significance, usually approaching about 10 mHz. The goal is such that the first scan prior to t-0 was unaffected by the deviation and appropriate for one of the averaging points.

- The A-value averaging period of approximately the previous 16 seconds prior to t-0 was selected to allow for an averaging of at least 2 scans for entities utilizing 6 second scan rates. (All time average period references in this document are for 2 second scan rates unless noted otherwise.)
- The B-value averaging period of approximately (t+20 to t+52 seconds) was selected to attempt to obtain the average of the data after primary frequency response was deployed and the transient completed(settled), but before significance influence of secondary control. Multiple periods were considered for averaging the B-value:
    - 12 to 24 sec
    - 18 to 30 sec
    - 20 to 40 sec
    - 18 to 52 sec
    - 20 to 52 sec

  It is necessary for all BAs from an interconnection to use the same averaging periods to provide consistent results. In addition, the SDT decided that until more experience is gained, it is also desirable for all interconnections to use the same averaging periods to allow comparison between interconnections.

The methods presented in this document only address the values required to calculate the frequency response associated with the frequency change between the initial frequency, A-Value, and the settling frequency, B-Value. No reasonable or consistent calculations can be made relating to the arresting frequency, C-Value, using Energy Management System (EMS) scan rate data as long as 6-seconds or tie-line flow values associated with the minimum value of the frequency response characteristic (C-value) as measured at the BA level.

Both the calculation of the frequency at Point A and the frequency at Point B began with the assumption that a 6-second scan rate was the source of the data. Once the averaging periods for a 6-second scan rate were selected, the averaging periods for the other scan rates were selected to provide as much consistency as possible between BAs with different scan rates.

The Frequency at Point A was initially defined as the average of the two scans immediately prior to the frequency event. All other averaging periods were selected to be as consistent as possible with this 12 second average scan from the 6-second scan rate method. In addition, the "**actual net interchange immediately before Disturbance**" is defined as the average of the same scans as used for the Point A frequency average.

The Frequency at Point B was then selected to be an average as long as the average of 6-second scan data as possible that would not begin until most of the hydro governor response had been delivered and would end before significant Automatic Generation Control (AGC) recovery response had been initiated as indicated by a consistent frequency restoration slope. The "**actual net interchange immediately after Disturbance**" is defined as the average of the same scans as used for the Point B frequency average.

B Averaging Period Selection:

Experience from the Electric Reliability Council of Texas ("ERCOT") and the field trail on other interconnections indicated that the 12 to 24 second and 18 to 30 second averaging periods were not suitable because they did not provide the consistency in results that the other averaging periods provided, and that the remaining measuring periods do not provide significantly different results from each other. The team believed that this was observed because the transients were not complete in all of the samples using these averaging periods.

The 18 to 52 second and 20 to 52 second averaging periods were compared to each other, with the 20 to 52 second period providing more consistent values, believed to result from the incomplete transient in some of the 18 to 52 second samples.

This left a choice between the 20 to 40 second and the 20 to 52 second averaging periods. The team recognized that there would be more AGC response in the 20 to 52 second period, but the team also recognized that the 20 to 52 second period would provide a better measure of squelched response from outer loop control action. The 20 to 52 second period was selected because it would indicate squelched response from outer-loop control and provide incentive to reduce response withdrawal. The final selections for the data averaging periods used in FRS Form 1 are shown in the table below.

Definitions of Frequency Values for Frequency Response Calculation

Scan Rate	T 0 Scan	A Value (average)	B Value (average)
6-Seconds	Identify first significant change in frequency as the T 0 scan	Average of T-1 through T-2 scans	Average of T+4 through T+8 scans
5-Seconds		Average of T-1 through T-2 scans	Average of T+5 through T+10 scans
4-Seconds		Average of T-1 through T-3 scans	Average of T+6 through T+12 scans
3-Seconds		Average of T-1 through T-5 scans	Average of T+7 through T+17 scans
2-Seconds		Average of T-1 through T-8 scans	Average of T+10 through T+26 scans

Consistent measurement of Primary Frequency Response is achievable for a selected number of events and can produce representative frequency response values, provided an appropriate sample size is used in the analysis. Available research investigating the minimum sample size to provide consistent measurements of Frequency Response has shown that a minimum sample size of 20 events should be adequate.

Measurement of Primary Frequency Response on an individual resource or load basis requires analysis of energy amounts that are often small and difficult to measure using current methods. In addition, the number of an interconnection's resources and loads providing their response could be problematic when compiling results for multiple events.

Measurement of Primary Frequency Response on an interconnection (System) basis is straight forward provided that an accurate frequency metering source is available and the magnitude of the resource/load imbalance is known in MWs.

Measurement on a Balancing Authority basis can be a challenge, since the determination of change in MWs is determined by the change in the individual BA's metered tie lines. Summation of tie lines is accomplished by summing the results of values obtained by the digital scanning of meters at intervals up to six seconds, resulting in a non-coincidental summing of values. Until the technology to GPS time stamp tie line values at the meter and the summing of those values for coincidental times is in use throughout the industry, it is necessary to use averaging of values described above to obtain consistent results.

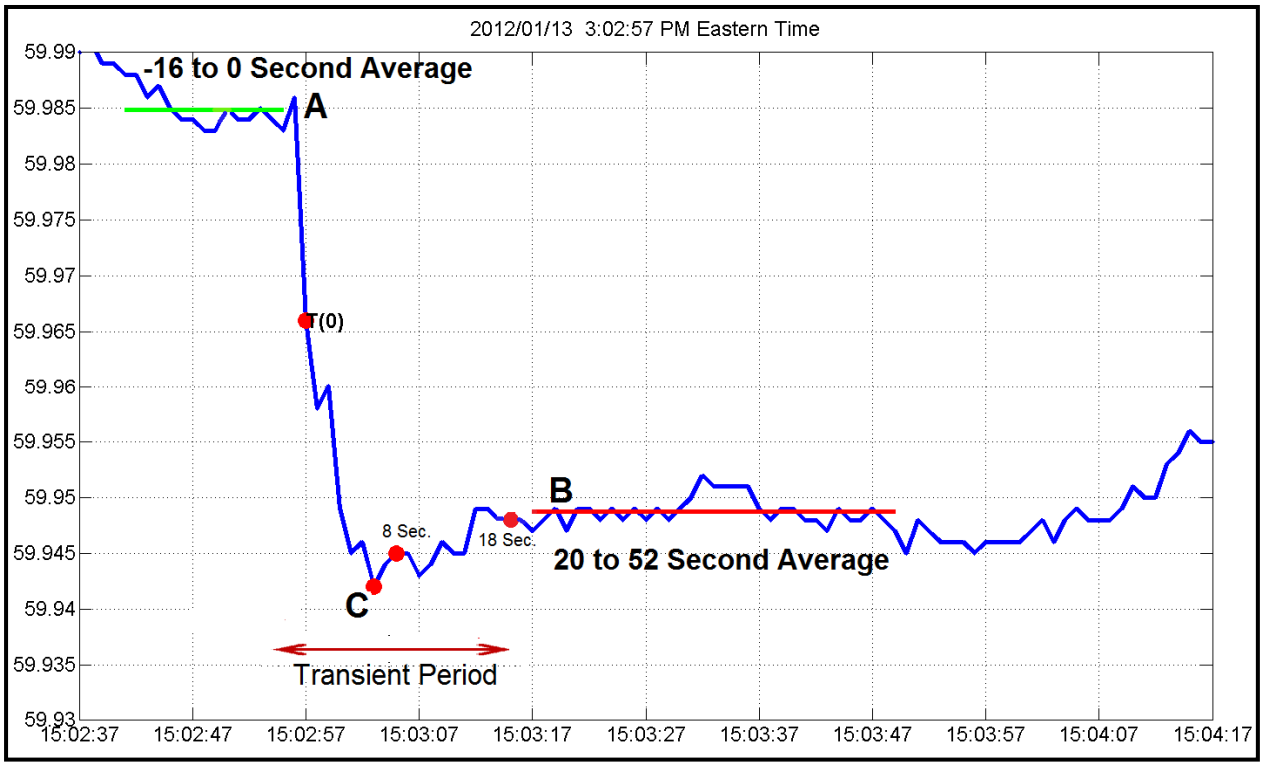

Figure 2. Frequency Response Measurement

The standardized measure is shown graphically in Fig. 2 Frequency Response Measurement with the averaging periods shown by the solid green and red lines on the graph. Since FERC directed a performance obligation for BAL-003-1, it is important to be more objective in the measurement process. The standardized calculation is available on FRS Form 2 for EMS scan rates of 2, 3, 4, 5, and 6 seconds at http://www.nerc.com/filez/standards/Frequency_Response.html.

Arrested Frequency Response

There is another measure of Frequency Response that is of interest when developing a Frequency Response estimate that not only will be used for estimating the Frequency Bias Setting, but will also be used to assure reliability by operating in a manner that will bound interconnection frequency and prevent the operation of Under-frequency Relays. This Frequency Response Measure has recently been named "**arrested frequency response.**" This Frequency Response is significantly affected by the inertial Frequency Response, the governor Frequency Response and the time delays associated with the delivery of governor Frequency

Response. It is calculated by using the change in frequency between the initial frequency, A, and the maximum frequency change during the event, C, instead of using the change between A and B. Arrested Frequency Response is the correct response for determining the minimum Frequency Response related to under-frequency relay operation and the support of interconnection reliability. This is because it can be used to provide a direct estimate of the maximum frequency deviation an interconnection will experience for an initial frequency and a given size event in MW. Unfortunately, arrested frequency response cannot currently be measured using the existing EMS-based measurement infrastructure. This limitation exists because the scan rates currently used in industry EMSs are incapable of measuring the net actual interchange at the same instant that the maximum frequency deviation is reached. Fortunately, the ratio of arrested frequency response and settled frequency response tends to be stable on an interconnection. This allows the settled frequency response value to be used as a surrogate for the arrested frequency response and implement a reasonable measure upon which to base a standard. One consequence of using the settled frequency response as a surrogate for the arrested frequency response is the inclusion of a large reliability margin in Interconnection Frequency Response Obligation to allow for the difference between the settled frequency response as measured and the arrested frequency response that indicates reliability.

As measurement infrastructure improves one might expect the Frequency Response Obligation to transition to a measurement based directly on the arrested frequency response while the Frequency Bias Setting will continue to be based on the settled frequency response. However, at this time, the measurement devices and methods in use do not support the necessary level of accuracy to estimate arrested frequency response contribution for an individual Balancing Authority.

Frequency Response Definition and Examples

Limitations of the measurement infrastructure determine the measurement methods recommended in this standard. The measurement limitations provide opportunities to improve the Frequency Response as measured in the standard without contributing to an improvement in Frequency Response that contributes to reliability. These definitions and examples provide a basis for determining which contributions to Frequency Response contribute the most to improved reliability. They also provide the basis for determining on a case by case basis whether the individual contributors to the Frequency Response Measure are also contributing to reliability.

General Frequency Response Characteristics

In the simplest case Frequency Response includes any automatic response to changes in local frequency. If that response works to decrease that change in frequency, it is beneficial to reliability. If that response works to increase that change in frequency, it is detrimental to reliability. However, this definition does not address the relative value of one response as compared to other responses that may be provided in a specific case.

There are numerous characteristics associated with the Frequency Response that affect the reliability value and economic value of the response. These characteristics include:

1. **Inertial** – the response is inertial or approximates inertial response

Inertial response provides power without delay that is proportional to the frequency and the change in frequency. Therefore, power provided by electronic control as synthetic Inertial response must be proportional to the frequency and change in frequency and be provided without a time delay.

2. **Immediate** – no unnecessary intentional time delays or reduction in the rate of response delivery
    a. time delay before the beginning of the response
    Turbines that convert heat or kinetic energy have time delays related to the time delay from the time that the control valves are moved to initiate the change in power and the time that the power is delivered to the generator. These times are usually associated with the time it takes a change in mass flow to travel from the control valve to the first blades of the turbine in the turbine generator.

    b. reduction in the rate of response delivery
    There are natural delays associated with the rate of response delivery that are related to the mass flow travel from the first turbine blades to the last turbine blades. In addition, some turbines have intentional delays designed into the control system to slow the rate of change in the delivery of the kinetic energy or fuel to the turbine to prevent the turbine or other equipment from being damaged, hydro turbines, or to prevent the turbine from tripping due to excessive rate of change, gas turbines.

3. **Proportional** – the amount of the total response is proportional to the frequency error
    a. No Deadband – the response is proportional across the entire frequency range
    b. Deadband – the response is only proportional outside of a defined deadband

4. **Bi-directional** – the response occurs to both increases and decreases in frequency

5. **Continuous** – there are no discontinuities in the delivery of the response (no step changes)

6. **Sustained** – the response is sustained until frequency is returned to schedule

Frequency Response Reliability Value

This section contains a more detailed discussion of the various characteristics of Frequency Response listed in the previous section. It also provides an indication of the relative value of these characteristics with respect to their contribution to reliability. Finally, it includes some examples of the described responses.

Inertial Response is provided from the stored energy in the rotating mass of the turbine-generators and synchronous motors on the interconnection. It limits the rate of change of frequency until sufficient Frequency Response can be supplied to arrest the change in frequency. Its reliability value increases as the time delay associated with the delivery of other Frequency Response on the interconnection increases. If those time delays are minimal, then the value of inertial response is low. If all time delays associated with the Frequency Response could be eliminated, then inertial response would have little value.

The reliability value of Inertial Response is the greatest on small interconnections because the size of the Disturbance events is larger relative to the inertia of the interconnection. Electronic controls have been developed to provide synthetic inertial response from the stored energy in asynchronous generators to supplement the natural inertial response. Some Type III & IV Wind Turbines have this capability. In addition, electronically controlled SCRs have been developed that can store energy in the electrical system and release this stored energy to supply synthetic inertial response when required.

Immediate Response is provided by load damping and because the time delays associated with its delivery are very short (related to the speed of electrical signal in the electrical system); load damping requires very little inertial response to limit arrested frequency effectively. Synthetic immediate response can also be supplied from loads because in many cases, there is no mass flow time delay associated with the load process providing the power and energy reduction. Therefore, loads can provide an immediate response with a higher reliability value than generators with time delays required by the physics of the turbine-generator.

Governor response has time delays associated with its delivery. Governor response provided with shorter time delays has a higher reliability value because those shorter time delays require less inertial response to arrest frequency. Governor response is provided by the turbine-generators on the interconnection. Time delays associated with governor response vary depending on the type of turbine-generator providing the response.

The longest time delays are usually associated with high head hydro turbine-generators that require long times from the governor action until the additional mass flow through the turbine. These units may also have the longest delivery time associated with the full delivery of response because of the timing designed into the governor response.[5]

Intermediate time delays are usually associated with steam turbine-generators. The response begins when the steam control valves are adjusted and the steam mass flows from the valves to the first high pressure turbine blades. The delivery times associated with the full delivery of response may require the steam to flow through high, intermediate and low pressure turbines including reheat flows before full power is delivered. These times are shorter than those of the hydro turbine-generators in general, but not as fast as the times associated with gas turbines.[6]

Gas turbines typically have the shortest time delays, because control is provided by injecting more or less fuel into the turbine combustor and adjusting the air control dampers. These control changes can be initiated rapidly and the mass flow has the shortest path to the turbine

[5] Interconnected Power System Response to Generation Governing: Present Practice and Outstanding Concerns – Final Report, IEEE, May 2007, pp. 1-6 – 1-9.

[6] Interconnected Power System Response to Generation Governing: Present Practice and Outstanding Concerns – Final Report, IEEE, May 2007, pp. 1-4 – 1-6.

blades. There may be timing limitations related to the rate of change in output of the gas turbine-generator to maintain flame stability in some cases slowing the rate of change.[7]

Synthetic Governor Response can be supplied by certain loads and storage systems. The immediacy of the response is normally limited only by the electronic controls used to activate the desired response. Synthetic response, when it can be supplied immediately without significant time delay, has a higher reliability value because it requires less inertial response to achieve smaller arrested frequency deviations.

Proportional Response indicates that the response provided is proportional in magnitude to the frequency error. Response deadbands cause a non-proportional response and reduce the value of the response with respect to reliability. Contrary to general consensus, deadbands do not reduce the amount of Frequency Response that must be provided, they only transfer the responsibility for providing that Frequency Response from one source on the interconnection to another. For a given response, the response with the smaller deadband has the greater reliability value. Therefore, deadbands should be set to the smallest value that supports overall reliable operation including the reliable operation of the generator.

Electronic controls have also been developed to provide synthetic governor response. When these controls are applied to certain loads or stored energy systems, they can be programmed to provide synthetic governor response similar to the proportional response of a turbine-generator governor. Governor response in generators is limited to a small percentage of the output of the generating unit, while synthetic governor response could be applied to much larger percentages of loads or storage devices providing such response.

Load damping provides a proportional response.

Continuous Response is response that has no discontinuous (step) changes in the frequency versus response curve. Step changes (Non-continuous Response) in the Governor Response curve can lead to frequency instabilities at frequencies near the changes. The ERCOT Interconnection observed this and has since prohibited the use of governor response characteristics incorporating step responses.

Step responses also occur with the implementation of load interruption using under-frequency or over-frequency relays.

Bi-directional Response is response that occurs in both directions, when the frequency is increasing and when the frequency is decreasing. A uni-directional response is a response that only occurs once when frequency is decreasing or when frequency is increasing.

Inertial response, governor response and load damping are all bi-directional responses. Certain loads are capable of providing proportional bi-directional response while others are only capable of providing non-proportional bi-directional response.

[7] Interconnected Power System Response to Generation Governing: Present Practice and Outstanding Concerns – Final Report, IEEE, May 2007, pp. 1-16 – 1-19.

The ERCOT Load Resource program is a uni-directional response program. Loads are only tripped when frequency declines below a given set-point. When frequency is restored above that set-point, the loads must be manually reconnected. As a consequence, the Frequency Response only occurs once with declining frequency and does not oppose the increase in frequency after the initial decline. If there should be a frequency oscillation, the uni-directional response will not contribute to the opposition of a second frequency decline across the set-point during an oscillation event. Once a uni-directional response has occurred, it is unavailable for a second decline before reset.

Step or proportional responses implemented bi-directionally can lead to frequency instability when there is less continuous frequency response than the magnitude of the change in continuous response between the trip and reset frequencies in step, or the proportional response rate of change is greater than the underlying continuous response. A step bi-directional response will have the load reconnected as frequency recovers from the event thus opposing the increase in frequency during recovery, and also resetting the load response for the next frequency decline automatically. Bi-directional response obviously has a greater reliability value than uni-directional response.

Sustained Response is provided at its full value until frequency is restored to its scheduled value. On today's interconnections, few frequency responses are fully sustained until frequency has been restored to its scheduled value. On steam based turbine-generators, the steam pressure may drop after a time as the result of the additional steam flow from governor action. However, in general this has not been a problem because most responses are incomplete at the time that frequency has been initially arrested and the additional response has generally been sufficient to make up for more than the these unpreventable reductions in response. However, the intentional withdrawal of response before frequency has been restored to schedule can cause a decline in frequency beyond that which would be otherwise expected. This intentional withdrawal of response is highly detrimental to reliability. Therefore, it can be concluded in general that sustained response has a higher reliability value than un-sustained response.

On an interconnection, the withdrawal of response due to the loss of steam pressure on the steam units may be offset by the slower response of hydro turbine-generators. In these cases, the reliability of the combined response provides a greater reliability value than the individual response of each type. The steam turbine-generators provide a fast response that may be reduced, while the hydro turbine-generators provide a slower response, contributing less to the arresting response, offsetting any reduction by the steam turbine-generators to assure a sustained response.

Sustained Response must also be considered for any resource that has a limited duration associated with its response. The amount of stored energy available from a resource may limit its ability to sustain response for a duration of time necessary to support reliability.

Frequency Response Cost Factors

In every system of exchange there are two sides; the supply side and the demand side. The supply side provides the services used by the demand side. In the case of Frequency Response,

the supply side includes all providers of Frequency Response and the demand side includes all participants that create the need for Frequency Response.

Frequency Response Costs – Supply Side

There are a number of factors that affect the cost of providing Frequency Response from resources. Since there is a cost associated with those factors, some method of appropriate compensation could be made available to those resources providing Frequency Response. Without compensation, providers of Frequency Response will be put in the position of incurring additional cost that can be avoided only by reducing or eliminating the response they provide. These costs are incurred independently of whether provided for in a formal Regional Transmission Organization/Independent System Operator (RTO/ISO) market or in a traditional BA subject to the FERC pro-forma tariffs.

It is the responsibility of the BA or the RTO/ISO to acquire the necessary amount of Frequency Response to support reliability in the most cost effective manner. This function is performed best when the suppliers are evaluated based on the value of the Frequency Response they provide and compensated appropriately for that Frequency Response. Suppliers provide Frequency Response when they are assured that they will receive fair compensation. Before considering how to perform this evaluation and compensation, the costs associated with providing Frequency Response should be understood and evaluated with respect to the level of reliability they offer.

Some cost factors that have been identified for providing Frequency Response include:

1. **Capacity Opportunity Cost** – the costs, including opportunity costs, associated with reserving capacity to provide Frequency Response. These costs are usually associated with the alternative use of the same capacity to provide energy or other ancillary services. There may also be capacity opportunity costs associated with the loss in average capacity by a load providing Frequency Response.
2. **Fuel Cost** – The cost of fuel used to provide the Frequency Response. The costs for fuel to provide Frequency Response can result in energy costs significantly different from the system marginal energy cost, both higher and lower. This is the case when Frequency Response is provided by resources that are not at the system marginal cost.
3. **Energy Efficiency Penalty Costs** – the costs associated with the loss in efficiency when the resource is operated in a mode that supports the delivery of Frequency Response. This cost is usually in the form of additional fuel use to provide the same amount of energy. An example is the difference between operating a steam turbine in valve control mode with an active governor and sliding pressure mode with valves wide open and no active governor control except for over-speed. This cost is incurred for all of the energy provided by the resource, not just the energy provided for Frequency Response. There may be additional energy costs associated with a load providing Frequency Response from loss in efficiency of their process when load is reduced.
4. **Capacity Efficiency Penalty Costs** – the costs associated with any reduction in capacity resulting from the loss of capacity associated with the loss in energy efficiency. When efficiency is lost, capacity may be lost at the same time because of limitations in the amount of input energy that can be provided to the resource.

5. **Maintenance Costs** – the operation of the resource in a manner necessary to provide Frequency Response may result in increases in the maintenance costs associated with the resource.
6. **Emissions Costs** – the additional costs incurred to manage any additional emissions that result when the resource is providing Frequency Response or stands ready to provide Frequency Response.

A good contract for the acquisition of Frequency Response from a resource will provide appropriate compensation to the resource for all of the costs the resource incurs to provide Frequency Response. It will also provide a method to evaluate the least cost mix of resources necessary to provide the minimum required Frequency Response for maintaining reliability. Finally, it will provide the least complex method of evaluation considering the complexity and efficiency of the acquisition process.

Frequency Response Costs – Demand Side

Not only are there costs associated with acquiring Frequency Response from the supplying resources, there are costs associated with the amount of Frequency Response that must be acquired and influenced by those participants that create the need for Frequency Response. If the costs of acquiring Frequency Response from the supply resources can be assigned to those parties that create the need for Frequency Response, there is the promise that the amount of Frequency Response required to maintain reliability can be minimized. The considerations are the same as those that are driving the development of "real time pricing" and "dynamic pricing". If the costs are passed on to those contributing to the need for Frequency Response, incentives are created to reduce the need for Frequency Response making interconnection operations less expensive and more reliable. The problem is to balance both cost and complexity against reliability on both the supply side and the demand side.

Rationale by Requirement

Requirement 1

R1. Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or Balancing Authority that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation.

Background and Rationale

R1 is intended to meet the following primary objectives:

- Determine whether a Balancing Authority (BA) has sufficient Frequency Response for reliable operations.
- Provide the feeder information needed to calculate CPS limits and Frequency Bias Settings.

Primary Objective

With regard to the first objective, FRS Form 1 and the process in Attachment A provide the method for determining the Interconnections' necessary amount of Frequency Response and allocating it to the Balancing Authorities. The field trial for BAL-003-1 is testing an allocation methodology based on the amount of load and generation in the BA. This is to accommodate the wide spectrum of BAs from generation-only all the way to load-only.

Frequency Response Sharing Groups (FRSGs)

This standard proposes an entity called FRSG, which is defined as:

> *A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.*

This standard allows Balancing Authorities to cooperatively form FRSGs as a means to jointly meet the FRS. There is no obligation to form or be a part of FRSGs. The members of the FRSG would determine how to allocate sanctions among its members. This standard does not mandate the formation of FRSGs, but allows them as a means to meet one of FERC's Order No. 693 directives.

FRSG performance may be calculated one of two ways:

- Calculate a group NI_A and measure the group response to all events in the reporting year on a single FRS Form 1, or
- Jointly submit the individual BAs' Form 1s, with a summary spreadsheet that sums each participant's individual event performance.

Frequency Response Obligation and Calculation

The basic Frequency Response Obligation is based on annual load and generation data reported in FERC Form 714 (where applicable, see below for non-jurisdictional entities) for the previous full calendar year. The basic allocation formula used by NERC is:

$$\mathrm{FRO_{BA}} = \mathrm{FRO_{Int}} \times \frac{\text{Annual Gen}_{\mathrm{BA}} + \text{Annual Load}_{\mathrm{BA}}}{\text{Annual Gen}_{\mathrm{Int}} + \text{Annual Load}_{\mathrm{Int}}}$$

Where:

- Annual $\mathrm{Gen_{BA}}$ is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
- Annual $\mathrm{Load_{BA}}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
- Annual $\mathrm{Gen_{Int}}$ is the sum of all Annual $\mathrm{Gen_{BA}}$ values reported in that interconnection.
- Annual $\mathrm{Load_{Int}}$ is the sum of all Annual $\mathrm{Load_{BA}}$ values reported in that interconnection.

Balancing Authorities that are not FERC jurisdictional should use the Form 714 Instructions to assemble and submit equivalent data. Until the BAL-003-1 process outlined in Attachment 1 is implemented, Balancing Authorities can approximate their FRO by multiplying their Interconnection's FRO by their share of Interconnection Bias. The data used for this calculation should be for the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which utilized data from 2011.

Balancing Authorities that merge or that transfer load or generation need to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation for the Interconnection remains the same and so that CPS limits can be adjusted.

Attachment A proposes the following Interconnection event criteria as a basis to determine an Interconnection's Frequency Response Obligation:

- Largest category C loss-of-resource (N-2) event.
- Largest total generating plant with common voltage switchyard.
- Largest loss of generation in the interconnection in the last 10 years.

With regard to the second objective above (determining Frequency Bias Settings and CPS limits), Balancing Authorities have been asked to perform annual reviews of their Frequency Bias Settings by measuring their Frequency Response, dating back to Policy 1. This obligation was carried forward into BAL-003-01.b. While the associated training document provided useful information, it left many of the details to the judgment of the person doing the analysis. The FRS Form 1 and FRS Form 2 provide a consistent, objective process for calculating Frequency Response to develop an annual measure, the FRM.

The FRM will be computed from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz". The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change of its net actual interchange on its tie lines with its adjacent Balancing Authorities divided by the change in interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their net actual interchange values to account for factors such as nonconforming loads. FRS Form 1 shows the types of adjustments that are allowed.)

A standardized sampling interval of approximately 20 to 52 seconds will be used in the computation of SEFRD values. Microsoft Excel® spreadsheet interfaces for EMS scan rates of 2 through 6 seconds are provided to support the computation.

Single Event Frequency Response Data[8]

The use of a "single event measure" was considered early in the development of the FRS for compliance because a single event measure could be enforced for each event on the interconnection making compliance enforcement a simpler process. The variability of the measurement of Frequency Response for an individual BA for an individual Disturbance event was evaluated to determine its suitability for use as a compliance measure. The individual Disturbance events were normalized and plotted for each BA on the Eastern and Western Interconnections. This data was plotted with a dot representing each event. Events with a measured Frequency Response above the FRO were shown as blue dots and events with a measured Frequency Response below the FRO were shown as red dots. In order to show the full variability of the results the plots have been provided with two scales, a large scale to show all of the events and small scale to show the events closer to the FRO or a value of 1.0. This data is presented on four charts titled Frequency Response Events as Normalized by FRO.

Analysis of this data indicates a single event based compliance measure is unsuitable for compliance evaluation when the data has the large degree of variability shown in these charts. Based on the field trial data provided, only 3 out of 19 BAs on the Western Interconnection would be compliant for all events with a standard based on a single event measure. Only 1 out of 31 BAs on the Eastern Interconnection would be compliant for all events with a standard based on a single event measure. The general consensus of the industry is that there is not a reliability issue with insufficient Frequency Response on any of the North American Interconnections at this time. Therefore, it is unreasonable to even consider a standard that would indicate over 90% of the BAs in North American to be non-compliant with respect to maintaining sufficient Frequency Response to maintain adequate reliability.

In an attempt to balance the workload of Balancing Authorities with the need for accuracy in the FRM, the standard will require at least 20 samples selected during the course of the year to compute the FRM. Research conducted by the FRSDT indicated that a Balancing Authority's FRM will converge to a reasonably stable value with at least 20 samples.

Balancing Authority

Sample Size
In order to support field trial evaluations of sample size, sampling intervals, and aggregation techniques, the FRSDT will be retrieving scan rate data from the Balancing Authorities for each SEFRD. Additional frequency events may also be requested for research purposes, though they will not be included in the FRM computation.

FERC Order No. 693 directed the ERO (at P 375) to define the number of Frequency Response surveys that were conducted each year and to define a necessary amount of Frequency Response. R1 addresses both of these directives:

- There is a single annual survey of at least 20 events each year.
- The FRM calculated on FRS Form 1 is compared by the ERO against the FRO determined 12 months earlier (when the last FRS Form 1 was submitted) to verify the Balancing Authority provided its share of Interconnection Frequency Response.

Median as the Standard's Measure of Balancing Authority Performance
The FRSDT evaluated different approaches for "averaging" individual event observations to compute a technically sound estimate of Frequency Response Measure. The MW contribution for a single BA in a multi-BA Interconnection is small compared to the minute to minute changes in load, interchange and generation. For example, a 3000 MW BA in the Eastern Interconnection may only be called on to contribute 10MW for the loss of a 1000MW. The 10 MW of governor and load response may easily be masked as a coincident change in load.

In general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FRSDT has shown the Median to be less influenced by noise in the measurement process and the team has chosen the median as the initial metric for calculating the BAs' Frequency Response Measure.

The FRSDT performed extensive empirical studies and engaged in lively discussions in an attempt to determine the best aggregation technique for a sample set size of at least 20 events. Mean, median, and linear regression techniques were used on a trial basis with the data that was available during the early phases of the effort.

A key characteristic of the "aggregation challenge" is related to the use of actual net interchange data for measuring frequency response. The tie line flow measurements are varying continuously due to other operational phenomena occurring concurrently with the provision of frequency response. (*See* Appendix 1 for details.) All samples have "noise" in them, as most operational personnel who have computed the frequency response of their BA can attest. What has also become apparent to the FRSDT is that while the majority of the frequency response samples have similar levels of noise in them, a few of the samples may have much larger errors in them than the others that result in unrepresentative results. And with the sample set size of interest, it is common to have unrepresentative errors in these few samples to be very large and asymmetric. For example, one BA's subject matter expert observed recently that 4 out of 31 samples had a much larger error contribution than the other 27 samples, and that 3 out of 4 of the very high error samples grossly underestimated the frequency response. The median value demonstrated greater resiliency to this data quality problem than the mean with this data set. (The median has also demonstrated superiority to

linear regression in the presence of these described data quality problems in other analyses conducted by the FRSDT, but the linear regression showed better performance than the mean.)

The above can be demonstrated with a relatively simple example. Let's assume that a Balancing Authority's true frequency response has an average value of -200 MW/ .1 Hz. Let's also assume that this Balancing Authority installed "special" perfect metering on key loads and generators, so that we could know the true frequency response of each sample. And then we will compare them with that measured by typical tie line flow metering, with the kind of noise and error that occurs commonly and "not so commonly". Let's start with the following 4 samples having a common level of noise, with MW/ .1 Hz as the unit of measurement.

Perfect measurement	Noise	Samples from tie lines
-190	-30	-220
-210	-20	-230
-220	10	-210
-180	20	-160
-200	Mean	-205
-200	Median	-215

Now let's add a fifth sample, which is highly contaminated with noise and error that grossly underestimates frequency response.

Perfect measurement	Noise	Samples from tie lines
-190	-30	-220
-210	-20	-230
-220	10	-210
-180	20	-160
-200	250	+50
-200	Mean	-154
-200	Median	-210

It is clear from the above simplistic example that the mean drops by about 25% while the median is affected minimally by the single highly contaminated value.

Based on the analyses performed thus far, the FRSDT believes that the median's superior resiliency to this type of data quality problem makes it the best aggregation technique at this time. However, the FRSDT sees merit and promise in future research with sample filtering combined with a technique such as linear regression.

When compared with the mean, linear regression shows superior performance with respect to the elimination of noise because the measured data is weighted by the size of the frequency change associated with the event. Since the noise is independent from frequency change, the greater weighting on larger events provides a superior technique for reducing the effect of noise on the results.

However, linear regression does not provide a better method when dealing with a few samples with large magnitudes of noise and unrepresentative error. There are only two alternatives to improve over the use of median when dealing with these larger unrepresentative errors:

1. Increase the sample size, or
2. Actively eliminate outliers due to unrepresentative error.

Unfortunately, the first alternative, increasing the sample size is not available because significantly more sample events are not available within the measurement time period of one year. Linear regression techniques are being investigated that have an active outlier elimination algorithm that would eliminate data that lie outside ranges of the 96th percentile and 99th percentile, for example.

Still, the use of linear regression has value in the context of this standard. The NERC Resources Subcommittee will use linear regression to evaluate Interconnection frequency response, particularly to evaluate trends, seasonal impacts, time of day influences, etc. The Good Practices and Tools section of this document outlines how a BA can use linear regression to develop a predictive tool for its operators.

Additional discussion on this topic is contained in "Appendix 1 – Data Quality Concerns Related to the Use of Actual Net Interchange Value" of this document.

The NERC Frequency Response Initiative Report addressed the relative merits of using the median versus linear regression for aggregating single event frequency response samples into a frequency response measurement score for compliance evaluation. This report provided 11 evaluation criteria as a basis for recommending the use of linear regression instead of the median for the frequency response measurement aggregation technique. The FRSDT made its own assessment on the basis of these evaluation criteria on September 20, 2012, but concluded that the median would be the best aggregation technique to use initially when the relative importance of each criterion was considered. A brief summary of the FRSDT majority consensus on the basis of each evaluation criterion is provided below.

- Provides two dimensional measurement – The FRSDT agrees that the two dimensional concept is a useful way to perceive frequency response characteristics, and that it may be useful for potential future modeling activities. Better data quality would increase support for such future efforts, and the use of the median for initial compliance evaluations within BAL-003-1 should not hinder any such effort. The FRSDT perceived this as a mild advantage for linear regression.
- Represents nonlinear characteristics – With considerations similar to those applied to the previous criterion, the FRSDT perceived this as a mild advantage for linear regression.
- Provides a single best estimator – The FRSDT gave minimal importance to the characteristic of the median averaging the middle values when used with an even number of samples.
- Is part of a linear system - With considerations similar to those applied to the first two criteria, the FRSDT perceived this as a mild advantage for linear regression (particularly in the modeling area.)
- Represents bimodal distributions – The FRSDT gave minimal weight of this criterion, as a change in Balancing Authority footprint does not seem to be addressed adequately by any aggregation technique.
- Quality statistics available – The FRSDT perceived this as a mild advantage for linear regression in that the statistics would be coupled directly to the compliance evaluation. The FRSDT also included this criterion as part of the modeling advantages cited above.

The FRSDT supports collecting data and performing quality statistical analysis. If it is determined that the use of the median, as opposed to a mean or linear regression aggregation, is yielding undesirable consequences, the FRSDT recommends that other aggregation techniques be re-evaluated at that time.

- Reducing influence of noise - This is the dominant concern of the FRSDT, and it perceives the median to have a major advantage over linear regression in addressing noise in the change in actual net interchange calculation. The FRSDT bases this judgment on: prior FRSDT studies that have shown that the median produces more stable results; the data used in the NERC Frequency Response Initiative document exhibits large quantities of noise; prior efforts of FRSDT members in performing frequency response sampling for their own Balancing Authorities over many years; and similar observations of noise in the CERTS frequency Monitoring Application. The FRSDT has serious concerns that the influence of noise has a greater tendency to yield a "false positive" compliance violation with linear regression than with the median. Also, limited studies performed by the FRSDT indicates the possibility that the resultant frequency response measure would yield more measurement variation across years with linear regression versus the median while the actual Balancing Authority performance remains unchanged.
- Reducing the influence of outliers – This is related to the previous criterion. The FRSDT recognizes four main sources of noise: concurrent operating phenomena (described elsewhere in this document), transient tie line flows for nearby contingencies, data acquisition time skew in tie line data measurements, and time skew and data compression issues in archiving techniques and tools such as PI. Some outliers may be caused in part by true variation in the actual frequency response, and it is desirable to include those in the frequency response measure. The FRSDT supports efforts in the near future to distinguish between outliers caused by noise versus true frequency response, and progress in this area may make it feasible and desirable to replace the median with linear regression, or some other validated technique. The FRSDT does note that this is a substantial undertaking, and it would require substantial input from a sufficient number of experts to help distinguish noise from true frequency response.
- Easy to calculate – The FRSDT perceives this to be a minor to moderate advantage for the median. However, more complex (but reasonably so) techniques would receive more support if clear progress can be made in noise elimination.
- Familiar indicator – The FRSDT perceives this to be a minor to moderate advantage for the median. However, more complex (but reasonably so) techniques would receive more support if clear progress can be made as a result of noise elimination.
- Currently used as a measure in BAL-003 – The present standard refers to an average and does not provide specific guidance on the computation of that average, but the FRSDT puts minimal weight on this evaluation criterion.

In summary, the FRSDT perceives an approximate balance between the modeling advantage for linear regression and the simplicity advantage of the median. However, the clear determinant in endorsing the use of the median is the data quality issue related to concurrent operational phenomena, transient tie line flows, and data acquisition and archiving limitations.

FERC Order No. 693 also directed the Standard (at P 375) to identify methods for Balancing Authorities to obtain Frequency Response. Requirement R1 allows Balancing Authorities to participate in Frequency Response Sharing Groups (FRSGs) to provide or obtain Frequency Response. These may be the same FRSGs that cooperate for BAL-002-0 or may be FRSGs that form for the purposes of BAL-003-1.

If BAs participate as an FRSG for BAL-003-1, compliance is based on the sum of the participants' performance.

Two other ways that BAs could obtain Frequency Response are through Supplemental Service or Overlap Regulation Service:

- No special action is needed if a BA provides or receives supplemental regulation. If the regulation occurs via Pseudo Tie, the transfer occurs automatically as part of Net Actual Interchange (NIA) and in response to information transferred from recipient to provider.
- If a BA provides overlap regulation, its FRS Form 1 will include the Frequency Bias setting as well as peak load and generation of the combined Balancing Authority Areas. The FRM event data will be calculated on the sum of the provider's and recipient's performance.

In the Violation Severity Levels for Requirement R1, the impact of a BA not having enough frequency response depends on two factors:

- Does the Interconnection have sufficient response?
- How short is the BA in providing its FRO?

The VSL takes these factors into account. While the VSLs look different than some other standards, an explanation would be helpful.

VSLs are a starting point for the enforcement process. The combination of the VSL and VRF is intended to measure a violation's impact on reliability and thus levy an appropriate sanction. Frequency Response is an interconnection-wide resource. The proposed VSLs are intended to put multi-BA Interconnections on the same plane as single-BA Interconnections.

Consider a small BA whose performance is 70% of its FRO. If all other BAs in the Interconnection are compliant, the small BA's performance has negligible impact on reliability, yet would be sanctioned at the same level as a BA who was responsible for its entire Interconnection. It is not rational to sanction this BA the same as a single BA Interconnection that had insufficient Frequency Response, because this would treat multi-BA Interconnections more harshly than single BA Interconnections on a significant scale.

The "Lower" and "Medium" VSLs say that the Interconnection has sufficient Frequency Response but individual BAs are deficient by small or larger amounts respectively. The High and Severe VSLs say the Interconnection does not meet the FRO and assesses sanctions based on whether the BA is deficient by a small or larger amount respectively.

Requirement 2

R2. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined in accordance with Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO.

Background and Rationale

Attachment A of the Standard discusses the process the ERO will follow to validate the BA's FRS Form 1 data and publish the official Frequency Bias Settings. Historically, it has taken multiple rounds of validation and outreach to confirm each BA's data due to transcription errors, misunderstanding of instructions, and other issues. While BAs historically submit Bias Setting data by January 1, it often takes one or more months to complete the process.

The target is to have BAs submit their data by January 10. The BAs are given 30 days to assemble their data since the BAs are dependent on the ERO to provide them with FRS Form 1, and there may be process delays in distributing the forms since they rely on identification of frequency events through November 30 of the preceding year.

Frequency Bias Settings generally change little from year to year. Given the fact that BAs can encounter staffing or EMS change issues coincident with the date the ERO sets for new Frequency Bias Setting implementation, the standard provides a 24 hour window on each side of the target date.

To recap the annual process:

1. The ERO posts the official list of frequency events to be used for this Standard in early December. The FRS Form 1 for each Interconnection will be posted shortly thereafter.

2. The Balancing Authority submits its revised annual Frequency Bias Setting value to NERC by January 10.

3. The ERO and the Resources Subcommittee validate Frequency Bias Setting values, perform error checking, and calculate, validate, and update CPS2 L10 values. This data collection and validation process can take as long as two months.

4. Once the L10 and Frequency Bias Setting values are validated, The ERO posts the values for the upcoming year and also informs the Balancing Authorities of the date on which to implement revised Frequency Bias Setting values. Implementation typically would be on or about March 1st of each year.

BAL-003-0.1b standard requires a minimum Frequency Bias Setting equal in absolute value to one percent of the Balancing Authority's estimated yearly peak demand (or maximum generation level if native load is not served). For most Balancing Authorities this calculated amount of Frequency Bias is significantly greater in absolute value than their actual Frequency Response characteristic (which represents an over-bias condition) resulting in over-control

since a larger magnitude response is realized. This is especially true in the Eastern Interconnection where this condition requires excessive secondary frequency control response which degrades overall system performance and increases operating cost as compared to requiring an appropriate balance of primary and secondary frequency control response.

Balancing Authorities were given a minimum Frequency Bias Setting obligation because there had never been a mandatory Frequency Response Obligation. This historic "one percent of peak per 0.1Hz" obligation, dating back to NERC's predecessor, NAPSIC, was intended to ensure all BAs provide some support to Interconnection frequency.

The ideal system control state exists when the Frequency Bias Setting of the Balancing Authority exactly matches the actual Frequency Response characteristic of the Balancing Authority. If this is not achievable, over-bias is significantly better from a control perspective than under-bias with the caveat that Frequency Bias is set relatively close in magnitude to the Balancing Authority actual Frequency Response characteristic. Setting the Frequency Bias to better approximate the Balancing Authority natural Frequency Response characteristic will improve the quality and accuracy of ACE control, CPS & DCS and general AGC System control response. This is the technical basis for recommending an adjustment to the long standing "1% of peak/0.1Hz" Frequency Bias Setting. The Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard is intended to bring the Balancing Authorities' Frequency Bias Setting closer to their natural Frequency Response. Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard balances the following objectives:

- Bring the Frequency Bias Setting and Frequency Response closer together.
- Allow time to analyze impact on other Standards (CPS, BAAL and to a lesser extent DCS) by adjustments in the minimum Frequency Bias Setting, by accommodating only minor adjustments.
- Do not allow the Frequency Bias Setting minimum to drop below natural Frequency Response, because under-biasing could affect an Interconnection adversely.

Additional flexibility has been added to the Frequency Bias Setting based on the actual Frequency Response (FRM) by allowing the Frequency Bias Setting to have a value in the range from 100% of FRM to 125% of FRM. This change has been included for the following reasons:

- When the new standardized measurement method is applied to BAs with a Frequency Response close to the interconnection minimum response, the requirement to use FRM is as likely to result in a Frequency Bias Setting below the actual response as it is to result in a response above the actual response. From a reliability perspective, it is

always better to have a Frequency Bias Setting slightly above the actual Frequency Response.

- As with single BA interconnections, the tuning of the control system may require that the BA implement a Frequency Response Setting slightly greater in absolute terms than its actual Frequency Response to get the best performance.

- The new standardized measurement method for determining FRM in some cases results in a measured Frequency Response significantly lower than the previous methods used by some BAs. It is desirable to not require significant change in the Frequency Bias Setting for these BAs that experience a reduction in their measured Frequency Response.

Requirement 3

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is:

- *Less than zero at all times, and*
- *Equal to or more negative than its Frequency Response Obligation when the Frequency varies from 60 Hz by more that +/- 0.036 Hz.*

Background and Rationale

In multi-Balancing Authority interconnections, the Frequency Bias Setting should be coordinated among all BAs on the interconnection. When there is a minimum Frequency Bias Setting requirement, it should apply for all BAs. However, BAs using a variable Frequency Bias Setting may have non-linearity in their actual response for a number of reasons including the dead-bands implemented on their generator governors. The measurement to ensure that these BAs are conforming to the interconnection minimum is adjusted to remove the dead-band range from the calculated average Frequency Bias Setting actually used. For BAs using variable bias, FRS Form 1 has a data entry location for the previous year's average monthly Bias. The Balancing Authority and the ERO can compare this value to the previous year's Frequency Bias Setting minimum to ensure R3 has been met.

On single BA interconnections, there is no need to coordinate the Frequency Bias Setting with other BAs. This eliminates the need to maintain a minimum Frequency Bias Setting for any reason other than meeting the reliability requirement as specified by the Frequency Response Obligation.

Requirement 4

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to either:

- *The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or*
- *The Frequency Bias Setting as shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities' Areas.*

Background and Rationale

This requirement reflects the operating principles first established by NERC Policy 1 and is similar to Requirement R6 of the approved BAL-003-0.1b standard. Overlap Regulation Service is a method of providing regulation service in which the Balancing Authority providing the regulation service incorporates another Balancing Authority's actual interchange, frequency response, and schedules into the providing Balancing Authority's AGC/ACE equation.

As noted earlier, a BA that is providing Overlap Regulation will report the sum of the Bias Settings in its FRS Form 1. Balancing Authorities receiving Overlap Regulation Service have an ACE and Frequency Bias Setting equal to zero (0).

How this Standard Meets the FERC Order 693 Directives

FERC Directive

The following is the relevant paragraph of Order No. 693.

> *Accordingly, the Commission approves Reliability Standard BAL-003-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to BAL-003-0 through the Reliability Standards development process that: (1) includes Levels of Non-Compliance; (2) determines the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other requirements of the Reliability Standard are being met, and to modify Measure M1 based on that determination and (3) defines the necessary amount of Frequency Response needed for Reliable Operation for each balancing authority with methods of obtaining and measuring that the frequency response is achieved.*

1. Levels of Non-Compliance

VRFs and VSLs are an equally effective way of assigning compliance elements to the standard.

2. Determine the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other Requirements of the Reliability Standard are met

BAL-003 V0 R2 (the basis of Order No. 693) deals with the calculation of Frequency Bias Setting such that it reflects natural Frequency Response.

The drafting team has determined that a sample size on the order of at least 20 events is necessary to have a high confidence in the estimate of a BA's Frequency Response. Selection of the frequency excursion events used for analysis will be done via a method outlined in Attachment A to the Standard.

On average, these events will represent the largest 2-3 "clean" frequency excursions occurring each month.

Since Frequency Bias Setting is an annual obligation, the survey of the at least 20 frequency excursion events will occur once each year.

3. Define the necessary amount of Frequency Response needed for Reliable Operation for each Balancing Authority with methods of obtaining and measuring that the frequency response is achieved

Necessary Amount of Frequency Response

The drafting team has proposed the following approach to defining the necessary amount of frequency response. In general, the goal is to avoid triggering the first step of under-frequency load shedding (UFLS) in the given Interconnection for reasonable contingencies expected. The

methodology for determining each Interconnection's and Balancing Authority's obligation is outlined in Attachment A to the Standard.

It should be noted the standard cannot guarantee there will never be a triggering of UFLS as the magnitude of "point C" differs throughout an interconnection during a disturbance and there are local areas that see much wider swings in frequency.

The contingency protection criterion is the largest reasonably expected contingency in the Interconnection. This can be based on the largest observed credible contingency in the previous 10 years or the largest Category C event for the Interconnection.

Attachment A to the standard presents the base obligation by Interconnection and adds a Reliability Margin. The Reliability Margin included addresses the difference between Points B and C and accounts for variables.

For multiple BA interconnections, the Frequency Response Obligation is allocated to BAs based on size. This allocation will be based on the following calculation:

$$\mathrm{FRO_{BA}} = \mathrm{FRO_{Int}} \times \frac{\text{Annual Gen}_{\mathrm{BA}} + \text{Annual Load}_{\mathrm{BA}}}{\text{Annual Gen}_{\mathrm{Int}} + \text{Annual Load}_{\mathrm{Int}}}$$

Methods of Obtaining Frequency Response

The drafting team believes the following are valid methods of obtaining Frequency Response:

- Regulation services.
- Contractual service. The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1. While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.

Measuring that the Frequency Response is Achieved

FRS Form 1 and the underlying data retained by the BA will be used for measuring whether Frequency Response was provided. FRS Form 1 will provide the guidance on how to account for and measure Frequency Response.

Going Beyond the Directive

Based on the combined operating experience of the SDT, the drafting team consensus is that each Interconnection has sufficient Frequency Response. If margins decline, there may be a need for additional standards or tools. The drafting team and the Resources Subcommittee are working with the ERO on its Frequency Response Initiative to develop processes and good practices so the Interconnections are prepared. These good practices and tools are described in the following section.

The drafting team is also evaluating a risk-based approach for basing the Interconnection Frequency Response Obligation on an historic probability density of frequency error, and for allocating the obligation on the basis of the Balancing Authority's average annual ACE share of frequency error. This allocation method uses the inverse of the rationale for allocating the CPS1 epsilon requirement by Bias share.

Good Practices and Tools

Background

This section outlines tips and tools to help Balancing authorities meet the Frequency Response Standard or to operate more reliably. If you have suggested additions, please send them to balancing@nerc.com.

Identifying and Estimating Frequency Responsive Reserves

Knowing the quantity and depth of frequency responsive reserves in real time is a possible next step to being better prepared for the next event. The challenge in achieving this is having the knowledge of the capabilities of all sources of frequency response. Presently the primary source of Frequency Response remains with the generation resources in our fleets.

Understanding how each of these sources performs to changes in system frequency and knowing their limitations would improve the BA's ability to measure frequency responsive reserves. Presently there are only guidelines, criteria and protocols in some regions of the industry that identify specific settings and performance expectations of Primary Frequency Response of resources.

One method of gaining a better understanding of performance is to measure performance during actual events that occur on the system. Measuring performance during actual events would only provide feedback for performance during that specific event and would not provide insight into depth of response or other limitations.

Repeated measurements will increase confidence in expected performance. NERC modeling standards are in process to be revised that will improve the BA's insight into predicting available frequency responsive reserves. However, knowing how resources are operated, what modes of operation provide sustained Primary Frequency Response and knowing the operating range of this response would give the BA the knowledge to accurately predict frequency response and the amount of frequency responsive reserves available in real time.

Some benefits have been realized by communicating to generation resources (GO) the importance of operating in modes that allow Primary Frequency Response to be sustained by the control systems of the resource. Other improvements in implementation of Primary Frequency Response have been achieved through improved settings on turbine governors through the elimination of "step" frequency response with the simultaneous reduction in governor dead-band settings.

Improvements in the full AGC control loop of the generating resource, which accounts for the expected Primary Frequency Response, have improved the delivery of quality Primary Frequency Response while minimizing secondary control actions of generators. Some of these actions can provide quick improvement in delivery of Primary Frequency Response.

Once Primary Frequency Response sources are known, the BA could calculate available reserves that are frequency responsive. Planning for these reserves during normal and emergency operations could be developed and added to the normal planning process.

Using FRS Form 1 Data

The information collected for this standard can be supplemented by a few data points to provide the Balancing Authority useful tools and information. The BA could do a regression analysis of its frequency response against the following values:

- Load (value A).
- Interchange (Value A).
- Total generation.
- Spinning reserve.

While the last two values above are not part of Form 1, they should be readily available. Small BAs might even include headroom on its larger generators as part of the regression.

The regression would provide a formula the BA could program in its EMS to present the operator a real time estimate of the BA's Frequency Response.

Statistical outliers in the regression would point to cases meriting further inspection to find causes of low Frequency Response or opportunities for improvement.

Tools

Single generating resource performance evaluation tools for steam turbine, combustion turbine (simple cycle or combined cycle) and for intermittent resources are available at the following link. http://texasre.org/standards_rules/standardsdev/rsc/sar003/Pages/Default.aspx.

These tools and the regional standard associated with them are in their final stages of development in the Texas region.

These tools will be posted on the NERC website.

Appendix 1 - Data Quality Concerns Related To The Use Of The Actual Net Interchange Value

Actual net interchange for a typical Balancing Authority (BA) is the summation of its tie lines to other BAs. In some cases, there are pseudo-ties in it which reflect the effective removal or addition of load and/or generation from another BA, or it could include supplemental regulation as well. But in the typical scenario, actual net interchange values that are extracted from EMS data archiving can be influenced by data latency times in the data acquisition process, and also any timestamp skewing in the archival process.

Of greater concern, however, are the inevitable variations of other operating phenomena occurring concurrently with a frequency event. The impacts of these phenomena are superimposed on actual net interchange values along with the frequency response that we wish to measure through the use of the actual net interchange value.

To explore this issue further, let's begin with the idealized condition:

- frequency is fairly stable at some value near or a little below 60 Hz
- ACE of the non-contingent BA of interest is 0 and has been 0 for an extended period, and AGC control signals have not been issued recently
- Actual net interchange is "on schedule", and there are no schedule changes in the immediate future
- BA load is flat
- All generators not providing AGC are at their targets
- Variable generation such as wind and solar are not varying
- Operators have not directed any manual movements of generation recently

And when the contingency occurs in this idealized state, the change in actual net interchange will be measuring only the decline in load due to lesser frequency and generator governor response, and, none of the contaminating influences. While the ACE may become negative due to the actual frequency response being less than that called for by the frequency bias setting within the BA's AGC system, this contaminating influence on measuring frequency response will not appear in the actual net interchange value if the measurement interval ends before the generation on AGC responds.

Now let's explore the sensitivity of the resultant frequency response sampling to the relaxation of these idealized circumstances.

1. The "60 Hz load" increases moderately due to time of day concurrent with the frequency event. If the frequency event happens before AGC or operator-directed manual load adjustments occur, then the actual net interchange will be reduced by the moderate increase in load and the frequency response will be underestimated. But if the frequency event happens while AGC response and/or manual adjustments occur, then the actual net interchange will be increased by the AGC response (and/or manual adjustments) and the frequency response will be overestimated.

2. The “60 Hz load” decreases moderately due to time of day concurrent with the frequency event. If the frequency event happens before AGC or operator-directed manual load adjustments occur, then the actual net interchange will be increased by the moderate reduction in load and the frequency response will be overestimated. But if the frequency event happens while AGC response and/or manual adjustments occur, then the actual net interchange will be decreased by the AGC response (and/or manual adjustments) and the frequency response will be underestimated.
3. In anticipation of increasing load during the next hour, the operator increases manual generation before the load actually appears. If the frequency event happens while the generation “leading” the load is increasing, then the actual net interchange will be increased by the increase in manual generation and the frequency response will be overestimated. But if the frequency event occurs when the result of AGC signals sent to offset the operator’s leading actions take effect, then the actual net interchange will be decreased and the frequency response is underestimated.
4. In anticipation of decreasing load during the next hour, the operator decreases manual generation before the load actually declines. If the frequency event happens while the generation “leading” the load downward is decreasing, then the actual net interchange will be decreased by the reduction in manual generation and the frequency response will be underestimated. But if the frequency event occurs when the result of AGC signals sent to offset the operator’s leading actions take effect, then the actual net interchange will be increased and the frequency response is overestimated.
5. A schedule change to export more energy is made at 5 minutes before the top of the hour. The BA’s “60 Hz load” is not changing. The schedule change is small enough that the operator is relying on upward movement of generators on AGC to provide the additional energy to be exported. The time at which the AGC generators actually begin to provide the additional energy is dependent on how much time passes before the AGC algorithm gets out of its deadbands, the individual generator control errors get large enough for sending out the control signal, and maybe 20 seconds to 3 minutes for the response to be effected. The key point here is that it is not clear when the effects of a schedule change, as manifested in a change in generation and then ultimately a change in actual net interchange, will occur.
6. With the expected penetration of wind in the near future, unanticipated changes in their output will tend to affect actual net interchange and add noise to the frequency response observation process.

To a greater or lesser extent, 1 through 4 above are happening continuously for the most part with most BAs in the Eastern and Western Interconnections. The frequency response is buried within the typical hour to hour operational cacophony superimposed on actual net interchange values. The choice of metrics will be important to artfully extract frequency response from the noise and other unrepresentative error.

Introduction

This document provides background on the development, testing and implementation of BAL-003-1 - Frequency Response Standard (FRS).[1] The intent is to explain the rationale and considerations for the Requirements of this standard and their associated compliance information. The document also provides good practices and tips for Balancing Authorities ("BAs") with regard to Frequency Response.

In Order No. 693, the Federal Energy Regulatory Commission ("FERC" or the "Commission") directed additional changes to BAL-003.[2] This document explains how compliance with those directives are met by BAL-003-1.

The original Standards Authorization Request ("SAR"), finalized on June 30, 2007, assumed there was adequate Frequency Response in all the North American Interconnections. The goal of the SAR was to update the Standard to make the measurement process of frequency response more objective and to provide this objective data to Planners and Operators for improved modeling. The updated models will improve understanding of the trends in Frequency Response to determine if reliability limits are being approached. The Standard would also lay the process groundwork for a transition to a performance-based Standard if reliability limits are approached.

This document will be periodically updated by the FRS Drafting Team (FRSDT) until the Standard is approved. Once approved, this document will then be maintained and updated by the ERO and the NERC Resources Subcommittee to be used as a reference and training resource.

Background

This section discusses the different components of frequency control and the individual components of Primary Frequency Control also known as Frequency Response.

Frequency Control

Most system operators generally have a good understanding of frequency control and Bias Setting as outlined in the balancing standards and the references to them in the NERC Operating Manual. Frequency control can be divided into four overlapping windows of time as outlined below.

> **Primary Frequency Control (Frequency Response) –** Actions provided by the Interconnection to arrest and stabilize frequency in response to frequency deviations. Primary Control comes from automatic generator governor response (also known as speed

[1] Unless otherwise designated herein, all capitalized terms shall have the meaning set forth in the Glossary of Terms Used in NERC Reliability Standards, available here: http://www.nerc.com/files/Glossary_of_Terms.pdf.

regulation), load response (typically from motors), and other devices that provide an immediate response based on local (device-level) control systems.

Secondary Frequency Control – Actions provided by an individual BA or its Reserve Sharing Group to correct the resource – load unbalance that created the original frequency deviation, which will restore both Scheduled Frequency and Primary Frequency Response. Secondary Control comes from either manual or automated dispatch from a centralized control system.

Tertiary Frequency Control – Actions provided by Balancing Authorities on a balanced basis that are coordinated so there is a net zero effect on Area Control Error (ACE). Examples of Tertiary Control include dispatching generation to serve native load; economic dispatch; dispatching generation to affect Interchange; and re-dispatching generation. Tertiary Control actions are intended to replace Secondary Control Response by reconfiguring reserves.

Time Control includes small offsets to scheduled frequency to keep long term average frequency at 60 Hz.

Primary Frequency Control – Frequency Response

Primary Frequency Control, also known generally as **Frequency Response**, is the first stage of overall frequency control and is the response of resources and load to a locally sensed change in frequency in order to arrest that change in frequency. Frequency Response is automatic, not driven by any centralized system, and begins within seconds rather than minutes. Different resources, loads, and systems provide Frequency Response with different response times, based on current system conditions such as total resource/load and their respective mix.

The proposed NERC Glossary of Terms defines **Frequency Response** as:

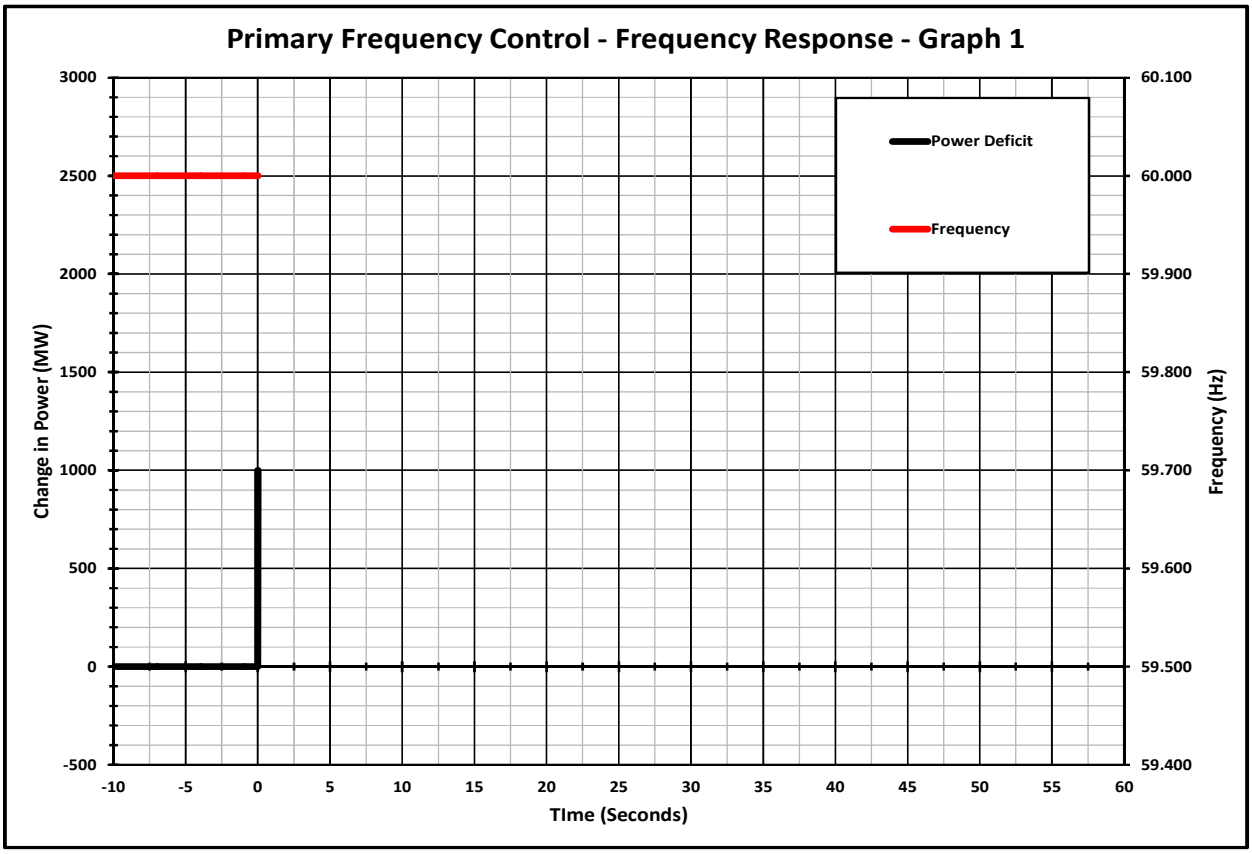
- (Equipment) The immediate and automatic reaction or response of power from a system or power from elements of the system to a change in locally sensed system frequency.
- (System) The sum of the change in demand, and the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 Hertz (MW/0.1 Hz).

As noted above, Frequency Response is the characteristic of load and generation within Balancing Authorities and Interconnections. It reacts or responds with changes in power to attempted changes in load-resource balance that result in changes to system frequency. Because the loss of a large generator is much more likely than a sudden loss of an equivalent amount of load, Frequency Response is typically discussed in the context of a loss of a large generator. Included within Frequency Response are many components of that response. Understanding Frequency Response and the FRS requires an understanding of each of these components and how they relate to each other.

Frequency Response Illustration

The following simple example is presented to illustrate the components of Frequency Response in graphical form. It includes a series of seven graphs that illustrate the various components of

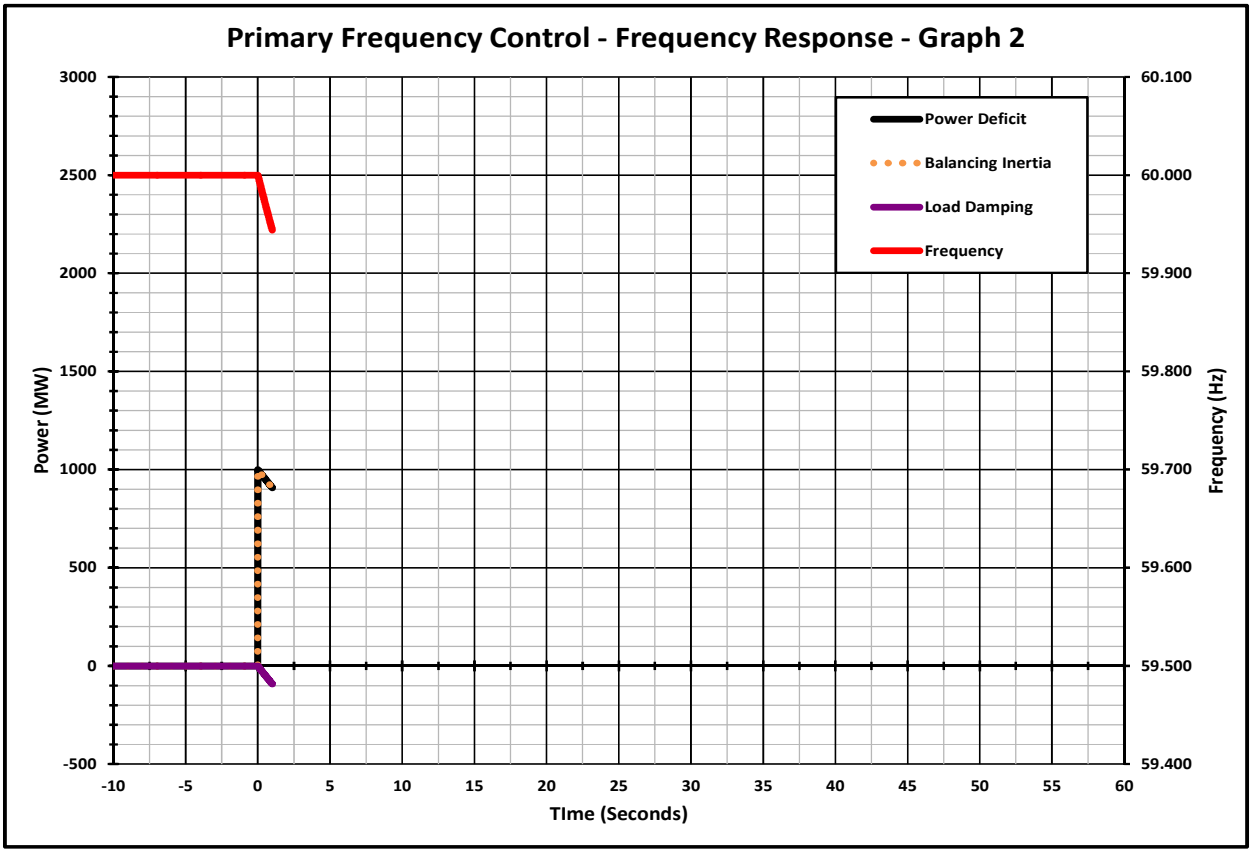
Frequency Response and a brief discussion of each describing how these components react to attempted changes in the load-resource balance and resulting changes in system frequency. The illustration is based on an assumed Disturbance event of the sudden loss of 1000 MW of generation. Although a large event is used to illustrate the response components, even small frequently occurring events will result in similar reactions or responses. The magnitude of the event only affects the shape of the curves on the graph; it does not obviate the need for Frequency Response.



The first graph, Primary Frequency Control – Frequency Response – Graph 1, presents a sudden loss of generation of 1000 MW. The components are presented relative to time as shown on the horizontal Time axis in seconds. This simplified example assumes a Disturbance event of the sudden loss of generation resulting from a breaker trip that instantaneously removes 1000 MW of generation from the interconnection. This sudden loss is illustrated by the power deficit line shown in black using the MW scale on the left. Interconnection frequency is illustrated by the frequency line shown in red using the Hertz scale on the right. Since the Scheduled Frequency is normally 60 Hz, it is assumed that this is the frequency when the Disturbance event occurs.

Even though the generation has tripped and power injected by the generator has been removed from the interconnection, the loads continue to use the same amount of power. The

"Law of Conservation of Energy"[3] requires that the 1000 MW must be supplied to the interconnection if energy balance is to be "conserved". This additional 1000 MW of power is produced by extracting kinetic energy that was stored in the rotating mass of all of the synchronized generators and motors on the interconnection – essentially using this equipment as a giant flywheel. The extracted energy supplies the "balancing inertia"[4] power required to maintain the power and energy balance on the interconnection. This balancing inertia power is produced by the generators' spinning inertial mass' resistance to the slowdown in speed of the rotating equipment on the interconnection that both provides the stored kinetic energy and reduces the frequency of the interconnection. This is illustrated in the second graph, Primary Frequency Control – Frequency Response – Graph 2, by the orange dots representing the balancing inertia power that exactly overlay and offset the power deficit.



As the frequency decreases, synchronized motors slow, as does the work they are providing, resulting in a decrease in load called "load damping." This load damping is the reason that the power deficit initially declines. Synchronously operated motors will contribute to load damping. Variable speed drives that are decoupled from the interconnection frequency do not

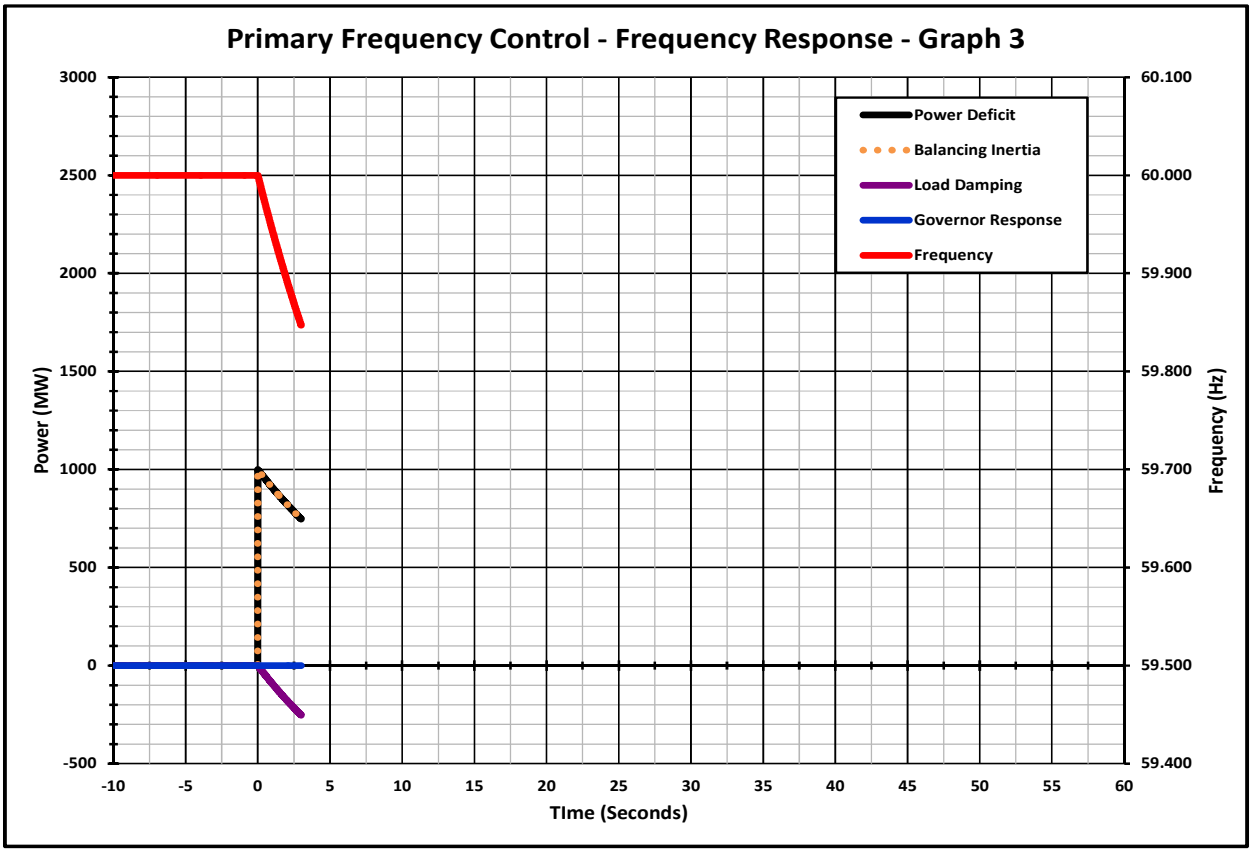
[3] The "Law of Conservation of Energy" is applied here in the form of power. If energy must be conserved, then power which is the first derivative of energy with respect to time, must also be conserved.

[4] The term "balancing Inertia" is coined here from the terms "inertial frequency response" and "balancing energy". Inertial frequency response is a common term used to describe the power supplied for this portion of the frequency response and balancing energy is a term used to describe the market energy supposedly purchased to restore energy balance.

contribute to load damping. In general, any load that does not change with interconnection frequency including resistive load will not contribute to load damping or Frequency Response.

It is important to note that the power deficit equals exactly the balancing inertia, indicating that there is no power or energy imbalance at any time during this process. What is normally considered as "balancing power or energy" is actually power or energy required to correct the frequency error from scheduled frequency. Any apparent power or energy imbalance is corrected instantaneously by the balancing inertia power and energy extracted from the interconnection. Thus the balancing function is really a frequency control function described as a balancing function because ACE is calculated in MWs instead of Hertz, frequency error.

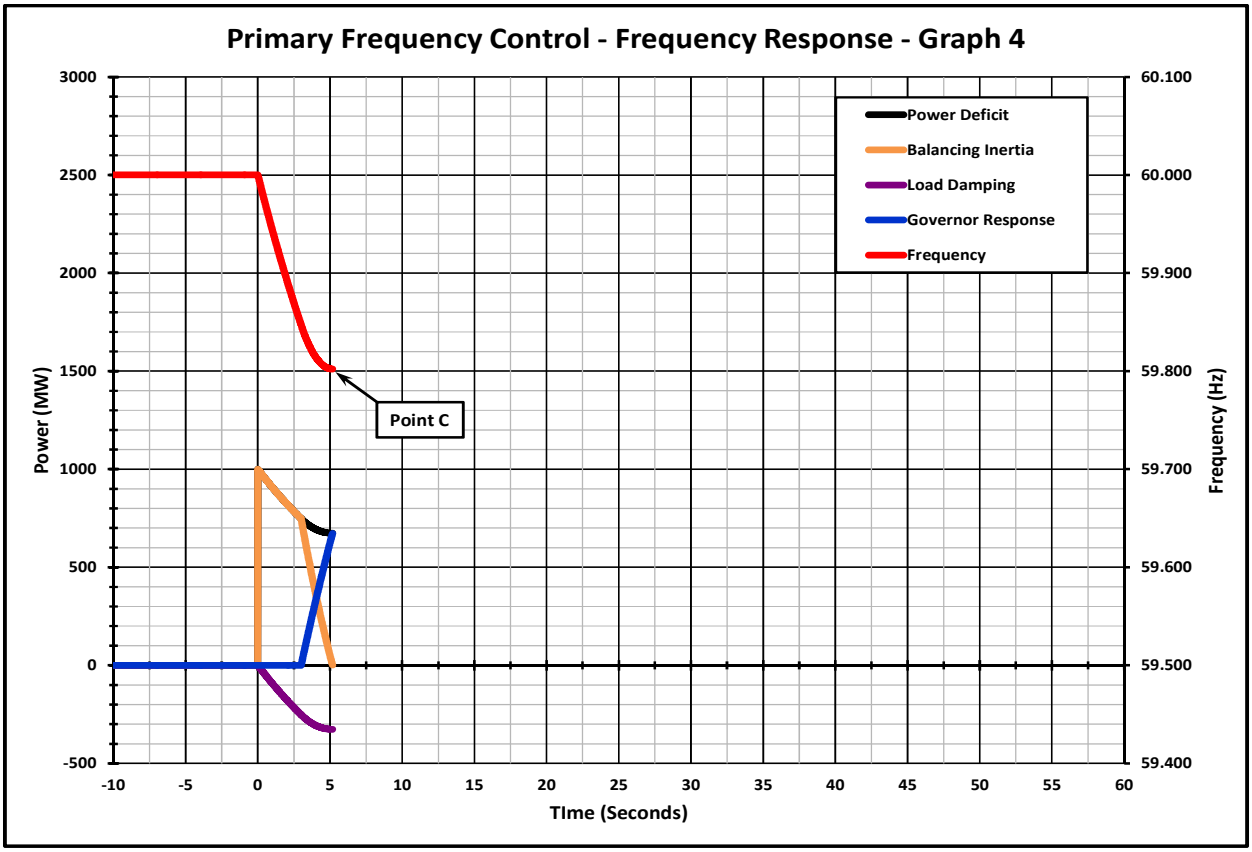
During the initial seconds of the Disturbance event, the governors have yet to respond to the frequency decline. This is illustrated with the Blue line on the third graph, Primary Frequency Control – Frequency Response – Graph 3, showing Governor Response. This time delay results from the time that it takes the controller to adjust the equipment and the time it takes the mass to flow from the source of the energy (main steam control valve for steam turbines, the combustor for gas turbines, or the gate valve for hydro turbines) to the turbine-generator blades where the power is converted to electrical energy.



Note that the frequency continues to decline due to the ongoing extraction by balancing inertia power of energy from the rotating turbine-generators and synchronous motors on the interconnection. The reduction in load also continues as the effect of load damping continues

to reduce the load while frequency declines. During this time delay (before the governor response begins) the balancing inertia limits the rate of change of frequency.

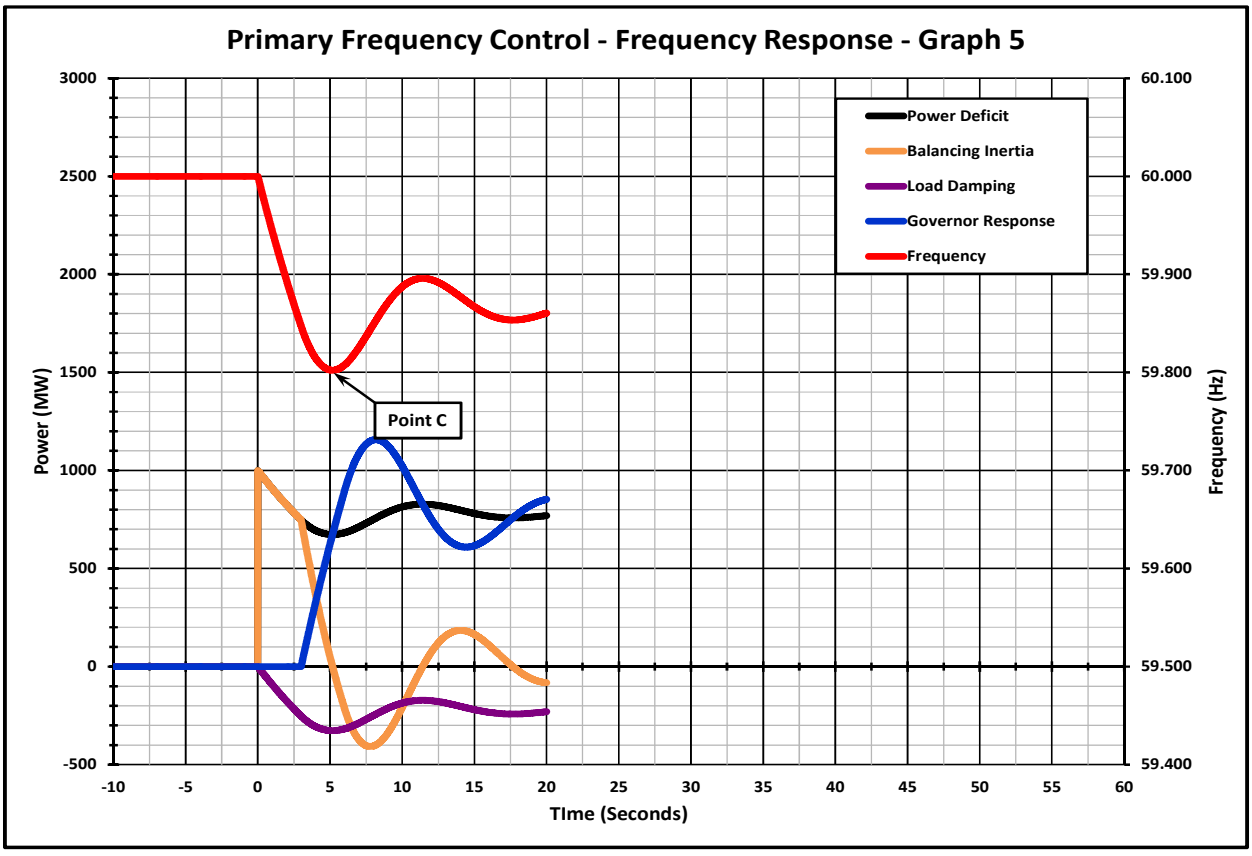
After a short time delay, the governor response begins to increase rapidly in response to the initial rapid decline in frequency, as illustrated on the fourth graph, Primary Frequency Control – Frequency Response – Graph 4. Governor response exactly offsets the power deficit at the point in time that the frequency decline is arrested. At this point in time, the balancing inertia has provided its contribution to reliability and its power contribution is reduced to zero as it is replaced by the governor response. If the time delay associated with the delivery of governor response is reduced, the amount of balancing inertia required to limit the change in frequency by the Disturbance event can also be reduced. This supports the conclusion that balancing inertia is required to manage the time delays associated with the delivery of Frequency Response. Not only is the rapid delivery of Frequency Response important, but the shortening of the time delay associated with its delivery is also important. Therefore, two important components of Frequency Response are 1) how long the time delay is before the initial delivery of response begins; and 2) how much of the response is delivered before the frequency change is arrested.



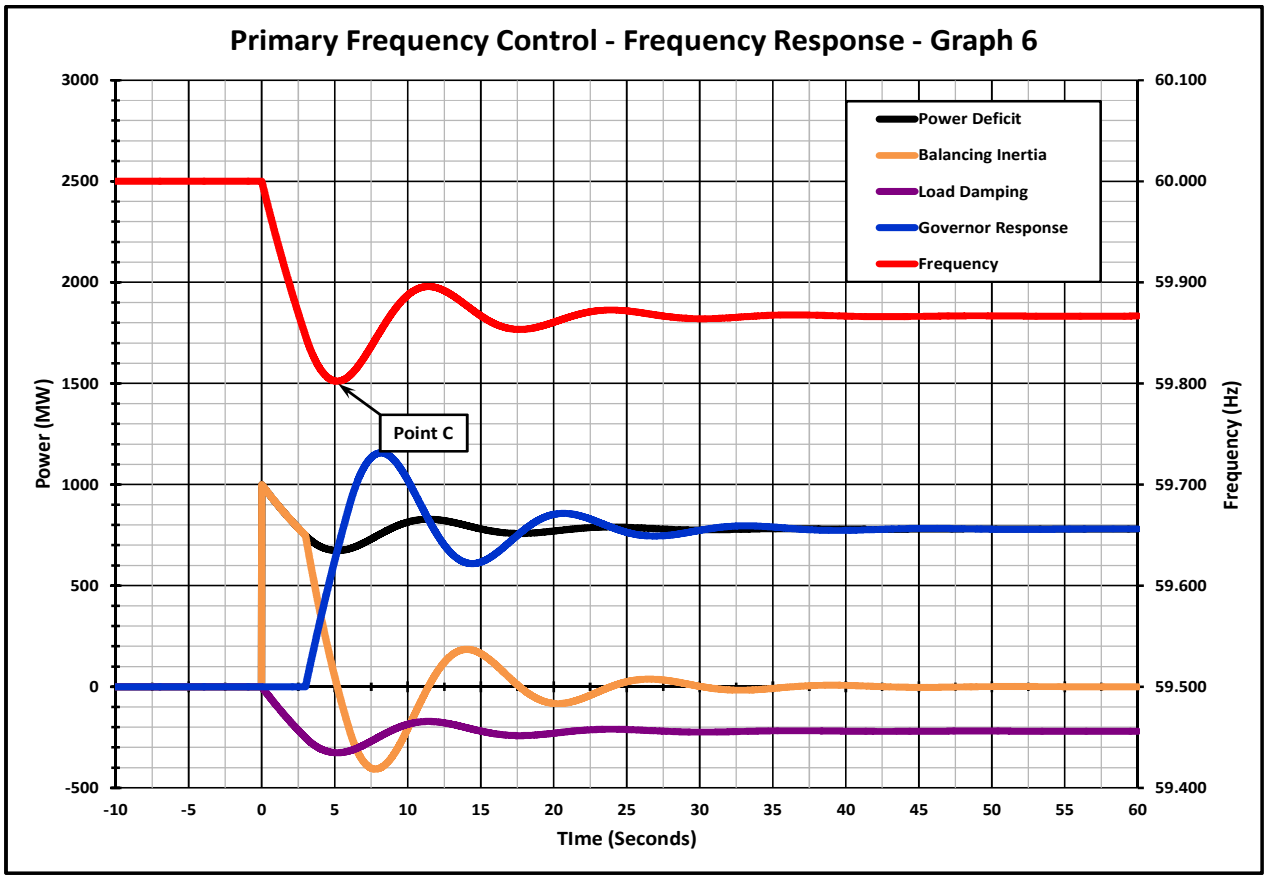
This point, at which the frequency is first arrested, is defined as "Point C" and Frequency Response calculated at this point is called the "**arrested frequency response**." The arrested frequency is normally the minimum (maximum for load loss events) frequency that will be

experienced during a Disturbance event. From a reliability perspective, this minimum frequency is the frequency that is of concern. Adequate reliability requires that frequency at the time frequency is arrested remain above the under-frequency relay settings so as not to trip these relays and the firm load interrupted by them. Frequency Response delivered after frequency is arrested at this minimum level provides less reliability value than Frequency Response delivered before Point C, but greater value than Secondary Frequency Control power and energy which is delivered minutes later.

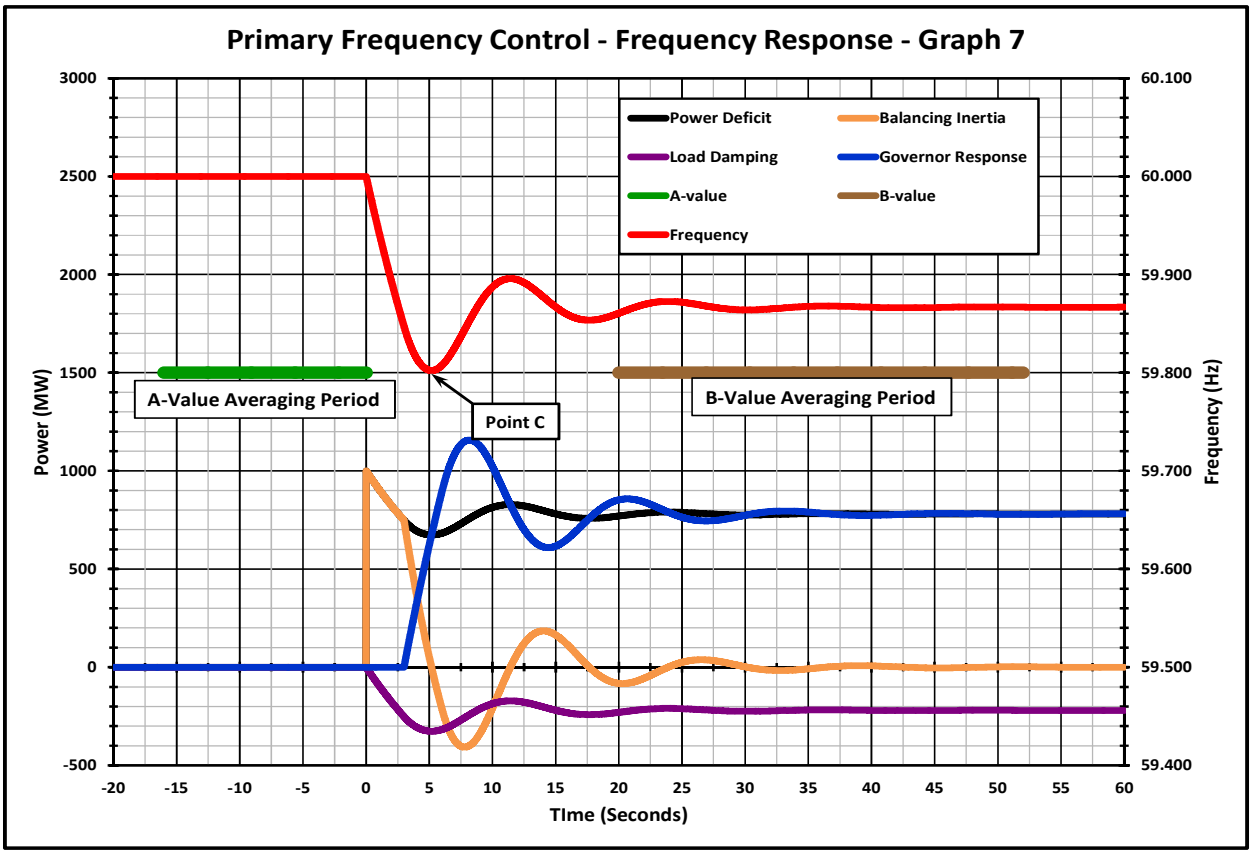
Once the frequency decline is arrested, the governors continue to respond because of the time delay associated with their Governor Response. This results in the frequency partially recovering from the minimum arrested value and results in an oscillating transient that follows the minimum frequency (arrested frequency) until power flows and frequency settle during the transient period that ends roughly 20 seconds after the Disturbance event. This post-disturbance transient period is included on the fifth illustrative graph, Primary Frequency Control – Frequency Response – Graph 5.



The total Disturbance event illustration is presented on the sixth graph, Primary Frequency Control – Frequency Response – Graph 6. Frequency and power contributions stabilize at the end of the transient period. Frequency Response calculated from data measured during this settled period is called the "Settled Frequency Response." The Settled Frequency Response is the best measure to use as an estimator for the "Frequency Bias Setting" discussed later.



The final Disturbance event illustration is presented on the seventh graph, Primary Frequency Control – Frequency Response – Graph 7. This graph shows the averaging periods used to estimate the pre-disturbance A-Value averaging period and the post-disturbance B-Value averaging period used to calculate the settled frequency response. A discussion of the measurement of Frequency Response immediately follows these graphs. That discussion includes consideration of the factors that affect the methods chosen to measure Frequency Response for implementation in a reliability standard.



Frequency Response Measurement (FRM)

The classic Frequency Response points A, C, and B, shown below in Fig. 1 Frequency Response Characteristic, are used for measurement as found in the Frequency Response Characteristic Survey Training Document within the NERC operating manual, found at http://www.nerc.com/files/opman_7-1-11.pdf. This traditional Frequency Response Measure has recently been more specifically termed "**settled frequency response**." This term has been used because it provides the best Frequency Response Measure to estimate the Frequency Bias Setting in Tie-line Bias Control based Automatic Generation Control Systems. However, the industry has recognized that there is considerable variability in measurement resulting from the selection of Point A and Point B in the traditional measure making the traditional measurement method unsuitable as the basis for an enforceable reliability standard in a real world setting of multiple Balancing Authority interconnections.

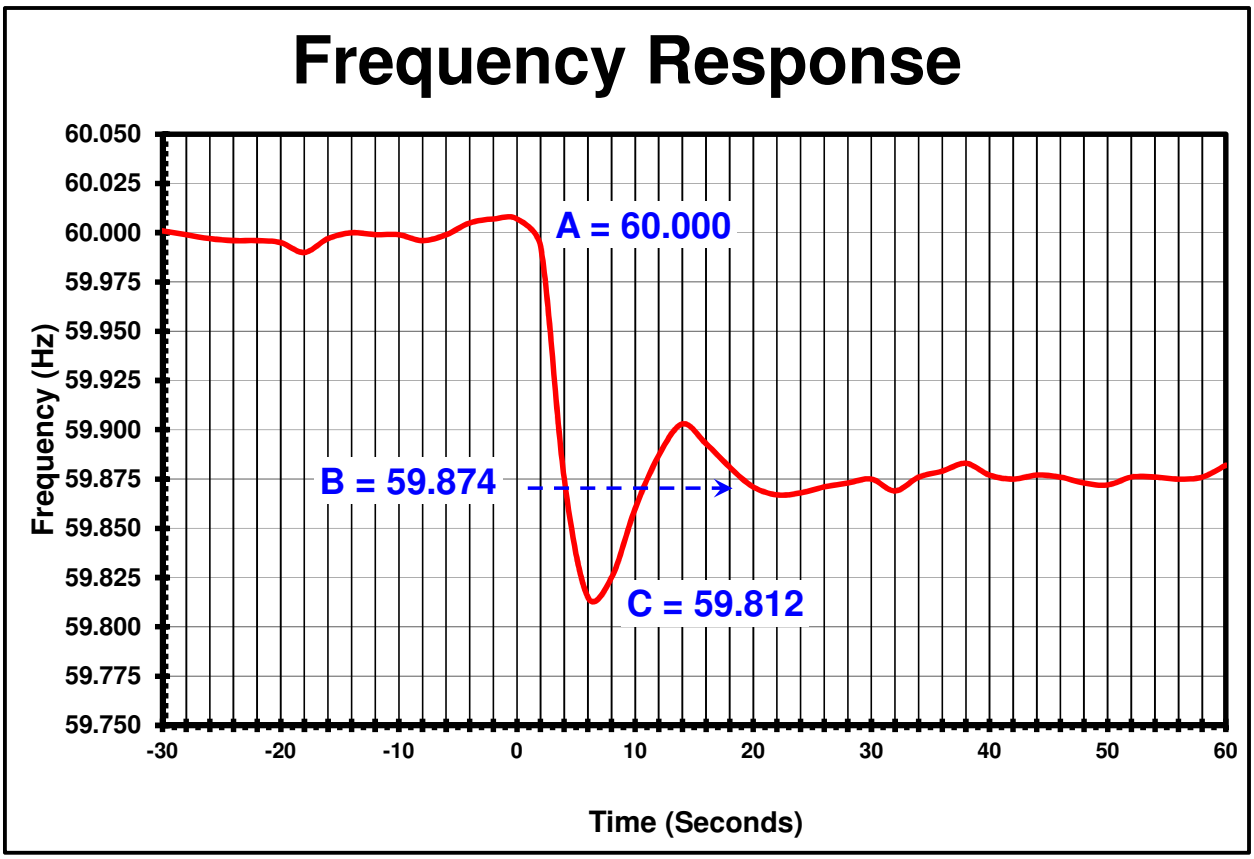


Figure 1. Frequency Response Characteristic

By contrast, measuring an Interconnection's settled frequency response is straightforward and fairly accurate. All that's needed to make the calculation is to know the size of a given contingency (MW), divide this value by the change in frequency and multiply the results by 10 since frequency response is expressed in MW/0.1Hz.

Measuring a BA's frequency response is more challenging. Prior to BAL-003-1, NERC's *Frequency Response Characteristic Survey Training Document* provided guidance to calculate Frequency Response. In short, it told the reader to identify the BA's interchange values "immediately before" and "immediately after" the Disturbance event and use the difference to calculate the MWs the BA deployed for the event. There are two challenges with this approach:

- Two people looking at the same data would come up with different values when assessing which exact points were immediately before and after the event.
- In practice, the actual response provided by the BA can change significantly in the window of time between point B and when secondary and tertiary control can assist in recovery.

Therefore, the measurement of settled frequency response has been standardized in a number of ways to limit the variability in measurement resulting from the poorly specified selection of Point A and Point B. It should be noted that t-0 has been defined as the first scan value that

shows a deviation in frequency of some significance, usually approaching about 10 mHz. The goal is such that the first scan prior to t-0 was unaffected by the deviation and appropriate for one of the averaging points.

- The A-value averaging period of approximately the previous 16 seconds prior to t-0 was selected to allow for an averaging of at least 2 scans for entities utilizing 6 second scan rates. (All time average period references in this document are for 2 second scan rates unless noted otherwise.)
- The B-value averaging period of approximately (t+20 to t+52 seconds) was selected to attempt to obtain the average of the data after primary frequency response was deployed and the transient completed(settled), but before significance influence of secondary control. Multiple periods were considered for averaging the B-value:
    - 12 to 24 sec
    - 18 to 30 sec
    - 20 to 40 sec
    - 18 to 52 sec
    - 20 to 52 sec

  It is necessary for all BAs from an interconnection to use the same averaging periods to provide consistent results. In addition, the SDT decided that until more experience is gained, it is also desirable for all interconnections to use the same averaging periods to allow comparison between interconnections.

The methods presented in this document only address the values required to calculate the frequency response associated with the frequency change between the initial frequency, A-Value, and the settling frequency, B-Value. No reasonable or consistent calculations can be made relating to the arresting frequency, C-Value, using Energy Management System (EMS) scan rate data as long as 6-seconds or tie-line flow values associated with the minimum value of the frequency response characteristic (C-value) as measured at the BA level.

Both the calculation of the frequency at Point A and the frequency at Point B began with the assumption that a 6-second scan rate was the source of the data. Once the averaging periods for a 6-second scan rate were selected, the averaging periods for the other scan rates were selected to provide as much consistency as possible between BAs with different scan rates.

The Frequency at Point A was initially defined as the average of the two scans immediately prior to the frequency event. All other averaging periods were selected to be as consistent as possible with this 12 second average scan from the 6-second scan rate method. In addition, the "**actual net interchange immediately before Disturbance**" is defined as the average of the same scans as used for the Point A frequency average.

The Frequency at Point B was then selected to be an average as long as the average of 6-second scan data as possible that would not begin until most of the hydro governor response had been delivered and would end before significant Automatic Generation Control (AGC) recovery response had been initiated as indicated by a consistent frequency restoration slope. The "**actual net interchange immediately after Disturbance**" is defined as the average of the same scans as used for the Point B frequency average.

B Averaging Period Selection:

Experience from the Electric Reliability Council of Texas ("ERCOT") and the field trail on other interconnections indicated that the 12 to 24 second and 18 to 30 second averaging periods were not suitable because they did not provide the consistency in results that the other averaging periods provided, and that the remaining measuring periods do not provide significantly different results from each other. The team believed that this was observed because the transients were not complete in all of the samples using these averaging periods.

The 18 to 52 second and 20 to 52 second averaging periods were compared to each other, with the 20 to 52 second period providing more consistent values, believed to result from the incomplete transient in some of the 18 to 52 second samples.

This left a choice between the 20 to 40 second and the 20 to 52 second averaging periods. The team recognized that there would be more AGC response in the 20 to 52 second period, but the team also recognized that the 20 to 52 second period would provide a better measure of squelched response from outer loop control action. The 20 to 52 second period was selected because it would indicate squelched response from outer-loop control and provide incentive to reduce response withdrawal. The final selections for the data averaging periods used in FRS Form 1 are shown in the table below.

Definitions of Frequency Values for Frequency Response Calculation

Scan Rate	T 0 Scan	A Value (average)	B Value (average)
6-Seconds	Identify first significant change in frequency as the T 0 scan	Average of T-1 through T-2 scans	Average of T+4 through T+8 scans
5-Seconds		Average of T-1 through T-2 scans	Average of T+5 through T+10 scans
4-Seconds		Average of T-1 through T-3 scans	Average of T+6 through T+12 scans
3-Seconds		Average of T-1 through T-5 scans	Average of T+7 through T+17 scans
2-Seconds		Average of T-1 through T-8 scans	Average of T+10 through T+26 scans

Consistent measurement of Primary Frequency Response is achievable for a selected number of events and can produce representative frequency response values, provided an appropriate sample size is used in the analysis. Available research investigating the minimum sample size to provide consistent measurements of Frequency Response has shown that a minimum sample size of 20 events should be adequate.

Measurement of Primary Frequency Response on an individual resource or load basis requires analysis of energy amounts that are often small and difficult to measure using current methods. In addition, the number of an interconnection's resources and loads providing their response could be problematic when compiling results for multiple events.

Measurement of Primary Frequency Response on an interconnection (System) basis is straight forward provided that an accurate frequency metering source is available and the magnitude of the resource/load imbalance is known in MWs.

Measurement on a Balancing Authority basis can be a challenge, since the determination of change in MWs is determined by the change in the individual BA's metered tie lines. Summation of tie lines is accomplished by summing the results of values obtained by the digital scanning of meters at intervals up to six seconds, resulting in a non-coincidental summing of values. Until the technology to GPS time stamp tie line values at the meter and the summing of those values for coincidental times is in use throughout the industry, it is necessary to use averaging of values described above to obtain consistent results.

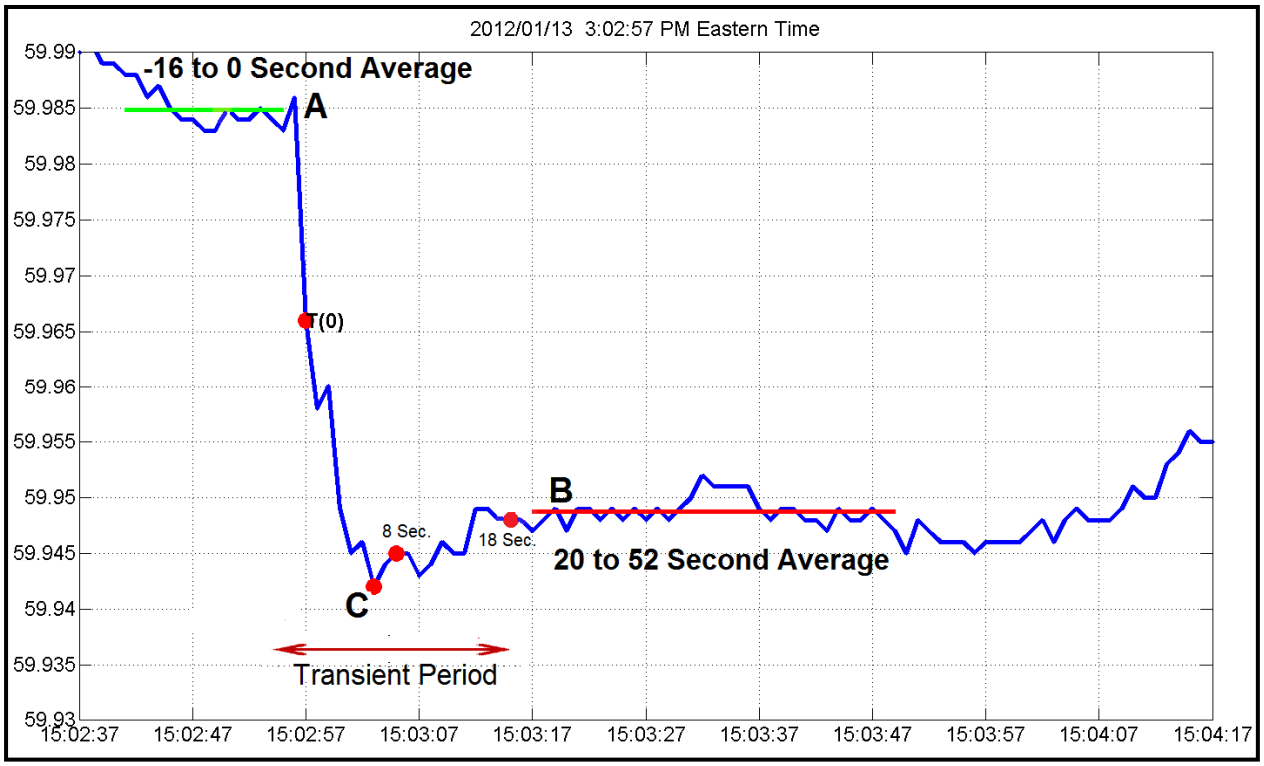

Figure 2. Frequency Response Measurement

The standardized measure is shown graphically in Fig. 2 Frequency Response Measurement with the averaging periods shown by the solid ~~blue~~ green and red lines on the graph. Since FERC directed a performance obligation for BAL-003-1, it is important to be more objective in the measurement process. The standardized calculation is available on FRS Form 2 for EMS scan rates of 2, 3, 4, 5, and 6 seconds at http://www.nerc.com/filez/standards/Frequency_Response.html.

Arrested Frequency Response

There is another measure of Frequency Response that is of interest when developing a Frequency Response estimate that not only will be used for estimating the Frequency Bias Setting, but will also be used to assure reliability by operating in a manner that will bound interconnection frequency and prevent the operation of Under-frequency Relays. This Frequency Response Measure has recently been named "**arrested frequency response.**" This Frequency Response is significantly affected by the inertial Frequency Response, the governor Frequency Response and the time delays associated with the delivery of governor Frequency

Response. It is calculated by using the change in frequency between the initial frequency, A, and the maximum frequency change during the event, C, instead of using the change between A and B. Arrested Frequency Response is the correct response for determining the minimum Frequency Response related to under-frequency relay operation and the support of interconnection reliability. This is because it can be used to provide a direct estimate of the maximum frequency deviation an interconnection will experience for an initial frequency and a given size event in MW. Unfortunately, arrested frequency response cannot currently be measured using the existing EMS-based measurement infrastructure. This limitation exists because the scan rates currently used in industry EMSs are incapable of measuring the net actual interchange at the same instant that the maximum frequency deviation is reached. Fortunately, the ratio of arrested frequency response and settled frequency response tends to be stable on an interconnection. This allows the settled frequency response value to be used as a surrogate for the arrested frequency response and implement a reasonable measure upon which to base a standard. One consequence of using the settled frequency response as a surrogate for the arrested frequency response is the inclusion of a large reliability margin in Interconnection Frequency Response Obligation to allow for the difference between the settled frequency response as measured and the arrested frequency response that indicates reliability.

As measurement infrastructure improves one might expect the Frequency Response Obligation to transition to a measurement based directly on the arrested frequency response while the Frequency Bias Setting will continue to be based on the settled frequency response. However, at this time, the measurement devices and methods in use do not support the necessary level of accuracy to estimate arrested frequency response contribution for an individual Balancing Authority.

Frequency Response Definition and Examples

Limitations of the measurement infrastructure determine the measurement methods recommended in this standard. The measurement limitations provide opportunities to improve the Frequency Response as measured in the standard without contributing to an improvement in Frequency Response that contributes to reliability. These definitions and examples provide a basis for determining which contributions to Frequency Response contribute the most to improved reliability. They also provide the basis for determining on a case by case basis whether the individual contributors to the Frequency Response Measure are also contributing to reliability.

General Frequency Response Characteristics

In the simplest case Frequency Response includes any automatic response to changes in local frequency. If that response works to decrease that change in frequency, it is beneficial to reliability. If that response works to increase that change in frequency, it is detrimental to reliability. However, this definition does not address the relative value of one response as compared to other responses that may be provided in a specific case.

There are numerous characteristics associated with the Frequency Response that affect the reliability value and economic value of the response. These characteristics include:

1. **Inertial** – the response is inertial or approximates inertial response

Inertial response provides power without delay that is proportional to the frequency and the change in frequency. Therefore, power provided by electronic control as synthetic Inertial response must be proportional to the frequency and change in frequency and be provided without a time delay.

2. **Immediate** – no unnecessary intentional time delays or reduction in the rate of response delivery
    a. time delay before the beginning of the response
    Turbines that convert heat or kinetic energy have time delays related to the time delay from the time that the control valves are moved to initiate the change in power and the time that the power is delivered to the generator. These times are usually associated with the time it takes a change in mass flow to travel from the control valve to the first blades of the turbine in the turbine generator.

    b. reduction in the rate of response delivery
    There are natural delays associated with the rate of response delivery that are related to the mass flow travel from the first turbine blades to the last turbine blades. In addition, some turbines have intentional delays designed into the control system to slow the rate of change in the delivery of the kinetic energy or fuel to the turbine to prevent the turbine or other equipment from being damaged, hydro turbines, or to prevent the turbine from tripping due to excessive rate of change, gas turbines.

3. **Proportional** – the amount of the total response is proportional to the frequency error
    a. No Deadband – the response is proportional across the entire frequency range
    b. Deadband – the response is only proportional outside of a defined deadband

4. **Bi-directional** – the response occurs to both increases and decreases in frequency

5. **Continuous** – there are no discontinuities in the delivery of the response (no step changes)

6. **Sustained** – the response is sustained until frequency is returned to schedule

Frequency Response Reliability Value

This section contains a more detailed discussion of the various characteristics of Frequency Response listed in the previous section. It also provides an indication of the relative value of these characteristics with respect to their contribution to reliability. Finally, it includes some examples of the described responses.

Inertial Response is provided from the stored energy in the rotating mass of the turbine-generators and synchronous motors on the interconnection. It limits the rate of change of frequency until sufficient Frequency Response can be supplied to arrest the change in frequency. Its reliability value increases as the time delay associated with the delivery of other Frequency Response on the interconnection increases. If those time delays are minimal, then the value of inertial response is low. If all time delays associated with the Frequency Response could be eliminated, then inertial response would have little value.

The reliability value of Inertial Response is the greatest on small interconnections because the size of the Disturbance events is larger relative to the inertia of the interconnection. Electronic controls have been developed to provide synthetic inertial response from the stored energy in asynchronous generators to supplement the natural inertial response. Some Type III & IV Wind Turbines have this capability. In addition, electronically controlled SCRs have been developed that can store energy in the electrical system and release this stored energy to supply synthetic inertial response when required.

Immediate Response is provided by load damping and because the time delays associated with its delivery are very short (related to the speed of electrical signal in the electrical system); load damping requires very little inertial response to limit arrested frequency effectively. Synthetic immediate response can also be supplied from loads because in many cases, there is no mass flow time delay associated with the load process providing the power and energy reduction. Therefore, loads can provide an immediate response with a higher reliability value than generators with time delays required by the physics of the turbine-generator.

Governor response has time delays associated with its delivery. Governor response provided with shorter time delays has a higher reliability value because those shorter time delays require less inertial response to arrest frequency. Governor response is provided by the turbine-generators on the interconnection. Time delays associated with governor response vary depending on the type of turbine-generator providing the response.

The longest time delays are usually associated with high head hydro turbine-generators that require long times from the governor action until the additional mass flow through the turbine. These units may also have the longest delivery time associated with the full delivery of response because of the timing designed into the governor response.[5]

Intermediate time delays are usually associated with steam turbine-generators. The response begins when the steam control valves are adjusted and the steam mass flows from the valves to the first high pressure turbine blades. The delivery times associated with the full delivery of response may require the steam to flow through high, intermediate and low pressure turbines including reheat flows before full power is delivered. These times are shorter than those of the hydro turbine-generators in general, but not as fast as the times associated with gas turbines.[6]

Gas turbines typically have the shortest time delays, because control is provided by injecting more or less fuel into the turbine combustor and adjusting the air control dampers. These control changes can be initiated rapidly and the mass flow has the shortest path to the turbine

[5] Interconnected Power System Response to Generation Governing: Present Practice and Outstanding Concerns – Final Report, IEEE, May 2007, pp. 1-6 – 1-9.

[6] Interconnected Power System Response to Generation Governing: Present Practice and Outstanding Concerns – Final Report, IEEE, May 2007, pp. 1-4 – 1-6.

blades. There may be timing limitations related to the rate of change in output of the gas turbine-generator to maintain flame stability in some cases slowing the rate of change.[7]

Synthetic Governor Response can be supplied by certain loads and storage systems. The immediacy of the response is normally limited only by the electronic controls used to activate the desired response. Synthetic response, when it can be supplied immediately without significant time delay, has a higher reliability value because it requires less inertial response to achieve smaller arrested frequency deviations.

Proportional Response indicates that the response provided is proportional in magnitude to the frequency error. Response deadbands cause a non-proportional response and reduce the value of the response with respect to reliability. Contrary to general consensus, deadbands do not reduce the amount of Frequency Response that must be provided, they only transfer the responsibility for providing that Frequency Response from one source on the interconnection to another. For a given response, the response with the smaller deadband has the greater reliability value. Therefore, deadbands should be set to the smallest value that supports overall reliable operation including the reliable operation of the generator.

Electronic controls have also been developed to provide synthetic governor response. When these controls are applied to certain loads or stored energy systems, they can be programmed to provide synthetic governor response similar to the proportional response of a turbine-generator governor. Governor response in generators is limited to a small percentage of the output of the generating unit, while synthetic governor response could be applied to much larger percentages of loads or storage devices providing such response.

Load damping provides a proportional response.

Continuous Response is response that has no discontinuous (step) changes in the frequency versus response curve. Step changes (Non-continuous Response) in the Governor Response curve can lead to frequency instabilities at frequencies near the changes. The ERCOT Interconnection observed this and has since prohibited the use of governor response characteristics incorporating step responses.

Step responses also occur with the implementation of load interruption using under-frequency or over-frequency relays.

Bi-directional Response is response that occurs in both directions, when the frequency is increasing and when the frequency is decreasing. A uni-directional response is a response that only occurs once when frequency is decreasing or when frequency is increasing.

Inertial response, governor response and load damping are all bi-directional responses. Certain loads are capable of providing proportional bi-directional response while others are only capable of providing non-proportional bi-directional response.

[7] Interconnected Power System Response to Generation Governing: Present Practice and Outstanding Concerns – Final Report, IEEE, May 2007, pp. 1-16 – 1-19.

The ERCOT Load Resource program is a uni-directional response program. Loads are only tripped when frequency declines below a given set-point. When frequency is restored above that set-point, the loads must be manually reconnected. As a consequence, the Frequency Response only occurs once with declining frequency and does not oppose the increase in frequency after the initial decline. If there should be a frequency oscillation, the uni-directional response will not contribute to the opposition of a second frequency decline across the set-point during an oscillation event. Once a uni-directional response has occurred, it is unavailable for a second decline before reset.

Step or proportional responses implemented bi-directionally can lead to frequency instability when there is less continuous frequency response than the magnitude of the change in continuous response between the trip and reset frequencies in step, or the proportional response rate of change is greater than the underlying continuous response. A step bi-directional response will have the load reconnected as frequency recovers from the event thus opposing the increase in frequency during recovery, and also resetting the load response for the next frequency decline automatically. Bi-directional response obviously has a greater reliability value than uni-directional response.

Sustained Response is provided at its full value until frequency is restored to its scheduled value. On today's interconnections, few frequency responses are fully sustained until frequency has been restored to its scheduled value. On steam based turbine-generators, the steam pressure may drop after a time as the result of the additional steam flow from governor action. However, in general this has not been a problem because most responses are incomplete at the time that frequency has been initially arrested and the additional response has generally been sufficient to make up for more than the these unpreventable reductions in response. However, the intentional withdrawal of response before frequency has been restored to schedule can cause a decline in frequency beyond that which would be otherwise expected. This intentional withdrawal of response is highly detrimental to reliability. Therefore, it can be concluded in general that sustained response has a higher reliability value than un-sustained response.

On an interconnection, the withdrawal of response due to the loss of steam pressure on the steam units may be offset by the slower response of hydro turbine-generators. In these cases, the reliability of the combined response provides a greater reliability value than the individual response of each type. The steam turbine-generators provide a fast response that may be reduced, while the hydro turbine-generators provide a slower response, contributing less to the arresting response, offsetting any reduction by the steam turbine-generators to assure a sustained response.

Sustained Response must also be considered for any resource that has a limited duration associated with its response. The amount of stored energy available from a resource may limit its ability to sustain response for a duration of time necessary to support reliability.

Frequency Response Cost Factors

In every system of exchange there are two sides; the supply side and the demand side. The supply side provides the services used by the demand side. In the case of Frequency Response,

the supply side includes all providers of Frequency Response and the demand side includes all participants that create the need for Frequency Response.

Frequency Response Costs – Supply Side

There are a number of factors that affect the cost of providing Frequency Response from resources. Since there is a cost associated with those factors, some method of appropriate compensation could be made available to those resources providing Frequency Response. Without compensation, providers of Frequency Response will be put in the position of incurring additional cost that can be avoided only by reducing or eliminating the response they provide. These costs are incurred independently of whether provided for in a formal Regional Transmission Organization/Independent System Operator (RTO/ISO) market or in a traditional BA subject to the FERC pro-forma tariffs.

It is the responsibility of the BA or the RTO/ISO to acquire the necessary amount of Frequency Response to support reliability in the most cost effective manner. This function is performed best when the suppliers are evaluated based on the value of the Frequency Response they provide and compensated appropriately for that Frequency Response. Suppliers provide Frequency Response when they are assured that they will receive fair compensation. Before considering how to perform this evaluation and compensation, the costs associated with providing Frequency Response should be understood and evaluated with respect to the level of reliability they offer.

Some cost factors that have been identified for providing Frequency Response include:

1. **Capacity Opportunity Cost** – the costs, including opportunity costs, associated with reserving capacity to provide Frequency Response. These costs are usually associated with the alternative use of the same capacity to provide energy or other ancillary services. There may also be capacity opportunity costs associated with the loss in average capacity by a load providing Frequency Response.
2. **Fuel Cost** – The cost of fuel used to provide the Frequency Response. The costs for fuel to provide Frequency Response can result in energy costs significantly different from the system marginal energy cost, both higher and lower. This is the case when Frequency Response is provided by resources that are not at the system marginal cost.
3. **Energy Efficiency Penalty Costs** – the costs associated with the loss in efficiency when the resource is operated in a mode that supports the delivery of Frequency Response. This cost is usually in the form of additional fuel use to provide the same amount of energy. An example is the difference between operating a steam turbine in valve control mode with an active governor and sliding pressure mode with valves wide open and no active governor control except for over-speed. This cost is incurred for all of the energy provided by the resource, not just the energy provided for Frequency Response. There may be additional energy costs associated with a load providing Frequency Response from loss in efficiency of their process when load is reduced.
4. **Capacity Efficiency Penalty Costs** – the costs associated with any reduction in capacity resulting from the loss of capacity associated with the loss in energy efficiency. When efficiency is lost, capacity may be lost at the same time because of limitations in the amount of input energy that can be provided to the resource.

5. **Maintenance Costs** – the operation of the resource in a manner necessary to provide Frequency Response may result in increases in the maintenance costs associated with the resource.
6. **Emissions Costs** – the additional costs incurred to manage any additional emissions that result when the resource is providing Frequency Response or stands ready to provide Frequency Response.

A good contract for the acquisition of Frequency Response from a resource will provide appropriate compensation to the resource for all of the costs the resource incurs to provide Frequency Response. It will also provide a method to evaluate the least cost mix of resources necessary to provide the minimum required Frequency Response for maintaining reliability. Finally, it will provide the least complex method of evaluation considering the complexity and efficiency of the acquisition process.

Frequency Response Costs – Demand Side

Not only are there costs associated with acquiring Frequency Response from the supplying resources, there are costs associated with the amount of Frequency Response that must be acquired and influenced by those participants that create the need for Frequency Response. If the costs of acquiring Frequency Response from the supply resources can be assigned to those parties that create the need for Frequency Response, there is the promise that the amount of Frequency Response required to maintain reliability can be minimized. The considerations are the same as those that are driving the development of "real time pricing" and "dynamic pricing". If the costs are passed on to those contributing to the need for Frequency Response, incentives are created to reduce the need for Frequency Response making interconnection operations less expensive and more reliable. The problem is to balance both cost and complexity against reliability on both the supply side and the demand side.

Rationale by Requirement

Requirement 1

R1. Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or Balancing Authority that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation.

Background and Rationale

R1 is intended to meet the following primary objectives:

- Determine whether a Balancing Authority (BA) has sufficient Frequency Response for reliable operations.
- Provide the feeder information needed to calculate CPS limits and Frequency Bias Settings.

Primary Objective

With regard to the first objective, FRS Form 1 and the process in Attachment A provide the method for determining the Interconnections' necessary amount of Frequency Response and allocating it to the Balancing Authorities. The field trial for BAL-003-1 is testing an allocation methodology based on the amount of load and generation in the BA. This is to accommodate the wide spectrum of BAs from generation-only all the way to load-only.

Frequency Response Sharing Groups (FRSGs)

This standard proposes an entity called FRSG, which is defined as:

> *A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.*

This standard allows Balancing Authorities to cooperatively form FRSGs as a means to jointly meet the FRS. There is no obligation to form or be a part of FRSGs. The members of the FRSG would determine how to allocate sanctions among its members. This standard does not mandate the formation of FRSGs, but allows them as a means to meet one of FERC's Order No. 693 directives.

FRSG performance may be calculated one of two ways:

- Calculate a group NI_A and measure the group response to all events in the reporting year on a single FRS Form 1, or
- Jointly submit the individual BAs' Form 1s, with a summary spreadsheet that sums each participant's individual event performance.

Frequency Response Obligation and Calculation

The basic Frequency Response Obligation is based on annual load~~non-coincident peak load~~ and generation data reported in FERC Form 714 (where applicable, see below for non-jurisdictional entities) for the previous full calendar year. The basic allocation formula used by NERC is:

$$\mathrm{FRO_{BA}} = \mathrm{FRO_{Int}} \times \frac{\text{Annual Gen}_{\mathrm{BA}} + \text{Annual Load}_{\mathrm{BA}}}{\text{Annual Gen}_{\mathrm{Int}} + \text{Annual Load}_{\mathrm{Int}}}$$

Where:

- Annual $\mathrm{Gen_{BA}}$ is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
- Annual $\mathrm{Load_{BA}}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
- Annual $\mathrm{Gen_{Int}}$ is the sum of all Annual $\mathrm{Gen_{BA}}$ values reported in that interconnection.
- Annual $\mathrm{Load_{Int}}$ is the sum of all Annual $\mathrm{Load_{BA}}$ values reported in that interconnection.

Balancing Authorities that are not FERC jurisdictional should use the Form 714 Instructions to assemble and submit equivalent data. Until the BAL-003-1 process outlined in Attachment 1 is implemented, Balancing Authorities can approximate their FRO by multiplying their Interconnection's FRO by their share of Interconnection Bias. The data used for this calculation should be for the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which utilized data from 2011.

Balancing Authorities that merge or that transfer load or generation need to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation for the Interconnection remains the same and so that CPS limits can be adjusted.

Attachment A proposes the following Interconnection event criteria as a basis to determine an Interconnection's Frequency Response Obligation:

- Largest category C loss-of-resource (N-2) event.
- Largest total generating plant with common voltage switchyard.
- Largest loss of generation in the interconnection in the last 10 years.

With regard to the second objective above (determining Frequency Bias Settings and CPS limits), Balancing Authorities have been asked to perform annual reviews of their Frequency Bias Settings by measuring their Frequency Response, dating back to Policy 1. This obligation was carried forward into BAL-003-01.b. While the associated training document provided useful information, it left many of the details to the judgment of the person doing the analysis. The FRS Form 1 and FRS Form 2 provide a consistent, objective process for calculating Frequency Response to develop an annual measure, the FRM.

The FRM will be computed from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz". The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change of its net actual interchange on its tie lines with its adjacent Balancing Authorities divided by the change in interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their net actual interchange values to account for factors such as nonconforming loads. FRS Form 1 shows the types of adjustments that are allowed.)

A standardized sampling interval of approximately 20 to 52 seconds will be used in the computation of SEFRD values. Microsoft Excel® spreadsheet interfaces for EMS scan rates of 2 through 6 seconds are provided to support the computation.

Single Event Frequency Response Data[8]

The use of a "single event measure" was considered early in the development of the FRS for compliance because a single event measure could be enforced for each event on the interconnection making compliance enforcement a simpler process. The variability of the measurement of Frequency Response for an individual BA for an individual Disturbance event was evaluated to determine its suitability for use as a compliance measure. The individual Disturbance events were normalized and plotted for each BA on the Eastern and Western Interconnections. This data was plotted with a dot representing each event. Events with a measured Frequency Response above the FRO were shown as blue dots and events with a measured Frequency Response below the FRO were shown as red dots. In order to show the full variability of the results the plots have been provided with two scales, a large scale to show all of the events and small scale to show the events closer to the FRO or a value of 1.0. This data is presented on four charts titled Frequency Response Events as Normalized by FRO.

Analysis of this data indicates a single event based compliance measure is unsuitable for compliance evaluation when the data has the large degree of variability shown in these charts. Based on the field trial data provided, only 3 out of 19 BAs on the Western Interconnection would be compliant for all events with a standard based on a single event measure. Only 1 out of 31 BAs on the Eastern Interconnection would be compliant for all events with a standard based on a single event measure. The general consensus of the industry is that there is not a reliability issue with insufficient Frequency Response on any of the North American Interconnections at this time. Therefore, it is unreasonable to even consider a standard that would indicate over 90% of the BAs in North American to be non-compliant with respect to maintaining sufficient Frequency Response to maintain adequate reliability.

In an attempt to balance the workload of Balancing Authorities with the need for accuracy in the FRM, the standard will require at least 20 samples selected during the course of the year to compute the FRM. Research conducted by the FRSDT indicated that a Balancing Authority's FRM will converge to a reasonably stable value with at least 20 samples.

Balancing Authority

Sample Size

In order to support field trial evaluations of sample size, sampling intervals, and aggregation techniques, the FRSDT will be retrieving scan rate data from the Balancing Authorities for each SEFRD. Additional frequency events may also be requested for research purposes, though they will not be included in the FRM computation.

FERC Order No. 693 directed the ERO (at P 375) to define the number of Frequency Response surveys that were conducted each year and to define a necessary amount of Frequency Response. R1 addresses both of these directives:

- There is a single annual survey of at least 20 events each year.
- The FRM calculated on FRS Form 1 is compared by the ERO against the FRO determined 12 months earlier (when the last FRS Form 1 was submitted) to verify the Balancing Authority provided its share of Interconnection Frequency Response.

Median as the Standard's Measure of Balancing Authority Performance

The FRSDT evaluated different approaches for "averaging" individual event observations to compute a technically sound estimate of Frequency Response Measure. The MW contribution for a single BA in a multi-BA Interconnection is small compared to the minute to minute changes in load, interchange and generation. For example, a 3000 MW BA in the ~~east~~ Eastern Interconnection may only be called on to contribute 10MW for the loss of a 1000MW. The 10 MW of governor and load response may easily be masked as a coincident change in load.

In general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FRSDT has shown the Median to be less influenced by noise in the measurement process and the team has chosen the median as the initial metric for calculating the BAs' Frequency Response Measure.

The FRSDT performed extensive empirical studies and engaged in lively discussions in an attempt to determine the best aggregation technique for a sample set size of at least 20 events. Mean, median, and linear regression techniques were used on a trial basis with the data that was available during the early phases of the effort.

A key characteristic of the "aggregation challenge" is related to the use of actual net interchange data for measuring frequency response. The tie line flow measurements are varying continuously due to other operational phenomena occurring concurrently with the provision of frequency response. (*See* Appendix 1 for details.) All samples have "noise" in them, as most operational personnel who have computed the frequency response of their BA can attest. What has also become apparent to the FRSDT is that while the majority of the frequency response samples have similar levels of noise in them, a few of the samples may have much larger errors in them than the others that result in unrepresentative results. And with the sample set size of interest, it is common to have unrepresentative errors in these few samples to be very large and asymmetric. For example, one BA's subject matter expert observed recently that 4 out of 31 samples had a much larger error contribution than the other 27 samples, and that 3 out of 4 of the very high error samples grossly underestimated the frequency response. The median value demonstrated greater resiliency to this data quality problem than the mean with this data set. (The median has also demonstrated superiority to

linear regression in the presence of these described data quality problems in other analyses conducted by the FRSDT, but the linear regression showed better performance than the mean.)

The above can be demonstrated with a relatively simple example. Let's assume that a Balancing Authority's true frequency response has an average value of -200 MW/ .1 Hz. Let's also assume that this Balancing Authority installed "special" perfect metering on key loads and generators, so that we could know the true frequency response of each sample. And then we will compare them with that measured by typical tie line flow metering, with the kind of noise and error that occurs commonly and "not so commonly". Let's start with the following 4 samples having a common level of noise, with MW/ .1 Hz as the unit of measurement.

Perfect measurement	Noise	Samples from tie lines
-190	-30	-220
-210	-20	-230
-220	10	-210
-180	20	-160
-200	Mean	-205
-200	Median	-215

Now let's add a fifth sample, which is highly contaminated with noise and error that grossly underestimates frequency response.

Perfect measurement	Noise	Samples from tie lines
-190	-30	-220
-210	-20	-230
-220	10	-210
-180	20	-160
-200	250	+50
-200	Mean	-154
-200	Median	-210

It is clear from the above simplistic example that the mean drops by about 25% while the median is affected minimally by the single highly contaminated value.

Based on the analyses performed thus far, the FRSDT believes that the median's superior resiliency to this type of data quality problem makes it the best aggregation technique at this time. However, the FRSDT sees merit and promise in future research with sample filtering combined with a technique such as linear regression.

When compared with the mean, linear regression shows superior performance with respect to the elimination of noise because the measured data is weighted by the size of the frequency change associated with the event. Since the noise is independent from frequency change, the greater weighting on larger events provides a superior technique for reducing the effect of noise on the results.

However, linear regression does not provide a better method when dealing with a few samples with large magnitudes of noise and unrepresentative error. There are only two alternatives to improve over the use of median when dealing with these larger unrepresentative errors:

1. Increase the sample size, or
2. Actively eliminate outliers due to unrepresentative error.

Unfortunately, the first alternative, increasing the sample size is not available because significantly more sample events are not available within the measurement time period of one year. Linear regression techniques are being investigated that have an active outlier elimination algorithm that would eliminate data that lie outside ranges of the 96th percentile and 99th percentile, for example.

Still, the use of linear regression has value in the context of this standard. The NERC Resources Subcommittee will use linear regression to evaluate Interconnection frequency response, particularly to evaluate trends, seasonal impacts, time of day influences, etc. The Good Practices and Tools section of this document outlines how a BA can use linear regression to develop a predictive tool for its operators.

Additional discussion on this topic is contained in "Appendix 1 – Data Quality Concerns Related to the Use of Actual Net Interchange Value" of this document.

The NERC Frequency Response Initiative Report addressed the relative merits of using the median versus linear regression for aggregating single event frequency response samples into a frequency response measurement score for compliance evaluation. This report provided 11 evaluation criteria as a basis for recommending the use of linear regression instead of the median for the frequency response measurement aggregation technique. The FRSDT made its own assessment on the basis of these evaluation criteria on September 20, 2012, but concluded that the median would be the best aggregation technique to use initially when the relative importance of each criterion was considered. A brief summary of the FRSDT majority consensus on the basis of each evaluation criterion is provided below.

- Provides two dimensional measurement – The FRSDT agrees that the two dimensional concept is a useful way to perceive frequency response characteristics, and that it may be useful for potential future modeling activities. Better data quality would increase support for such future efforts, and the use of the median for initial compliance evaluations within BAL-003-1 should not hinder any such effort. The FRSDT perceived this as a mild advantage for linear regression.
- Represents nonlinear characteristics – With considerations similar to those applied to the previous criterion, the FRSDT perceived this as a mild advantage for linear regression.
- Provides a single best estimator – The FRSDT ~~put~~ gave minimal importance to the characteristic of the median averaging the middle values when used with an even number of samples.
- Is part of a linear system - With considerations similar to those applied to the first two criteria, the FRSDT perceived this as a mild advantage for linear regression (particularly in the modeling area.)
- Represents bimodal distributions – The FRSDT ~~put~~ gave minimal weight of this criterion, as a change in Balancing Authority footprint does not seem to be addressed adequately by any aggregation technique.
- Quality statistics available – The FRSDT perceived this as a mild advantage for linear regression in that the statistics would be coupled directly to the compliance evaluation. The FRSDT also included this criterion as part of the modeling advantages cited above.

The FRSDT supports collecting data and performing quality statistical analysis. If it is determined that the use of the median, as opposed to a mean or linear regression aggregation, is yielding undesirable consequences, the FRSDT recommends that other aggregation techniques be re-evaluated at that time.

- Reducing influence of noise - This is the dominant concern of the FRSDT, and it perceives the median to have a major advantage over linear regression in addressing noise in the change in actual net interchange calculation. The FRSDT bases this judgment on: prior FRSDT studies that have shown that the median produces more stable results; the data used in the NERC Frequency Response Initiative document exhibits large quantities of noise; prior efforts of FRSDT members in performing frequency response sampling for their own Balancing Authorities over many years; and similar observations of noise in the CERTS frequency Monitoring Application. The FRSDT has serious concerns that the influence of noise has a greater tendency to yield a "false positive" compliance violation with linear regression than with the median. Also, limited studies performed by the FRSDT indicates the possibility that the resultant frequency response measure would yield more measurement variation across years with linear regression versus the median while the actual Balancing Authority performance remains unchanged.
- Reducing the influence of outliers – This is related to the previous criterion. The FRSDT recognizes four main sources of noise: concurrent operating phenomena (described elsewhere in this document), transient tie line flows for nearby contingencies, data acquisition time skew in tie line data measurements, and time skew and data compression issues in archiving techniques and tools such as PI. Some outliers may be caused in part by true variation in the actual frequency response, and it is desirable to include those in the frequency response measure. The FRSDT supports efforts in the near future to distinguish between outliers caused by noise versus true frequency response, and progress in this area may make it feasible and desirable to replace the median with linear regression, or some other validated technique. The FRSDT does note that this is a substantial undertaking, and it would require substantial input from a sufficient number of experts to help distinguish noise from true frequency response.
- Easy to calculate – The FRSDT perceives this to be a minor to moderate advantage for the median. However, more complex (but reasonably so) techniques would receive more support if clear progress can be made in noise elimination.
- Familiar indicator – The FRSDT perceives this to be a minor to moderate advantage for the median. However, more complex (but reasonably so) techniques would receive more support if clear progress can be made as a result of noise elimination.
- Currently used as a measure in BAL-003 – The present standard refers to an average and does not provide specific guidance on the computation of that average, but the FRSDT puts minimal weight on this evaluation criterion.

In summary, the FRSDT perceives an approximate balance between the modeling advantage for linear regression and the simplicity advantage of the median. However, the clear determinant in endorsing the use of the median is the data quality issue related to concurrent operational phenomena, transient tie line flows, and data acquisition and archiving limitations.

FERC Order No. 693 also directed the Standard (at P 375) to identify methods for Balancing Authorities to obtain Frequency Response. Requirement R1 allows Balancing Authorities to participate in Frequency Response Sharing Groups (FRSGs) to provide or obtain Frequency Response. These may be the same FRSGs that cooperate for BAL-002-0 or may be FRSGs that form for the purposes of BAL-003-1.

If BAs participate as an FRSG for BAL-003-1, compliance is based on the sum of the participants' performance.

Two other ways that BAs could obtain Frequency Response are through Supplemental Service or Overlap Regulation Service:

- No special action is needed if a BA provides or receives supplemental regulation. If the regulation occurs via Pseudo Tie, the transfer occurs automatically as part of Net Actual Interchange (NIA) and in response to information transferred from recipient to provider.
- If a BA provides overlap regulation, its FRS Form 1 will include the Frequency Bias setting as well as peak load and generation of the combined Balancing Authority Areas. The FRM event data will be calculated on the sum of the provider's and recipient's performance.

In the Violation Severity Levels for Requirement R1, the impact of a BA not having enough frequency response depends on two factors:

- Does the Interconnection have sufficient response?
- How short is the BA in providing its FRO?

The VSL takes these factors into account. While the VSLs look different than some other standards, an explanation would be helpful.

VSLs are a starting point for the enforcement process. The combination of the VSL and VRF is intended to measure a violation's impact on reliability and thus levy an appropriate sanction. Frequency Response is an interconnection-wide resource. The proposed VSLs are intended to put multi-BA Interconnections on the same plane as single-BA Interconnections.

Consider a small BA whose performance is 70% of its FRO. If all other BAs in the Interconnection are compliant, the small BA's performance has negligible impact on reliability, yet would be sanctioned at the same level as a BA who was responsible for its entire Interconnection. It is not rational to sanction this BA the same as a single BA Interconnection that had insufficient Frequency Response, because this would treat multi-BA Interconnections more harshly than single BA Interconnections on a significant scale.

The "Lower" and "Medium" VSLs say that the Interconnection has sufficient Frequency Response but individual BAs are deficient by small or larger amounts respectively. The High and Severe VSLs say the Interconnection does not meet the FRO and assesses sanctions based on whether the BA is deficient by a small or larger amount respectively.

Requirement 2

R2. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined in accordance with~~subject to~~ Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO.

Background and Rationale

Attachment A of the Standard discusses the process the ERO will follow to validate the BA's FRS Form 1 data and publish the official Frequency Bias Settings. Historically, it has taken multiple rounds of validation and outreach to confirm each BA's data due to transcription errors, misunderstanding of instructions, and other issues. While BAs historically submit Bias Setting data by January 1, it often takes one or more months to complete the process.

The target is to have BAs submit their data by January 10. The BAs are given 30 days to assemble their data since the BAs are dependent on the ERO to provide them with FRS Form 1, and there may be process delays in distributing the forms since they rely on identification of frequency events through November 30 of the preceding year.

Frequency Bias Settings generally change little from year to year. Given the fact that BAs can encounter staffing or EMS change issues coincident with the date the ERO sets for new Frequency Bias Setting implementation, the standard provides a 24 hour window on each side of the target date.

To recap the annual process:

1. The ERO posts the official list of frequency events to be used for this Standard in early December. The FRS Form 1 for each Interconnection will be posted shortly thereafter.

2. The Balancing Authority submits its revised annual Frequency Bias Setting value to NERC by January 10.

3. The ERO and the Resources Subcommittee validate Frequency Bias Setting values, perform error checking, and calculate, validate, and update CPS2 L10 values. This data collection and validation process can take as long as two months.

4. Once the L10 and Frequency Bias Setting values are validated, The ERO posts the values for the upcoming year and also informs the Balancing Authorities of the date on which to implement revised Frequency Bias Setting values. Implementation typically would be on or about March 1st of each year.

BAL-003-0.1b standard requires a minimum Frequency Bias Setting equal in absolute value to one percent of the Balancing Authority's estimated yearly peak demand (or maximum generation level if native load is not served). For most Balancing Authorities this calculated amount of Frequency Bias is significantly greater in absolute value than their actual Frequency Response characteristic (which represents an over-bias condition) resulting in over-control

since a larger magnitude response is realized. This is especially true in the Eastern Interconnection where this condition requires excessive secondary frequency control response which degrades overall system performance and increases operating cost as compared to requiring an appropriate balance of primary and secondary frequency control response.

Balancing Authorities were given a minimum Frequency Bias Setting obligation because there had never been a mandatory Frequency Response Obligation. This historic "one percent of peak per 0.1Hz" obligation, dating back to NERC's predecessor, NAPSIC, was intended to ensure all BAs provide some support to Interconnection frequency.

The ideal system control state exists when the Frequency Bias Setting of the Balancing Authority exactly matches the actual Frequency Response characteristic of the Balancing Authority. If this is not achievable, over-bias is significantly better from a control perspective than under-bias with the caveat that Frequency Bias is set relatively close in magnitude to the Balancing Authority actual Frequency Response characteristic. Setting the Frequency Bias to better approximate the Balancing Authority natural Frequency Response characteristic will improve the quality and accuracy of ACE control, CPS & DCS and general AGC System control response. This is the technical basis for recommending an adjustment to the long standing "1% of peak/0.1Hz" Frequency Bias Setting. The Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard is intended to bring the Balancing Authorities' Frequency Bias Setting closer to their natural Frequency Response. Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard balances the following objectives:

- Bring the Frequency Bias Setting and Frequency Response closer together.
- Allow time to analyze impact on other Standards (CPS, BAAL and to a lesser extent DCS) by adjustments in the minimum Frequency Bias Setting, by accommodating only minor adjustments.
- Do not allow the Frequency Bias Setting minimum to drop below natural Frequency Response, because under-biasing could affect an Interconnection adversely.

Additional flexibility has been added to the Frequency Bias Setting based on the actual Frequency Response (FRM) by allowing the Frequency Bias Setting to have a value in the range from 100% of FRM to 125% of FRM. This change has been included for the following reasons:

- When the new standardized measurement method is applied to BAs with a Frequency Response close to the interconnection minimum response, the requirement to use FRM is as likely to result in a Frequency Bias Setting below the actual response as it is to result in a response above the actual response. From a reliability perspective, it is

always better to have a Frequency Bias Setting slightly above the actual Frequency Response.

- As with single BA interconnections, the tuning of the control system may require that the BA implement a Frequency Response Setting slightly greater in absolute terms than its actual Frequency Response to get the best performance.

- The new standardized measurement method for determining FRM in some cases results in a measured Frequency Response significantly lower than the previous methods used by some BAs. It is desirable to not require significant change in the Frequency Bias Setting for these BAs that experience a reduction in their measured Frequency Response.

Requirement 3

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is:

- *Less than zero at all times, and*
- *Equal to or more negative than its Frequency Response Obligation when the Frequency varies from 60 Hz by more that +/- 0.036 Hz.*

Background and Rationale

In multi-Balancing Authority interconnections, the Frequency Bias Setting should be coordinated among all BAs on the interconnection. When there is a minimum Frequency Bias Setting requirement, it should apply for all BAs. However, BAs using a variable Frequency Bias Setting may have non-linearity in their actual response for a number of reasons including the dead-bands implemented on their generator governors. The measurement to ensure that these BAs are conforming to the interconnection minimum is adjusted to remove the dead-band range from the calculated average Frequency Bias Setting actually used. For BAs using variable bias, FRS Form 1 has a data entry location for the previous year's average monthly Bias. The Balancing Authority and the ERO can compare this value to the previous year's Frequency Bias Setting minimum to ensure R3 has been met.

On single BA interconnections, there is no need to coordinate the Frequency Bias Setting with other BAs. This eliminates the need to maintain a minimum Frequency Bias Setting for any reason other than meeting the reliability requirement as specified by the Frequency Response Obligation.

Requirement 4

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to either:

- *The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or*
- *The Frequency Bias Setting as shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities' Areas.*

Background and Rationale

This requirement reflects the operating principles first established by NERC Policy 1 and is similar to Requirement R6 of the approved BAL-003-0.1b standard. Overlap Regulation Service is a method of providing regulation service in which the Balancing Authority providing the regulation service incorporates another Balancing Authority's actual interchange, frequency response, and schedules into the providing Balancing Authority's AGC/ACE equation.

As noted earlier, a BA that is providing Overlap Regulation will report the sum of the Bias Settings in its FRS Form 1. Balancing Authorities receiving Overlap Regulation Service have an ACE and Frequency Bias Setting equal to zero (0).

How this Standard Meets the FERC Order 693 Directives

FERC Directive

The following is the relevant paragraph of Order No. 693.

> *Accordingly, the Commission approves Reliability Standard BAL-003-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to BAL-003-0 through the Reliability Standards development process that: (1) includes Levels of Non-Compliance; (2) determines the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other requirements of the Reliability Standard are being met, and to modify Measure M1 based on that determination and (3) defines the necessary amount of Frequency Response needed for Reliable Operation for each balancing authority with methods of obtaining and measuring that the frequency response is achieved.*

1. Levels of Non-Compliance

VRFs and VSLs are an equally effective way of assigning compliance elements to the standard.

2. Determine the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other Requirements of the Reliability Standard are met

BAL-003 V0 R2 (the basis of Order No. 693) deals with the calculation of Frequency Bias Setting such that it reflects natural Frequency Response.

The drafting team has determined that a sample size on the order of at least 20 events is necessary to have a high confidence in the estimate of a BA's Frequency Response. Selection of the frequency excursion events used for analysis will be done via a method outlined in Attachment A to the Standard.

On average, these events will represent the largest 2-3 "clean" frequency excursions occurring each month.

Since Frequency Bias Setting is an annual obligation, the survey of the at least 20 frequency excursion events will occur once each year.

3. Define the necessary amount of Frequency Response needed for Reliable Operation for each Balancing Authority with methods of obtaining and measuring that the frequency response is achieved

Necessary Amount of Frequency Response

The drafting team has proposed the following approach to defining the necessary amount of frequency response. In general, the goal is to avoid triggering the first step of under-frequency load shedding (UFLS) in the given Interconnection for reasonable contingencies expected. The

methodology for determining each Interconnection's and Balancing Authority's obligation is outlined in Attachment A to the Standard.

It should be noted the standard cannot guarantee there will never be a triggering of UFLS as the magnitude of "point C" differs throughout an interconnection during a disturbance and there are local areas that see much wider swings in frequency.

The contingency protection criterion is the largest reasonably expected contingency in the Interconnection. This can be based on the largest observed credible contingency in the previous 10 years or the largest Category C event for the Interconnection.

Attachment A to the standard presents the base obligation by Interconnection and adds a Reliability Margin. The Reliability Margin included addresses the difference between Points B and C and accounts for variables.

For multiple BA interconnections, the Frequency Response Obligation is allocated to BAs based on size. This allocation will be based on the following calculation:

$$\mathrm{FRO_{BA}} = \mathrm{FRO_{Int}} \times \frac{\text{Annual Gen}_{\mathrm{BA}} + \text{Annual Load}_{\mathrm{BA}}}{\text{Annual Gen}_{\mathrm{Int}} + \text{Annual Load}_{\mathrm{Int}}}$$

Methods of Obtaining Frequency Response

The drafting team believes the following are valid methods of obtaining Frequency Response:

- Regulation services.
- Contractual service. The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1. While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.

Measuring that the Frequency Response is Achieved

FRS Form 1 and the underlying data retained by the BA will be used for measuring whether Frequency Response was provided. FRS Form 1 will provide the guidance on how to account for and measure Frequency Response.

Going Beyond the Directive

Based on the combined operating experience of the SDT, the drafting team consensus is that each Interconnection has sufficient Frequency Response. If margins decline, there may be a need for additional standards or tools. The drafting team and the Resources Subcommittee are working with the ERO on its Frequency Response Initiative to develop processes and good practices so the Interconnections are prepared. These good practices and tools are described in the following section.

The drafting team is also evaluating a risk-based approach for basing the Interconnection Frequency Response Obligation on an historic probability density of frequency error, and for allocating the obligation on the basis of the Balancing Authority's average annual ACE share of frequency error. This allocation method uses the inverse of the rationale for allocating the CPS1 epsilon requirement by Bias share.

Good Practices and Tools

Background

This section outlines tips and tools to help Balancing authorities meet the Frequency Response Standard or to operate more reliably. If you have suggested additions, please send them to balancing@nerc.com.

Identifying and Estimating Frequency Responsive Reserves

Knowing the quantity and depth of frequency responsive reserves in real time is a possible next step to being better prepared for the next event. The challenge in achieving this is having the knowledge of the capabilities of all sources of frequency response. Presently the primary source of Frequency Response remains with the generation resources in our fleets.

Understanding how each of these sources performs to changes in system frequency and knowing their limitations would improve the BA's ability to measure frequency responsive reserves. Presently there are only guidelines, criteria and protocols in some regions of the industry that identify specific settings and performance expectations of Primary Frequency Response of resources.

One method of gaining a better understanding of performance is to measure performance during actual events that occur on the system. Measuring performance during actual events would only provide feedback for performance during that specific event and would not provide insight into depth of response or other limitations.

Repeated measurements will increase confidence in expected performance. NERC modeling standards are in process to be revised that will improve the BA's insight into predicting available frequency responsive reserves. However, knowing how resources are operated, what modes of operation provide sustained Primary Frequency Response and knowing the operating range of this response would give the BA the knowledge to accurately predict frequency response and the amount of frequency responsive reserves available in real time.

Some benefits have been realized by communicating to generation resources (GO) the importance of operating in modes that allow Primary Frequency Response to be sustained by the control systems of the resource. Other improvements in implementation of Primary Frequency Response have been achieved through improved settings on turbine governors through the elimination of "step" frequency response with the simultaneous reduction in governor dead-band settings.

Improvements in the full AGC control loop of the generating resource, which accounts for the expected Primary Frequency Response, have improved the delivery of quality Primary Frequency Response while minimizing secondary control actions of generators. Some of these actions can provide quick improvement in delivery of Primary Frequency Response.

Once Primary Frequency Response sources are known, the BA could calculate available reserves that are frequency responsive. Planning for these reserves during normal and emergency operations could be developed and added to the normal planning process.

Using FRS Form 1 Data

The information collected for this standard can be supplemented by a few data points to provide the Balancing Authority useful tools and information. The BA could do a regression analysis of its frequency response against the following values:

- Load (value A).
- Interchange (Value A).
- Total generation.
- Spinning reserve.

While the last two values above are not part of Form 1, they should be readily available. Small BAs might even include headroom on its larger generators as part of the regression.

The regression would provide a formula the BA could program in its EMS to present the operator a real time estimate of the BA's Frequency Response.

Statistical outliers in the regression would point to cases meriting further inspection to find causes of low Frequency Response or opportunities for improvement.

Tools

Single generating resource performance evaluation tools for steam turbine, combustion turbine (simple cycle or combined cycle) and for intermittent resources are available at the following link. http://texasre.org/standards_rules/standardsdev/rsc/sar003/Pages/Default.aspx.

These tools and the regional standard associated with them are in their final stages of development in the Texas region.

These tools will be posted on the NERC website.

Appendix 1 - Data Quality Concerns Related To The Use Of The Actual Net Interchange Value

Actual net interchange for a typical Balancing Authority (BA) is the summation of its tie lines to other BAs. In some cases, there are pseudo-ties in it which reflect the effective removal or addition of load and/or generation from another BA, or it could include supplemental regulation as well. But in the typical scenario, actual net interchange values that are extracted from EMS data archiving can be influenced by data latency times in the data acquisition process, and also any timestamp skewing in the archival process.

Of greater concern, however, are the inevitable variations of other operating phenomena occurring concurrently with a frequency event. The impacts of these phenomena are superimposed on actual net interchange values along with the frequency response that we wish to measure through the use of the actual net interchange value.

To explore this issue further, let's begin with the idealized condition:

- frequency is fairly stable at some value near or a little below 60 Hz
- ACE of the non-contingent BA of interest is 0 and has been 0 for an extended period, and AGC control signals have not been issued recently
- Actual net interchange is "on schedule", and there are no schedule changes in the immediate future
- BA load is flat
- All generators not providing AGC are at their targets
- Variable generation such as wind and solar are not varying
- Operators have not directed any manual movements of generation recently

And when the contingency occurs in this idealized state, the change in actual net interchange will be measuring only the decline in load due to lesser frequency and generator governor response, and, none of the contaminating influences. While the ACE may become negative due to the actual frequency response being less than that called for by the frequency bias setting within the BA's AGC system, this contaminating influence on measuring frequency response will not appear in the actual net interchange value if the measurement interval ends before the generation on AGC responds.

Now let's explore the sensitivity of the resultant frequency response sampling to the relaxation of these idealized circumstances.

1. The "60 Hz load" increases moderately due to time of day concurrent with the frequency event. If the frequency event happens before AGC or operator-directed manual load adjustments occur, then the actual net interchange will be reduced by the moderate increase in load and the frequency response will be underestimated. But if the frequency event happens while AGC response and/or manual adjustments occur, then the actual net interchange will be increased by the AGC response (and/or manual adjustments) and the frequency response will be overestimated.

2. The “60 Hz load” decreases moderately due to time of day concurrent with the frequency event. If the frequency event happens before AGC or operator-directed manual load adjustments occur, then the actual net interchange will be increased by the moderate reduction in load and the frequency response will be overestimated. But if the frequency event happens while AGC response and/or manual adjustments occur, then the actual net interchange will be decreased by the AGC response (and/or manual adjustments) and the frequency response will be underestimated.
3. In anticipation of increasing load during the next hour, the operator increases manual generation before the load actually appears. If the frequency event happens while the generation “leading” the load is increasing, then the actual net interchange will be increased by the increase in manual generation and the frequency response will be overestimated. But if the frequency event occurs when the result of AGC signals sent to offset the operator’s leading actions take effect, then the actual net interchange will be decreased and the frequency response is underestimated.
4. In anticipation of decreasing load during the next hour, the operator decreases manual generation before the load actually declines. If the frequency event happens while the generation “leading” the load downward is decreasing, then the actual net interchange will be decreased by the reduction in manual generation and the frequency response will be underestimated. But if the frequency event occurs when the result of AGC signals sent to offset the operator’s leading actions take effect, then the actual net interchange will be increased and the frequency response is overestimated.
5. A schedule change to export more energy is made at 5 minutes before the top of the hour. The BA’s “60 Hz load” is not changing. The schedule change is small enough that the operator is relying on upward movement of generators on AGC to provide the additional energy to be exported. The time at which the AGC generators actually begin to provide the additional energy is dependent on how much time passes before the AGC algorithm gets out of its deadbands, the individual generator control errors get large enough for sending out the control signal, and maybe 20 seconds to 3 minutes for the response to be effected. The key point here is that it is not clear when the effects of a schedule change, as manifested in a change in generation and then ultimately a change in actual net interchange, will occur.
6. With the expected penetration of wind in the near future, unanticipated changes in their output will tend to affect actual net interchange and add noise to the frequency response observation process.

To a greater or lesser extent, 1 through 4 above are happening continuously for the most part with most BAs in the Eastern and Western Interconnections. The frequency response is buried within the typical hour to hour operational cacophony superimposed on actual net interchange values. The choice of metrics will be important to artfully extract frequency response from the noise and other unrepresentative error.

Project 2007-12 Frequency Response BAL-003-1
Mapping Document

Standard: BAL-003-1 Frequency Response and Frequency Bias Setting		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
R1. Each Balancing Authority shall review its Frequency Bias Settings by January 1 of each year and recalculate its setting to reflect any change in the Frequency Response of the Balancing Authority Area. R1.1. The Balancing Authority may change its Frequency Bias Setting, and the method used to determine the setting, whenever any of the factors used to determine the current bias value change. R1.2. Each Balancing Authority shall report its Frequency Bias Setting, and method	This Requirement has been moved into BAL-003-1 Attachment A & FRS Form 1 as described in the Proposed Language Section	Attachment A Balancing Authorities that merge or that transfer load or generation are encouraged to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation to the Interconnection remains the same and so that CPS limits can be adjusted. Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO each year to allow the ERO to validate the revised Frequency Bias Settings on FRS Form 1. If the ERO posts the official list of events after the date specified in the timeline below, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to

Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
for determining that setting, to the NERC Operating Committee.		submit their FRS Form 1. AND FRS Form 1 Note : Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1.
R2. Each Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response. Frequency Bias may be calculated several ways: **R2.1.** The Balancing Authority may use a fixed Frequency Bias value which is based on a fixed, straight-line function of Tie Line deviation versus Frequency Deviation. The	This Requirement is included in BAL-003-1 as described in the Proposed Language Section.	**R2.** Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined subject to Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO. **R3.** Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and is utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias setting that is:

Standard: BAL-003-1 Frequency Response and Frequency Bias Setting		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
Balancing Authority shall determine the fixed value by observing and averaging the Frequency Response for several Disturbances during on-peak hours. **R2.2.** The Balancing Authority may use a variable (linear or non-linear) bias value, which is based on a variable function of Tie Line deviation to Frequency Deviation. The Balancing Authority shall determine the variable frequency bias value by analyzing Frequency Response as it varies with factors such as load, generation, governor characteristics, and frequency.		3.1 Less than zero at all times, and 3.2 Equal to or more negative than its Frequency Response Obligation when Frequency varies from 60 Hz by more than +/- 0.036 Hz. AND Attachment A Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO each year to allow the ERO to validate the revised Frequency Bias Settings on FRS Form 1. If the ERO posts the official list of events after the date specified in the timeline below, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to submit their FRS Form 1. AND FRS Form 1

Standard: BAL-003-1 Frequency Response and Frequency Bias Setting		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
		Note : Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1. AND A portion of this Requirement is being phased out in accordance with the process detailed in the Procedure. This phase out is intended to bring the Frequency Bias Setting closer or equal to the natural Frequency Response.
R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability.	This Requirement has been removed from the BAL-003-1 standard.	This Requirement has been removed from proposed standard BAL-003-I. It is duplicative of BAL-005-0.1b Requirements R6 and R7. BAL-005-0.1b R6. The Balancing Authority's AGC shall compare total Net Actual Interchange to total Net Scheduled Interchange plus Frequency Bias obligation to determine the Balancing Authority's ACE. Single Balancing Authorities operating asynchronously may employ alternative ACE calculations such as (but not limited to) flat frequency control. If a Balancing Authority is unable to calculate ACE for more than 30 minutes it shall notify its

Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
		Reliability Coordinator. R7. The Balancing Authority shall operate AGC continuously unless such operation adversely impacts the reliability of the Interconnection. If AGC has become inoperative, the Balancing Authority shall use manual control to adjust generation to maintain the Net Scheduled Interchange.
R4. Balancing Authorities that use Dynamic Scheduling or Pseudo-ties for jointly owned units shall reflect their respective share of the unit governor droop response in their respective Frequency Bias Setting. R4.1. Fixed schedules for Jointly Owned Units mandate that Balancing Authority (A) that contains the Jointly Owned Unit must incorporate the respective share of the unit governor droop response for any Balancing Authorities that have fixed	This Requirement has been removed from the BAL-003-1 standard.	This Requirement addresses how to calculate Frequency Bias Settings. This is no longer needed since the Frequency Bias Settings are calculated in FRS Form 1 using Frequency Response associated with the "official" list of events and a couple of "floor or ceiling" limits (% of peak load/gen and FRO). The entire calculation is built into the FRS Form 1 workbook.

Standard: BAL-003-1 Frequency Response and Frequency Bias Setting		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
schedules (B and C). R4.2. The Balancing Authorities that have a fixed schedule (B and C) but do not contain the Jointly Owned Unit shall not include their share of the governor droop response in their Frequency Bias Setting.		
R5. Balancing Authorities that serve native load shall have a monthly average Frequency Bias Setting that is at least 1% of the Balancing Authority's estimated yearly peak demand per 0.1 Hz change. **R5.1.** Balancing Authorities that do not serve native load shall have a monthly average Frequency Bias Setting that is at least 1% of its estimated maximum generation level in the coming year per 0.1 Hz change.	This Requirement has been combined into Requirements R2 and R3 of BAL-003-1.	**R2.** Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined subject to Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO. **R3.** Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and is utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias setting that is: 3.1 Less than zero at all times, and 3.2 Equal to or more negative than its Frequency

Standard: BAL-003-1 Frequency Response and Frequency Bias Setting		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in BAL-003-1/Comments**
		Response Obligation when Frequency varies from 60 Hz by more than +/- 0.036 Hz.
R6. A Balancing Authority that is performing Overlap Regulation Service shall increase its Frequency Bias Setting to match the frequency response of the entire area being controlled. A Balancing Authority shall not change its Frequency Bias Setting when performing Supplemental Regulation Service.	This Requirement has been moved into BAL-003-1 Requirement R4.	**R4.** Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to either: • The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or • The Frequency Bias Setting as shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities' Areas.

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-12 – Frequency Response

This document provides the drafting team's justification for assigning draft standard Requirement violation risk factors (VRFs) and violation severity levels (VSLs) for:

- BAL-003-1 — Frequency Response and Frequency Bias Setting

Each primary Requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violation of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Frequency Response Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the

ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs[1]:

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report
The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard
The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards
The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

[1] North American Electric Reliability Corp., 119 FERC 61,145, order on reh'g and compliance filing, 120 FERC 61,145 (2007) ("VRF Rehearing Order").
[2] Id. at footnote 15.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in this standard meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties per violation per day basis is the “default” for penalty calculations.

VRF and VSL Justification

BAL-003-1 VRF and VSL Justifications		
R1	Proposed VRF	Medium
	NERC VRF Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support for the contingency. This is consistent with the NERC definition.
	FERC VRF G1 Discussion	This Requirement is more administrative in nature requiring calculated FRM to be equal to or more negative than FRO. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement.
	FERC VRF G2 Discussion	Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting.
	FERC VRF G3 Discussion	The Requirement VRF is consistent with other BES standards addressing responsiveness. This requirement is similar in concept to the current enforceable BAL-003-0.1b standard Requirement R2 which specifies a Medium VRF.
	FERC VRF G4 Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support for the contingency. This is consistent with the NERC definition.
	FERC VRF G5	This requirement does not co-mingle reliability objectives.

	Discussion	
	Proposed Lower VSL	The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 1% but by at most 30% or 15 MW/0.1 Hz, whichever one is the greater deviation from its FRO
	Proposed Moderate VSL	The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 30% or by more than 15 MW/0.1 Hz, whichever is the greater deviation from its FRO
	Proposed High VSL	The summation of the Balancing Authorities' FRM within an Interconnection did not meet its FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 1% but by at most 30% or 15 MW/0.1 Hz, whichever one is the greater deviation from its FRO
	Proposed Severe VSL	The summation of the Balancing Authorities' FRM within an Interconnection did not meet its FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than 30% or by more than 15 MW/0.1 Hz, whichever is the greater deviation from its FRO
	Compliance with NERC Revised VSL Guidelines	The NERC VSL guidelines are satisfied by incorporating percentage of noncompliance performance for the calculated FRM being less negative than FRO.
	FERC VSL G1 Discussion	This is not applicable since there was not a Requirement mandating a certain level of Frequency Response prior to this standard.
	FERC VSL G2 Discussion	Proposed VSL's is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on the amount the calculated FRM is less negative than FRO.
	FERC VSL G3 Discussion	Proposed VSL's do not expand on what is required. The VSL's assigned only consider results of the calculation required. Proposed VSL's are consistent with the requirement.
	FERC VSL G4 Discussion	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

R2	Proposed VRF	Medium
	NERC VRF Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support f the contingency. This is consistent with the NERC definition.
	FERC VRF G1 Discussion	This Requirement is more administrative in nature requiring entities to implement the Frequency Bias Setting validated by the ERO. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement.
	FERC VRF G2 Discussion	Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting.
	FERC VRF G3 Discussion	The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF however BAL-003-1 Requirements R1, R3, and R4 specify a Medium VRF and the SDT believes it is appropriate for this Requirement to also possess a Medium VRF given the nature of the revision to BAL-003-0.1b.
	FERC VRF G4 Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support f the contingency. This is consistent with the NERC definition.
	FERC VRF G5 Discussion	This requirement does not co-mingle reliability objectives.

	Proposed Lower VSL	The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting failed to implement the validated Frequency Bias Setting value into its ACE calculation within the implementation period specified but did so within 5 calendar days from the implementation period specified by the ERO.
	Proposed Moderate VSL	The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting implemented the validated Frequency Bias Setting value into its ACE calculation in more than 5 calendar days but less than or equal to 15 calendar days from the implementation period specified by the ERO.
	Proposed High VSL	The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting implemented the validated Frequency Bias Setting value into its ACE calculation in more than 15 calendar days but less than or equal to 25 calendar days from the implementation period specified by the ERO.
	Proposed Severe VSL	The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting did not implement the validated Frequency Bias Setting value into its ACE calculation in more than 25 calendar days from the implementation period specified by the ERO.
	Compliance with NERC Revised VSL Guidelines	The NERC VSL guidelines are satisfied by incorporating increments for tardiness implementing the validated Frequency Bias Setting into the ACE calculation.
	FERC VSL G1 Discussion	This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF. Proposed VSL's meet or exceed the current threshold of compliance.
	FERC VSL G2 Discussion	Proposed VSL's is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on how late the validated Frequency Bias Setting is implemented.
	FERC VSL G3 Discussion	Proposed VSL's do not expand on what is required. The VSL's assigned only consider performance of required action. Proposed VSL's are consistent with the requirement.
	FERC VSL G4	Proposed VSL's are based on a single violation and not a cumulative

	Discussion	violation methodology.

R3	Proposed VRF	Medium
	NERC VRF Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting in its ACE equation and would provide support for a contingency. This is consistent with the NERC definition.
	FERC VRF G1 Discussion	This Requirement is more administrative in nature requiring entities to implement a Frequency Bias Setting validated by the ERO. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement.
	FERC VRF G2 Discussion	Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting.
	FERC VRF G3 Discussion	The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF however BAL-003-1 Requirements R1, R2, and R4 specify a Medium VRF and the SDT believes it is appropriate for this Requirement to also possess a Medium VRF given the nature of the revision to BAL-003-0.1b.
	FERC VRF G4 Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support for a contingency. This is consistent with the NERC definition.
	FERC VRF G5	This requirement does not co-mingle reliability objectives.

	Discussion	
	Proposed Lower VSL	The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clock-minute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response Obligation by more than 1% but by at most 10%.
	Proposed Moderate VSL	The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clock-minute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response Obligation by more than 10% but by at most 20%.
	Proposed High VSL	The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clock-minute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response Obligation by more than 20% but by at most 30%.
	Proposed Severe VSL	The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clock-minute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response obligation by more than 30%..
	Compliance with NERC Revised VSL Guidelines	The NERC VSL guidelines are satisfied by incorporating percentage of noncompliance performance for the calculated average Frequency Bias Setting being less negative than its minimum as defined in Attachment B.
	FERC VSL G1 Discussion	This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Medium VRF. Proposed VSL's meet or exceed the current threshold of compliance.
	FERC VSL G2 Discussion	Proposed VSL is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based on the calculated average Frequency Bias Setting being less negative than its minimum as defined in Attachment B.

	FERC VSL G3 Discussion	Proposed VSL does not expand on what is required. The VSLs assigned only consider compliance with the Frequency Bias Setting calculation and implementation required. Proposed VSL's are consistent with the requirement.
	FERC VSL G4 Discussion	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

R4	Proposed VRF	Medium
	NERC VRF Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support f the contingency. This is consistent with the NERC definition. In addition, this Requirement VRF is consistent with the BAL-003-0 Requirement which has been approved by FERC.
	FERC VRF G1 Discussion	This Requirement is more administrative in nature requiring entities providing Overlap Regulation Services to correctly increase its Frequency Bias Setting. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement.
	FERC VRF G2 Discussion	Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting.
	FERC VRF G3 Discussion	The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R6 which specifies a Medium VRF
	FERC VRF G4 Discussion	This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the

		previous year's Frequency Bias Setting already in its ACE equation and would provide support f the contingency. This is consistent with the NERC definition. In addition, this Requirement VRF is consistent with the BAL-003-0 Requirement which has been approved by FERC.
	FERC VRF G5 Discussion	This requirement does not co-mingle reliability objectives.
	Proposed Lower VSL	The Balancing Authority incorrectly changed the Frequency Bias Setting value used in its ACE calculation when providing Overlap Regulation Services with combined footprint setting error less than 10% of the validated or calculated value.
	Proposed Moderate VSL	The Balancing Authority incorrectly changed the Frequency Bias Setting value used in its ACE calculation when providing Overlap Regulation Services with combined footprint setting error more than 10% but less than or equal to 20% of the validated or calculated value
	Proposed High VSL	The Balancing Authority incorrectly changed the Frequency Bias Setting value used in its ACE calculation when providing Overlap Regulation Services with combined footprint setting error more than 20% but less than or equal to 30% of the validated or calculated value.
	Proposed Severe VSL	The Balancing Authority incorrectly changed the Frequency Bias Setting value used in its ACE calculation when providing Overlap Regulation Services with setting error more than 30% of the validated or calculated value. OR The Balancing Authority failed to change the Frequency Bias Setting value used in its ACE calculation when providing Overlap Regulation Services
	Compliance with NERC Revised VSL Guidelines	The NERC VSL guidelines are satisfied by incorporating percentage of noncompliance performance for the absolute value of the Balancing Authorities' calculated monthly average Frequency Bias Setting being below the minimum percentage specified by the ERO. The VSL also includes a binary requirement for failing to change the Frequency Bias Setting value when providing Overlap Regulation Services.
	FERC VSL G1 Discussion	This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R6 which specifies a Medium VRF. Proposed VSL's meet or exceed the current threshold of compliance.
	FERC VSL G2 Discussion	Proposed VSL's has both a percentage of noncompliance performance and binary element. The binary element is designated severe. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on the amount the calculated monthly average Frequency Bias Setting is below the minimum percentage specified

		by the ERO or if the entity fails to change the Frequency Bias Setting value when providing Overlap Regulation Services.
	FERC VSL G3 Discussion	Proposed VSL's do not expand on what is required. The VSL's assigned only consider results of the calculation required and if the Frequency Bias Setting is correctly set when providing Overlap Regulation Services. Proposed VSL's are consistent with the requirement.
	FERC VSL G4 Discussion	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Frequency Response Initiative Report

The Reliability Role of Frequency Response

October 30, 2012

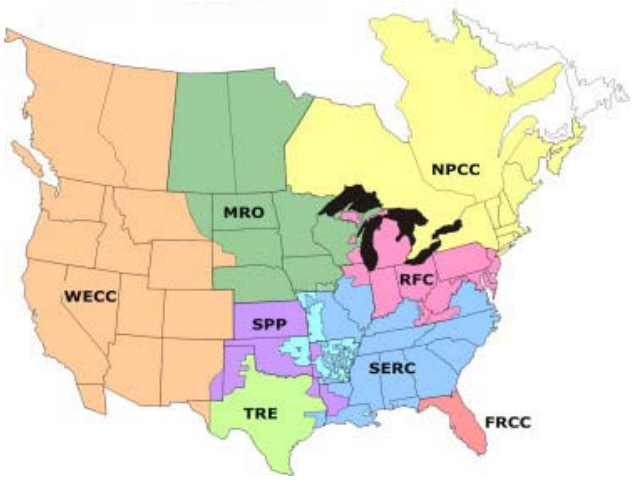
RELIABILITY | ACCOUNTABILITY

3353 Peachtree Road NE
Suite 600, North Tower
Atlanta, GA 30326
404-446-2560 | www.nerc.com

NERC's Mission

The North American Electric Reliability Corporation's (NERC) mission is to ensure the reliability of the North American bulk power system. NERC is the electric reliability organization (ERO) certified by the Federal Energy Regulatory Commission (FERC) to establish and enforce reliability standards for the bulk power system. NERC develops and enforces reliability standards; assesses adequacy annually via a 10-year forecast and summer and winter forecasts; monitors the bulk power system; and educates, trains, and certifies industry personnel. ERO activities in Canada related to the reliability of the bulk power system are recognized and overseen by the appropriate governmental authorities in that country.[1]

NERC assesses and reports on the reliability and adequacy of the North American bulk power system, which is divided into eight Regional areas, as shown on the map and table below. The users, owners, and operators of the bulk power system within these areas account for virtually all the electricity supplied in the United States, Canada, and a portion of Baja California Norte, Mexico.



Note: The highlighted area between SPP RE and SERC denotes overlapping Regional area boundaries. For example, some load-serving entities participate in one Region and their associated transmission owner/operators in another.

NERC Regional Entities	
FRCC Florida Reliability Coordinating Council	**SERC** SERC Reliability Corporation
MRO Midwest Reliability Organization	**SPP RE** Southwest Power Pool Regional Entity
NPCC Northeast Power Coordinating Council	**TRE** Texas Reliability Entity
RFC ReliabilityFirst Corporation	**WECC** Western Electricity Coordinating Council

[1] As of June 18, 2007, FERC granted NERC the legal authority to enforce reliability standards with all U.S. users, owners, and operators of the bulk power system, and made compliance with those standards mandatory and enforceable. In Canada, NERC has memorandums of understanding in place with provincial authorities in Ontario, New Brunswick, Nova Scotia, Québec, and Saskatchewan, and with the Canadian National Energy Board. NERC standards are mandatory and enforceable in Ontario and New Brunswick as a matter of provincial law. NERC has an agreement with Manitoba Hydro that makes reliability standards mandatory for that entity, and Manitoba has recently adopted legislation setting out a framework for standards to become mandatory for users, owners, and operators in the province. In addition, NERC has been designated the "electric reliability organization" under Alberta's Transportation Regulation, and certain reliability standards have been approved in that jurisdiction; others are pending. NERC and NPCC have been recognized as standards-setting bodies by the Régie de l'énergie of Québec, and Québec has the framework in place for reliability standards to become mandatory. Nova Scotia and British Columbia also have frameworks in place for reliability standards to become mandatory and enforceable. NERC is working with the other governmental authorities in Canada to achieve equivalent recognition.

This report was approved by the Planning Committee October 4, 2012, via e-mail vote.

This report was accepted by the Operating Committee October 12, 2012, via e-mail vote.

Introduction

System planning and operations experts are anticipating significantly higher penetrations of renewable energy resources, most of which are electronically coupled to the grid. This presents some new and different technical challenges, particularly in the reduction of system inertia through the displacement of conventional generation resources during light load periods. Load management and other demand-side initiatives also continue to grow. Most importantly, a continued downward trend for frequency response over a number of years has raised concern that credible contingencies may result in frequency excursions that encroach on the first step of under-frequency load shedding (UFLS). Such large frequency excursions could also trigger undesirable reactions from frequency-sensitive smart grid loads and electronically coupled renewable resources. Taken together, it is clear that maintaining adequate frequency response for bulk power system reliability is becoming more important and complex. While the decline in frequency response has lessened in the last couple of years, it is important that the industry understands the growing complexities of frequency control and is ready with comprehensive strategies to stay ahead of any potential problems.

NERC has undertaken various activities over the past few years in an effort to understand the steady decline in frequency response, particularly in the Eastern Interconnection. While some significant insight has been gained and system-wide and technical improvements have been achieved in the Western Interconnection and ERCOT, a deeper and more dedicated effort is needed.

To comprehensively address the issues related to frequency response, NERC launched the Frequency Response Initiative in 2010. In addition to coordinating the myriad of efforts underway in standards development and performance analysis, the initiative includes performing in-depth analysis of interconnection-wide frequency response to achieve a better understanding of the factors influencing frequency performance across North America.

Basic objectives of the Frequency Response Initiative include:

- development of a clearer and more specific statement of frequency-related reliability factors, including better definitions for “ownership” of responsibility for frequency response;
- collection and provision of more granular frequency response data on and technical analyses of frequency-driven bulk power system events, including root cause analyses;
- metrics and benchmarks to improve frequency response performance tracking;
- increasing coordinated communication and outreach on the issue to include webinars and NERC alerts and to share lessons learned; and
- focused discussion on communication of emerging technology issues, including frequency-related effects caused by renewable energy integration, smart grid technology deployment, and new end-use technology.

In March 2011, the NERC Planning Committee tasked the Transmission Issues Subcommittee (TIS, now the System Analysis and Modeling Subcommittee (SAMS)) with determining what criteria should be used to decide the appropriate level of interconnection-wide frequency response needed for reliability. The TIS started with a body of work already underway by the Resources Subcommittee (RS) and the Frequency Working Group (FWG) of the Operating Committee, and the Frequency Responsive Reserve Standard Drafting Team (FRRSDT). The RS produced a position paper on frequency response outlining the method to translate a resource contingency criterion into an Interconnection Frequency Response Obligation (IFRO).

The report on IFRO was approved by the Planning Committee September 2011.[2] Since that time, numerous modifications and improvements have been made to the IFRO determination analysis and calculations. Those changes are reflected in the IFRO section of this report.

This report provides an overview of the work that has been done to date toward gaining understanding of frequency response. It is in support of NERC Standards Project 2007-12 Frequency Response, which is preparing a revised draft standard (BAL-003-1). That standard is intended to codify a Frequency Response Obligation and means for measuring the performance of the Balancing Authorities.

Executive Summary

Recommendations

1. NERC should embark immediately on the development of a NERC Frequency Response Resource Guideline to define the performance characteristics expected of those resources for supporting reliability. That guideline should address appropriate parameters for the following:

   - Existing conventional generator fleet – In order to retain or regain frequency response capabilities of the existing generator fleet, adopt:
     - deadbands of ±16.67 mHz,
     - droop settings of 3%–5% depending on turbine type,
     - continuous, proportional (non-step) implementation of the response,
     - appropriate operating modes to provide frequency response, and
     - appropriate outer-loop controls modifications to avoid primary frequency response withdrawal at a plant level.

   - Other frequency-responsive resources – Augment existing generation response with fast-acting, electronically coupled frequency responsive resources, particularly for the arresting and rebound periods of a frequency event:
     - contractual high-speed demand-side response,
     - wind and photo-voltaic – particularly for over-frequency response,
     - storage – automatic high-speed energy retrieval and injection, and
     - variable-speed drives – non-critical, short-time load reduction.

2. Instead of using a fixed margin, the calculation of the Interconnection Frequency Response Obligations should use statistical analysis to determine the necessary margin.

3. The starting frequency for the calculation of IFROs should be the frequency 5% of the lower tail of samples from the statistical analysis, representing a 95% confidence that frequencies will be at or above that value at the start of any frequency event, as shown in table A.

Table A: Interconnection Frequency Variation Analysis (Hz)

Value	Eastern	Western	ERCOT	Québec
Starting Frequency (F_{Start})	59.974	59.976	59.963	59.972

4. The recommended UFLS first-step limitations for IFRO calculations are listed in table B.

Table B: Low-frequency Limits (Hz)	
Interconnection	Highest UFLS Trip Frequency
Eastern	59.5[3]
Western	59.5
ERCOT	59.3
Québec	58.5

5. The allowable frequency deviation (starting frequency minus the highest UFLS step) should be reduced to account for differences between the 1-second and sub-second data for Point C (frequency nadir) by a statistically determined adjustment as listed in table C. Sub-second measurements will more accurately detect Point C.

Table C: Analysis of 1-Second and Sub-Second Data for Point C (CC_{ADJ})				
Interconnection	Number of Samples	Mean	Standard Deviation	CC_{ADJ} (95% Quantile)
Eastern	30	0.0006	0.0038	0.0068
Western	17	0.0012	0.0019	0.0044
ERCOT	58	0.0021	0.0061	0.0121
Québec	0	N/A	N/A	N/A

6. The allowable change in frequency from the IFRO Starting Frequency should be adjusted by a statistically determined value to account for the differences between the Value B and the Point C for historical frequency events as listed in table D.

Table D: Analysis of B Value and Point C (CB_R)				
Interconnection	Number of Samples	Mean	Standard Deviation	CB_R (95% Quantile)
Eastern	41	0.964	0.0149	1.0 (0.989)[4]
Western	30	1.570	0.0326	1.625
ERCOT	88	1.322	0.0333	1.377
Québec[5]	N/A	1		1.550

[3] The highest UFLS setpoint in the Eastern Interconnection is 59.7 Hz in FRCC, based on internal stability concerns. The FRCC concluded that the IFRO starting frequency of the prevalent 59.5 Hz for the Eastern Interconnection is acceptable in that it imposes no greater risk of UFLS operation in FRCC for an external resource loss event than for an internal FRCC event.

[4] CB_R value limited to 1.0 because values lower than that indicate the Value B is lower than Point C and does not need to be adjusted. The calculated value is 0.989.

7. An adjustment should be made to the maximum allowable delta frequency to compensate for the predominant withdrawal of primary frequency response exhibited in an interconnection until such withdrawal is no longer exhibited in that interconnection.

8. The determination of the maximum delta frequencies should be calculated in accordance with the methods embodied in Table E – Determination of Maximum Delta Frequencies.

Table E: Determination of Maximum Delta Frequencies

	Eastern	Western	ERCOT	Québec	Units
Starting Frequency	59.974	59.976	59.963	59.972	Hz
Minimum Frequency Limit	59.500	59.500	59.300	58.500	Hz
Base Delta Frequency	0.474	0.476	0.663	1.472	Hz
CC_{ADJ} [6]	0.007	0.004	0.012	N/A	Hz
Delta Frequency (DF_{CC})	0.467	0.472	0.651	1.472	Hz
CB_R [7]	1.000[8]	1.625	1.377	1.550[9]	Hz
Delta Frequency (DF_{CBR})[10]	0.467	0.291	0.473	0.949	Hz
BC'_{ADJ} [11]	.018	N/A	N/A	N/A	Hz
Max. Delta Frequency	0.449	0.291	0.473	0.949	Hz

[5] Based on Québec UFLS design between their 58.5 Hz UFLS with 300 millisecond operating time (responsive to Point C) and 59.0 Hz UFLS step with a 20-second delay (responsive to Value B or beyond) with a 0.05 Hz confidence interval. See the Adjustment for Differences between Value B and Point C section of this report for further details.

[6] Adjustment for the differences between 1-second and sub-second Point C observations for frequency events.

[7] Adjustment for the differences between Point C and Value B.

[8] CB_R value for the Eastern Interconnection limited to 1.0 because values lower than that indicate the Value B is lower than Point C and does not need to be adjusted. The calculated value is 0.989.

[9] Based on Québec UFLS design between their 58.5 Hz UFLS with 300 ms operating time (responsive to Point C)and 59.0 Hz UFLS step with a 20-second delay (responsive to Value B or beyond).

[10] DF_{CC}/CB_R

[11] Adjustment for the event nadir being below the Value B (Eastern Interconnection only) due to primary frequency response withdrawal.

9. The Interconnection Frequency Response Obligations should be calculated as shown in Table F: Recommended IFROs.

Table F: Recommended IFROs					
	Eastern	Western	ERCOT	Québec	Units
Starting Frequency	59.974	59.976	59.963	59.972	Hz
Max. Delta Frequency	0.449	0.291	0.473	0.949	Hz
Resource Contingency Protection Criteria	4,500	2,740	2,750	1,700	MW
Credit for LR	–	300	1,400	–	MW
IFRO[12]	-1,002	-840	-286	-179	MW/0.1Hz
Absolute Value of IFRO	1,002	840	286	179	MW/0.1Hz
% of Current Interconnection Performance[13]	40.6%	71.2%	48.7%	23.9%	
% of Interconnection Load[14]	0.17%	0.56%	0.45%	0.50%	

10. NERC and the Western Interconnection should analyze the FRO allocation implications of the Pacific Northwest RAS generation tripping of 3,200 MW.

11. Trends in frequency response sustainability should be measured and tracked by observing frequency between T+45 seconds and T+180 seconds. A pair of indices for gauging sustainability should be calculated comparing that value to both the Point C and Value B.

12. Frequency response performance by Balancing Authorities should not be judged for compliance on a per-event basis.

13. Linear regression is the method that should be used for calculating Balancing Authority Frequency Response Measure (FRM) for compliance with Standard BAL-003-1 – Frequency Response.

[12] IFRO =

[13] Current Interconnection Frequency Response Performance: EI = -2,467 MW / 0.1Hz, WI = -1,179 MW / 0.1Hz, TI = -586 MW / 0.1Hz, and QI = -750 MW/0.1 Hz.

[14] Interconnection projected Total Internal Demands from the 2010 NERC Long-Term Reliability Assessment: EI = 604,245 MW, WI = 148,895 MW, TI = 63,810 MW, and QI winter load = 36,000 MW.

14. NERC and the Frequency Working Group should annually review the process for detection of frequency events and the method for calculating the A and B Values and Point C. The associated interconnection frequency event database, methods for calculating interconnection metrics on risks to reliability, the associated probabilities, and the calculation of the IFROs using updated data should also undergo review in an effort to improve the process. Throughout this process, NERC should strive to improve the quality and consistency of the data measurements.

15. NERC should address improving the level of understanding of the role of turbine governors through seminars and webinars, with educational materials available to the Generator Owners and Generator Operators on an ongoing basis.

16. When the Eastern Interconnection Reliability Assessment Group Multiregional Modeling Working Group (ERAG MMWG) completes its review of turbine governor modeling, a new light-load case should be developed, and the resource loss criterion for the Eastern Interconnection's IFRO should be re-simulated.

17. Eastern Interconnection inter-area oscillatory behavior should be further investigated by NERC, including the testing of large resource loss analysis for IFRO validation.

Findings

1. Analysis of data submitted by the Balancing Authorities during the field trial indicates that a single-event-based compliance measure is unsuitable for compliance evaluation when based on data that has the large degree of variability demonstrated by the field trial.

2. Analysis of data submitted by the Balancing Authorities during the field trial confirms that the sample size selected (a minimum of 20–25 frequency events) is sufficient to stabilize the result and alleviate the perceived problem associated with outliers in the measurement of Balancing Authority frequency response performance.

3. There is a strong positive correlation between Eastern Interconnection load and frequency response for the 2009–2011 events. On average, when interconnection load changes by 1,000 MW, frequency response changes by 3.5 MW/0.1Hz.

4. Pre-disturbance frequency (Value A) is a statistically significant contributor to the variability of frequency response for the Eastern Interconnection. The expected (mean of the sample) frequency response for events where Value A is greater than 60 Hz is 2,188 MW/0.1 Hz versus 2,513 MW/0.1 Hz for events where Value A is less than or equal to 60 Hz based on data from 2009 through April 2012.

5. There is a statistically significant seasonal (summer/not summer) correlation to the variability of frequency response for the Eastern Interconnection. The expected frequency response for summer (June–August) frequency events is 2,598 MW/0.1 Hz versus 2,271 MW/0.1 Hz for non-summer events based on data from 2009 through April 2012.

6. The difference in average frequency response between on-peak events and off-peak events is not statistically significant for the Eastern Interconnection and could occur by chance.

Frequency Response Overview

To understand the role frequency response plays in system reliability, it is important to understand the different components of frequency control and the individual components of Primary Frequency Control (also known as frequency response). It is also important to understand how those individual components relate to each other.

Frequency Control

Frequency control can be divided into four overlapping windows of time:

Primary Frequency Control (frequency response) – Actions provided by the interconnection to arrest and stabilize frequency in response to frequency deviations. Primary Control comes from automatic generator governor response, load response (typically from motors), and other devices that provide an immediate response based on local (device-level) control systems.

Secondary Frequency Control – Actions provided by an individual Balancing Authority or its Reserve Sharing Group to correct the resource-load unbalance that created the original frequency deviation, which will restore both Scheduled Frequency and Primary frequency response. Secondary Control comes from either manual or automated dispatch from a centralized control system.

Tertiary Frequency Control – Actions provided by Balancing Authorities on a balanced basis that are coordinated so there is a net-zero effect on area control error (ACE). Examples of Tertiary Control include dispatching generation to serve native load, economic dispatch, dispatching generation to affect interchange, and re-dispatching generation. Tertiary Control actions are intended to replace Secondary Control Response by reconfiguring reserves.

Time Control – This includes small offsets to scheduled frequency to keep long-term average frequency at 60 Hz.

Primary Frequency Control – Primary Frequency Response

Primary Frequency Control, also known generally as primary frequency response, is the first stage of frequency control and is the response of resources and load to arrest local changes in frequency. Primary frequency response is automatic, is not driven by any centralized system, and begins within seconds after the frequency changes, rather than minutes. Different resources, loads, and systems provide primary frequency response with different response times, based on current system conditions such as total resource/load mix and characteristics.

The NERC Glossary of Terms defines Frequency Response[15] in two parts:

- **Equipment** – The ability of a system or elements of the system to react or respond to a change in system frequency.

- **System** – The sum of the change in demand, plus the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 hertz (MW/0.1 Hz).

Because the loss of a large generator is much more likely than a sudden loss of an equivalent amount of load, frequency response is typically discussed in the context of a loss of generation.

NOTE: For purposes of this report, the term "frequency response" is considered to be the overall response measured between T+20 and T+52 seconds, as used in the BAL-003-1 draft standard.

Frequency Response Illustration

Many components are included within the defined frequency response. The following simplified example graphically illustrates those components of frequency response and how they react to changes in system frequency. The example is presented as an energy balance problem for the interconnection. It is not intended to be a treatise on governors or other turbine-generator controls or the internal machine dynamics associated with those control actions. For additional information on those topics, see the References on Rotating Machines section in Appendix L.

The example is based on an assumed disturbance event due to the sudden loss of 1,000 MW of generation. Although a large event is used to illustrate the response components, even small events can result in similar reactions or responses. The magnitude of the event only affects the shape of the curves on the graph; it does not obviate the need for frequency response.

The loss of generation is illustrated by the black power deficit line using the MW scale on the left. The interconnection frequency is illustrated in red, using the hertz (Hz) scale on the right. The interconnection frequency is assumed to be 60 Hz when the disturbance occurs.

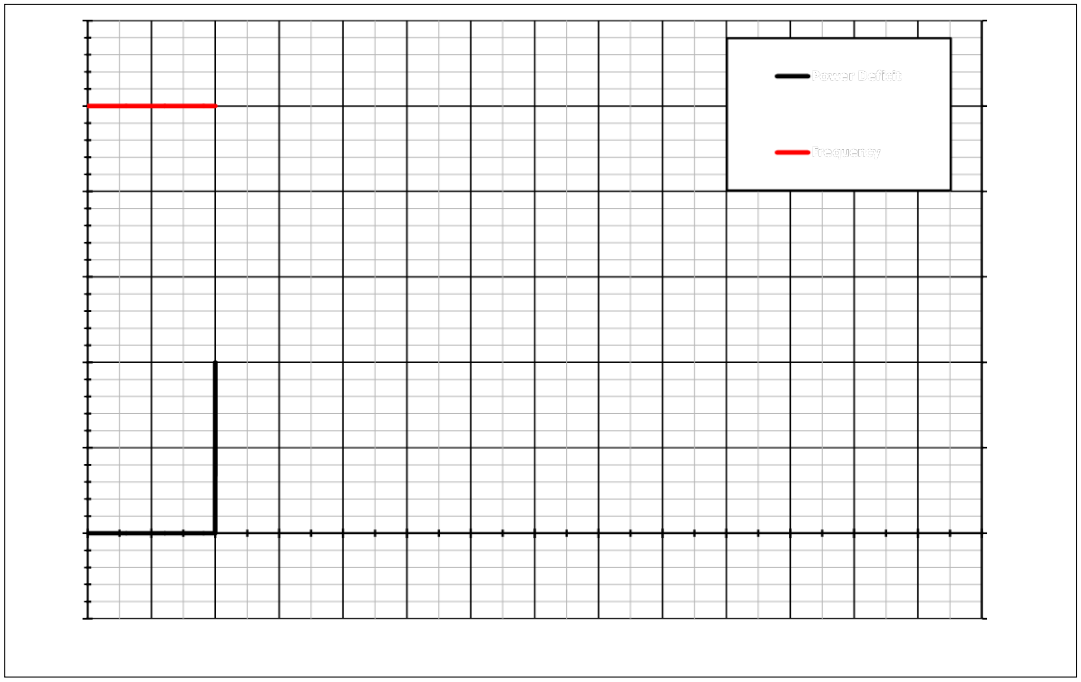
Figure 1 shows the tripping of a 1,000 MW generator. Even though the generation has tripped and power injected by the generator has been removed from the interconnection, the loads across the system continue to use the same amount of power. The Law of Conservation of Energy[16] requires that the 1,000 MW must be supplied to the interconnection if the energy balance is to be conserved. That 1,000 MW of balancing power is provided by extracting it from the kinetic energy stored as inertial energy in the rotating mass of all of the synchronized turbine-generators and motors on the interconnection. It is produced by the slowing of the spinning inertial mass of rotating equipment on the interconnection that both releases the stored kinetic energy and reduces the frequency of the interconnection. The extracted energy

[15] Capitalized as referenced in the NERC Glossary of Terms; lowercased otherwise.

[16] The "Law of Conservation of Energy" is applied here in the form of power. If energy must be conserved, then power—which is the first derivative of energy with respect to time—must also be conserved.

supplies the "balancing inertia"[17] power required to maintain the power and energy balance on the interconnection.

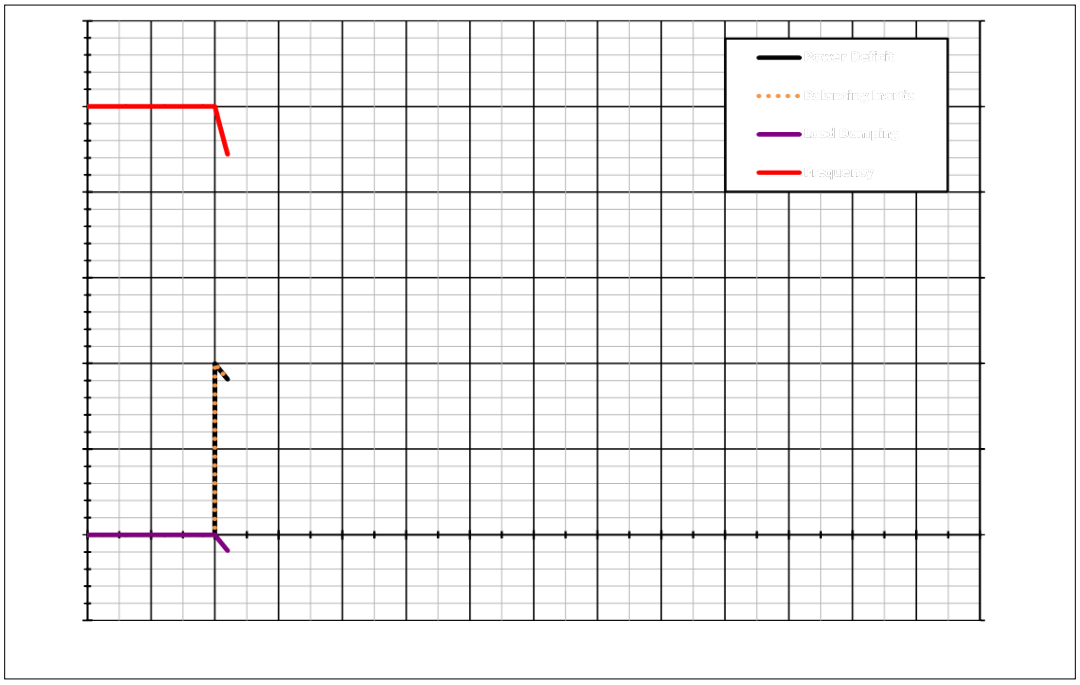
Figure 1: Loss of a 1,000 MW Generator



As this balancing power from inertia is used, the speed of the rotating equipment on the interconnection declines, resulting in a reduction of the interconnection frequency. Synchronously operated motors contribute to load damping; adjustable or variable speed drive motors are effectively decoupled from the interconnection frequency through their electronic controls, and they do not contribute to load damping. In general, any load that does not change with interconnection frequency (such as resistive loads) will not contribute to load damping or frequency response. The balancing inertia is illustrated in figure 2 by the orange dots, which represent the balancing inertia power that exactly overlays and offsets the power deficit. At this point in the example, no other energy injection has occurred through any governor control action.

[17] The term "balancing inertia" is coined here from the terms "inertial frequency response" and "balancing energy." Inertial frequency response is a common term used to describe the power supplied for this portion of the frequency response, and balancing energy is a term used to describe the market energy supposedly purchased to restore energy balance.

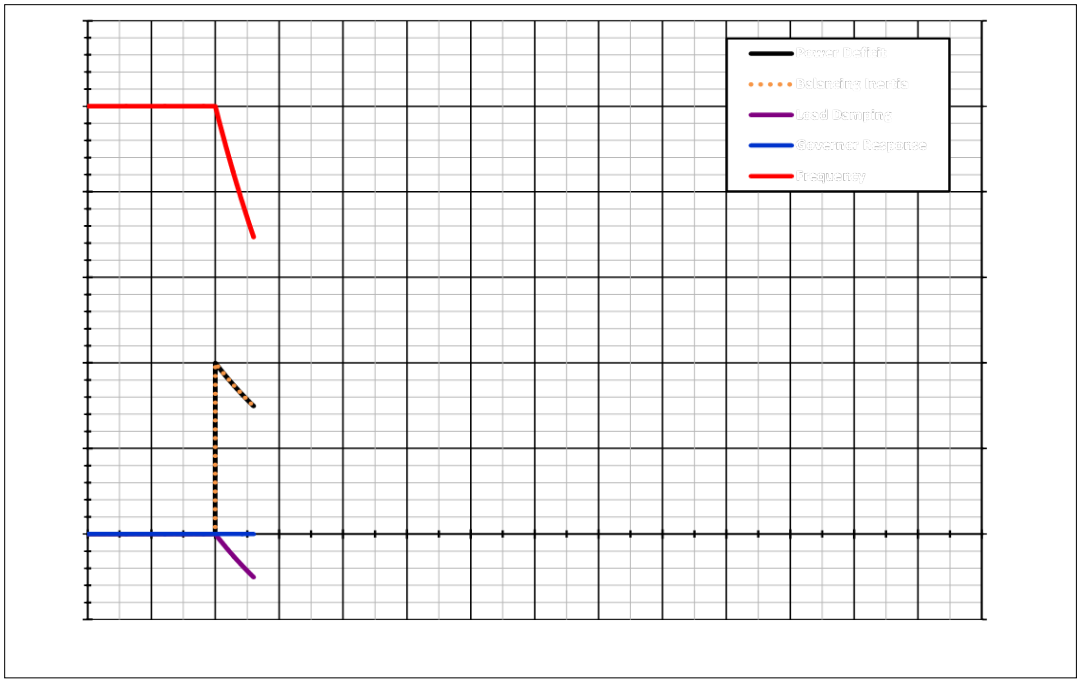
Figure 2: Inertial Energy Extracted from Rotating Mass of Generation and Synchronous Motor Load



As the rotating machines slow down (reflected as a decline of frequency), the generator governors, which are the controls that "govern" the speed of the generator turbines, sense this as a change in turbine speed. In this example, the change in frequency will be used to reflect this control parameter. Governor action then takes physical action, such as injecting more gas into a gas turbine, opening steam valves wider on a steam unit (also injecting more fuel into the boiler), or opening the control gates wider on a hydraulic turbine. This control action results in more combusted gases, steam, or water to impart more mechanical energy to the shaft of the turbine to increase its speed. The turbine shaft is coupled to the generator, where it is converted into additional electric energy. The process of the turbine slowing, the detection of change in speed, and the injection of additional mechanical energy is not instantaneous.

Until the additional mechanical energy can be injected, the frequency continues to decline, due to the ongoing extraction of balancing power from the inertial energy of the rotating turbine-generators and synchronous motors on the interconnection. As frequency continues to decline, the reduction in load also continues as the effect of load damping continues to reduce the load.

Figure 3: Time Delay of Governor Response

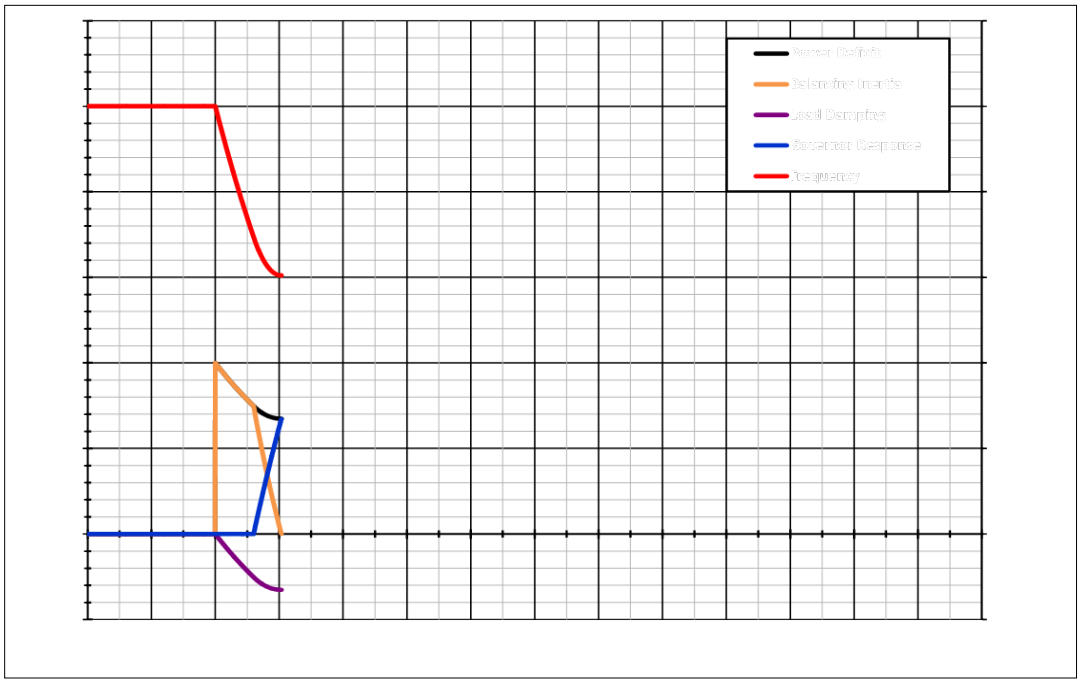


During the initial seconds of the disturbance event, the primary frequency response from the turbine governors has not yet influenced the frequency decline. For this example, primary frequency response from governors that injects additional energy into the system is reflected by the blue line (in MW) on figure 3.

After a short time delay, the governor response begins to increase rapidly in response to the initial decline in frequency, as illustrated in figure 4. In order to arrest the frequency decline, the governor response must offset the power deficit and replace the balancing power that had extracted inertial energy from the rotating machines of the interconnection. At this point in time, the balancing power from inertia is reduced to zero as it is replaced by the governor response. That replacement is shown as the crossing of the orange and blue lines in figure 4. The point at which the frequency decline is arrested is called the nadir, or Point C, and frequency response calculated to that point is "arrested frequency response."

If the time delay associated with the delivery of governor response is reduced, the amount of balancing power from inertia required to limit the change in frequency for the disturbance event can also be reduced. This supports the conclusion that balancing power from inertia is required to manage the time delays associated with the delivery of primary frequency response. Not only is the rapid delivery of primary frequency response important, but so is the shortening of the time delay associated with its delivery.

Figure 4: Governor Response Replaces Balancing Power from Inertia and Arrests Frequency Decline



The above components are related to the length of time before the initial delivery of primary frequency response from governors begins and how much of the response is delivered before the frequency change is arrested.

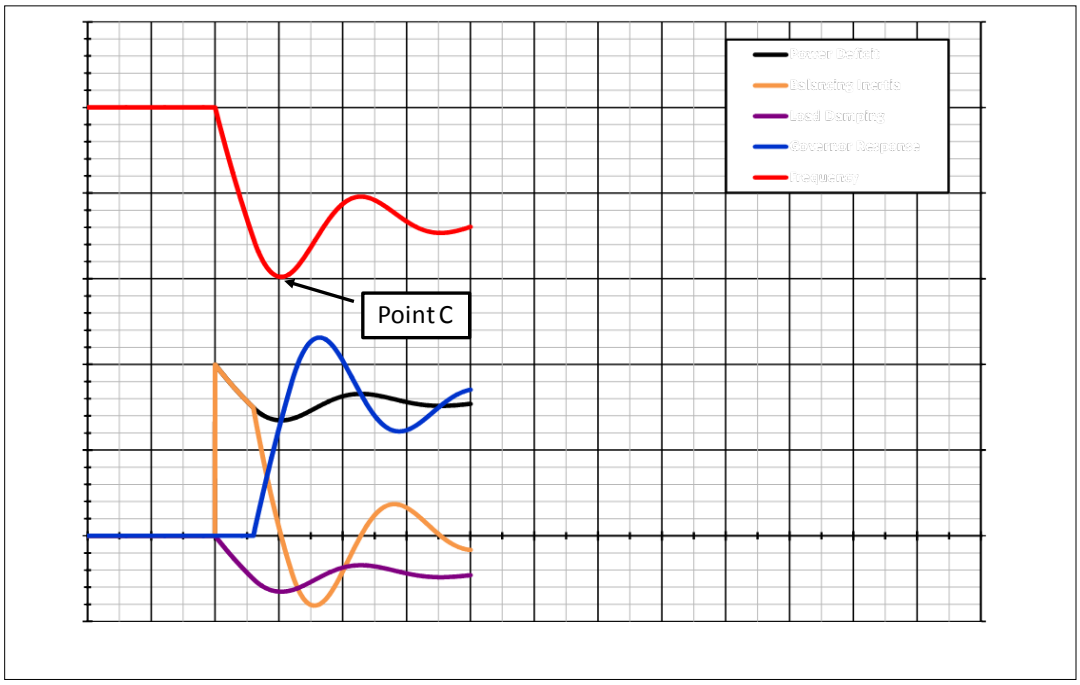
From a system standpoint during this time delay, the amount of inertia on the interconnection, which determines the amount of energy available to be extracted from rotating machines, determines the slope of the frequency decline: the less inertia there is, the steeper the slope. This is important in the relationship between the balancing power from inertia and the time delay associated with the governor response. For a given time delay in primary frequency response from governors, the steeper the slope, the lower frequency will dip before it is arrested. Conversely, for a given balancing power from inertia and slope of frequency decline, the faster governor response can be provided, the sooner the frequency decline is arrested, making the nadir less severe.

Therefore, as traditional rotating generators are replaced by electronically coupled resources, such as wind turbines and solar voltaic resources (which provide less overall system inertia), the speed of delivery of governor response should increase, or other methods should be provided that support fast-acting energy injection to minimize the depth of frequency excursions.

The arrested frequency is normally the minimum (maximum for load loss events) frequency that will be experienced during a disturbance event. This minimum frequency is the frequency that is of concern from a reliability perspective. The goal is to arrest the frequency decline so frequency remains above the under-frequency load shedding (UFLS) relays with the highest settings so that load is not tripped. Frequency response delivered after frequency is arrested at

this minimum provides less reliability value than frequency response delivered before Point C, but greater value than secondary frequency control power and energy that is delivered minutes later.

Figure 5: Post-Disturbance Transient Period (0 to 20 seconds)



Once the frequency decline is arrested, the governors continue to respond because of the time delay associated with the governor action. This results in the frequency partially recovering from the minimum arrested value and results in some oscillating transient that follows the minimum frequency (arrested frequency) until power flows and frequency settle during the transient period, which typically ends around 20 seconds after start of the disturbance event. This post-disturbance transient period is shown in figure 5.

The total disturbance event is illustrated in figure 6. Frequency and power contributions stabilize at the end of the transient period. Frequency response calculated from data measured during this settled period is called the "settled frequency response." The settled frequency response is the measure used as an estimator for determining the Frequency Bias[18] setting used in the automated generator control (AGC) systems of the energy management systems (EMS) in energy control centers.

[18] As defined in the NERC Glossary: "A value, usually expressed in megawatts per 0.1 hertz (MW/0.1 Hz), associated with a Balancing Authority Area that approximates the Balancing Authority Area's response to Interconnection frequency error."

Figure 6: Disturbance Event Frequency Excursion

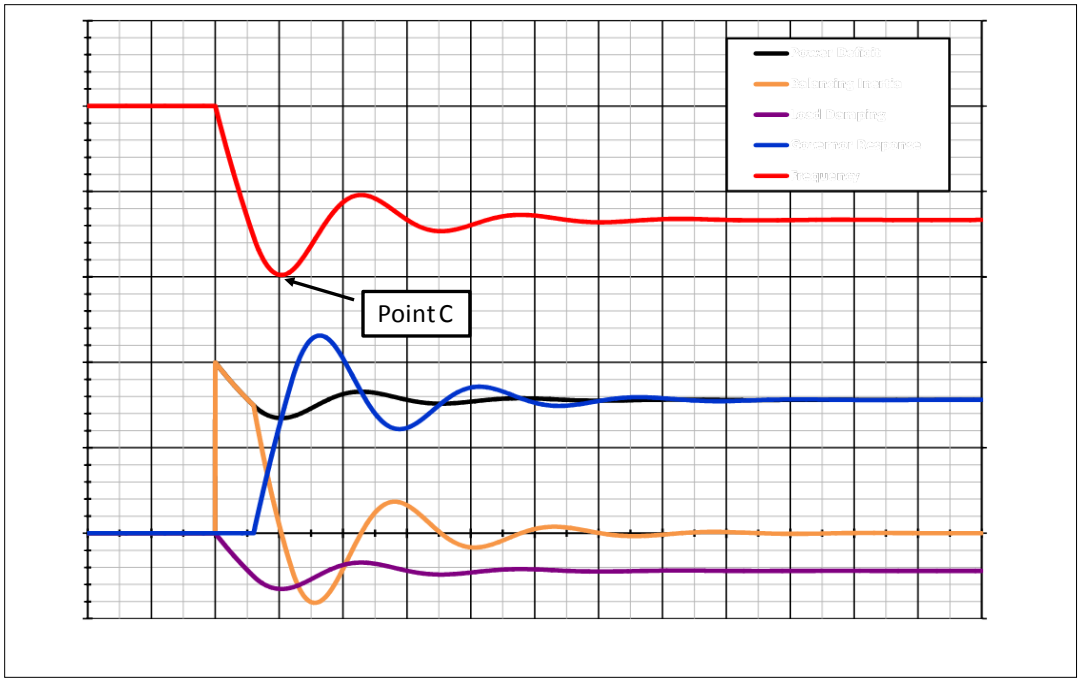


Figure 7: Averaging Periods used for Measuring Frequency Response

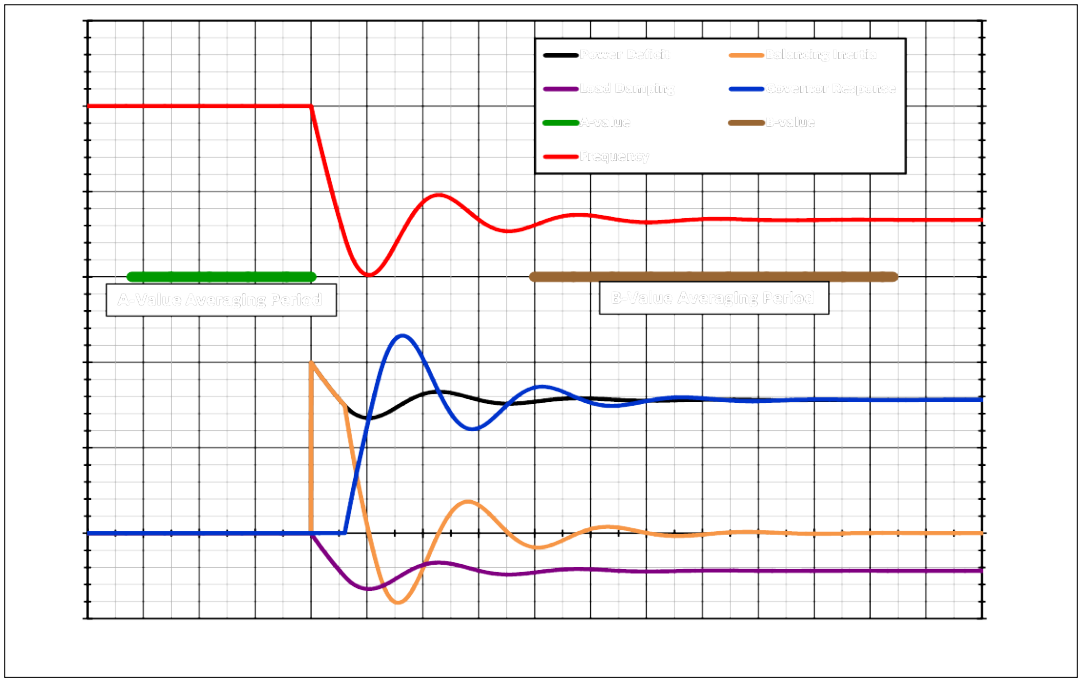

Figure 7 shows the averaging periods used to calculate[19] the pre-disturbance Value A frequency averaging period (T-16 through T+0 seconds) and the post-disturbance Value B frequency averaging period (T+20 through T+52 seconds) used to calculate the settled frequency response. The length of those periods is based on the length of the system control and data acquisition (SCADA) scan rates of the energy management systems (EMS) of the Balancing Authorities.

The calculation of the Value A and Value B frequencies began with the assumption that a 6-second scan rate was the source of the data. Once the averaging periods for a 6-second SCADA scan rate were selected, the averaging periods for the other scan rates were selected to provide as much consistency as possible between Balancing Authorities with different scan rates.

The Value A frequency was initially defined as the average of the two scans immediately prior to the frequency event. All other averaging periods were then selected to be as consistent as possible with this 12-second average scan from the 6-second scan rate method. In addition, the "actual net interchange immediately before Disturbance" was then defined as the average of the same period and same scans as used for Value A averaging.

The Value B frequency was then selected to be an average as long as the average of 6-second scan data as possible, that would not begin until most of the hydro governor response had been delivered, and would end before significant Automatic Generation Control (AGC) recovery response had been initiated as indicated by a consistent frequency restoration slope. The "actual net interchange immediately after Disturbance" was then similarly defined as the average of the same period and same scans as used for the Value B.

Balancing Authority Frequency Response

Disturbances can cause the frequency to either increase from loss of load or decrease from loss of generation; frequency response characteristics of Balancing Authorities should be evaluated for both types of events.

Accurate measurement of frequency response for an interconnection or for individual Balancing Authorities is difficult unless the frequency deviation resulting from a system disturbance is significant. Therefore, it is better to analyze response only when significant frequency deviations occur.

Frequency response considers the following elements of an interconnected transmission system:

1. **Frequency Response Characteristic (FRC)** – For any change in generation/load balance in the interconnection, a frequency change occurs. Each Balancing Authority in the interconnection will respond to this frequency change through:
    - a load change that is proportional to the frequency change due to the load's FRC, and

[19] As proposed in Standard BAL-003-1 – Frequency Response.

- a generation change that is inverse to the frequency change due to turbine governor action. The net effect of these two actions is the Balancing Authority's response to the frequency change; that is, its FRC. The combined response of all Balancing Authorities in the interconnection will cause the interconnection frequency to settle at some value different from the pre-disturbance value. It will not return frequency to the pre-disturbance value because of the turbine governor droop characteristic. Frequency will remain different until the Balancing Authority with the generation/load imbalance (referred to as the "Contingent Balancing Authority") corrects that imbalance, thus returning the interconnection frequency to its pre-disturbance value.

2. **Response to Internal and External Generation/Load Imbalances** – Most of a Balancing Authority's frequency response will be reflected in a change in its actual net interchange. By monitoring the frequency error (the difference between actual and scheduled frequency) and the difference between actual and scheduled interchange, using its response to frequency deviation, a Balancing Authority's automatic generation control (AGC) can determine whether the imbalance in load and generation is internal or external to its system. If internal, the Balancing Authority's AGC should correct the imbalance. If external, the Balancing Authority's AGC should allow its generator governors to continue responding (preserved by its frequency bias contribution in its ACE equation) until the contingent Balancing Authority corrects its imbalance, which should return frequency to its pre-disturbance value.

3. **Frequency Bias versus Frequency Response Characteristic (FRC)** – The Balancing Authority should set its bias setting in its AGC ACE equation to match its FRC. In doing so, the Balancing Authority's bias contribution term would exactly offset the tie line flow error (Ni_A – Ni_S) of the ACE that results from governor action following a frequency deviation on the interconnection. The following sections discuss the effects of bias settings on control action and explain the importance of setting the bias equal to the Balancing Authority's FRC. The discussion explains the control action on all Balancing Authorities external to the contingent Balancing Authority (the Balancing Authority that experienced the sudden generation/load imbalance) and on the contingent Balancing Authority itself.

   While this discussion deals with loss of generation, it applies equally to loss of load, or any sudden contingency resulting in a generation/load mismatch. Each Balancing Authority's frequency response will vary with each disturbance because generation and load characteristics change continuously. This discussion also assumes that the frequency error from 60 Hz was zero (all ACE values were zero) just prior to the sudden generation/load imbalance.

4. **Effects of a Disturbance on all Balancing Authorities External to the Contingent Balancing Authority** – When a loss of generation occurs, an interconnection frequency error will occur as rotating kinetic energy from the generators of the interconnection is expended, slowing the generators throughout the interconnection. All Balancing Authorities' generator governors will respond to the frequency error and increase the

output of their generators (increase speed) accordingly. This will cause a change in the Balancing Authorities' actual net interchange. In other words, the Actual Net Interchange (Ni_A) will be greater than the Scheduled Net Interchange (Ni_S) for all but the contingent Balancing Authority, and the result is a positive flow out of the non-contingent Balancing Authorities. The resulting tie flow error ($Ni_A - Ni_S$) will be counted as Inadvertent Interchange.

If the Balancing Authorities were using only tie line flow error (i.e., flat tie control ignoring the frequency error), this non-zero ACE would cause their AGC to reduce generation until Ni_A was equal to Ni_S, returning their ACE to zero. However, doing this would not help arrest interconnection frequency decline, because the Balancing Authorities would not be helping to temporarily replace some of the generation deficiency in the interconnection. With the tie line bias method, the Balancing Authorities' AGC should allow their governors to continue responding to the frequency deviation until the contingent Balancing Authority replaces the generation it has lost.

In order for the AGC to allow governor action to continue to support frequency, a frequency bias contribution term is added to the ACE equation to counteract the tie flow error. This bias contribution term is equal in magnitude and opposite in direction to the governor action and should ideally be equal to each Balancing Authority's frequency response characteristic measured in MW/0.1 Hz. Then, when multiplied by the frequency error, the bias should exactly counteract the tie flow error portion of the ACE calculation, allowing the continued support of the generator governor action to support system frequency.

In other words, $BiasContributionTerm = 10B(f_A - f_S)$. ACE will be zero, and AGC will not read just generation.

The ACE equation is then:

$$ACE = (Ni_A - Ni_S) - 10B(f_A - f_S) - I_{ME}$$

Where:

- The factor 10 converts the bias setting (B) from MW/0.1 Hz to MW/Hz.
- I_{ME} is meter error correction estimate; this term should normally be very small or zero.

NOTE: Although frequency response and bias are often discussed as positive values (such as "our bias is 50 MW/0.1 Hz"), frequency response and bias are actually negative values.

If the bias setting is greater than the Balancing Authority's actual frequency response characteristic, then its AGC will increase generation beyond the primary frequency response from governors, which further helps arrest the frequency decline, but increases Inadvertent Interchange. Likewise, if the bias contribution term is less than

the actual FRC, its AGC will reduce generation, reducing the Balancing Authority's contribution to arresting the frequency change. In both cases, the resultant control action is unwanted.

5. **Effects of a Disturbance on the Contingent Balancing Authority** – In the contingent Balancing Authority where the generation deficiency occurred, most of the replacement power comes from the interconnection over its tie lines from the frequency response contributions of the other Balancing Authorities in the interconnection. A small portion will be made up internally from the contingent Balancing Authority's own governor response. In this case, the difference between Ni_A and Ni_S for the contingent Balancing Authority is much greater than its frequency bias component. Its ACE will be negative (if the loss is generation), and its AGC will begin to increase generation.

   - Ni_A – drops by the total generation lost less the contingent Balancing Authority's own primary frequency response from governors
   - Ni_S – does not change

   The contingent Balancing Authority must take appropriate steps to reduce its ACE to zero or pre-disturbance ACE if ACE is negative within 15 minutes of the contingency. (Reference: formerly Operating Criterion II.A.) The energy supplied from the interconnection is posted to the contingent Balancing Authority's inadvertent balance.

6. **Effects of a Disturbance on the Contingent Balancing Authority with a Jointly Owned Unit** – In the contingent Balancing Authority where the generation deficiency occurred on a jointly owned unit (with dynamically scheduled shares being exported), the effect on the tie line component ($Ni_A – Ni_S$) of their ACE equation is more complicated. The Ni_A drops by the total amount of the generator lost, while the Ni_S is reduced only by the dynamic reduction in the shares being exported.

   - Ni_A – drops by the total generation lost less the contingent Balancing Authority's own primary frequency response from governors
   - Ni_S – decreases by the reduction in dynamic shares being exported

   The net effect is that the tie line bias component only reflects the contingent Balancing Authority's share of the lost generation. Most of the replacement power comes from the interconnection over its tie lines from the frequency bias contributions of the other Balancing Authorities in the interconnection.

7. **Effects of a Disturbance on the Non-contingent Balancing Authority with a Jointly Owned Unit** – In the non-contingent Balancing Authority where the generation deficiency occurred on a jointly-owned unit in another Balancing Authority (with dynamically scheduled shares being exported), the effect on the tie line component ($Ni_A – Ni_S$) of their ACE equation is also complicated. The Ni_A increases by the Balancing Authority's own primary frequency response from governors, while the Ni_S is reduced only by the dynamic reduction in the shares being imported.

- Ni_A – increases by the Balancing Authority's own primary frequency response from governors
- Ni_S – decreases by withdrawn dynamic shares of the jointly-owned unit

The net effect is that the tie line bias component only reflects the contingent Balancing Authority's share of the lost generation. Most of the replacement power comes from the interconnection over its tie lines from the frequency bias contributions of the other Balancing Authorities in the interconnection.

Historical Frequency Response Analysis

History of Frequency Response and its Decline

Interconnection frequency response has been a subject of industry interest and attention since the first two electric systems became interconnected and the concept of frequency bias was adopted. In 1942, the first test to determine the system's load/frequency characteristic was conducted for use in setting bias control. As interconnected systems grew larger and the characteristics of load and generation changed, it became apparent that guidelines were needed regarding frequency response to avoid one system imposing undue frequency regulation burdens on its interconnected neighbors. During the 1970s and 1980s, NERC's Performance Subcommittee (now the Resources Subcommittee of the Operating Committee), which is charged with monitoring the control performance of the interconnections, observed that generators' governor responses to frequency deviations had been decreasing, especially in the Eastern Interconnection. The result was quite noticeable during large generation losses where the frequency deviation was not arrested as quickly as it once was. The industry did not initially recognize that power systems operations could significantly influence primary frequency response.[20]

In 1991, NERC's Performance Subcommittee approached the Electric Power Research Institute (EPRI) with a request to fund and manage a study of the apparent decline in governor response in the interconnections. EPRI agreed and in turn contracted with EPIC Engineering to perform this study. The conclusions were captured in a joint EPRI/NERC report, "Impacts of Governor Response Changes on the Security of North American Interconnections."[21] These studies indicated that the frequency response of the interconnections was declining at rates greater than would be expected with the growth of demand and generating capacity.[22] Although frequency response was declining, the opinion of experts at the time was that the decline had not reached a point at which reliability was being compromised.

The NERC Resources Subcommittee proposed a frequency response standard for comment in 2001. In response to these comments, the Frequency Task Force of the NERC Resources Subcommittee published a Frequency Response Standard white paper[23] intended to create an understanding of the need for a frequency response standard and the technical and economic drivers motivating its development. The paper documented and discussed the decline observed in frequency response in the Eastern and Western Interconnections.

[22] *See* EPRI Report TR-101080, *Impacts of Governor Response Changes on the Security of North American Interconnections*, October 1992 ("An analysis of the 14 Frequency Response Characteristics Surveys conducted by NERC over the 1971 to 1993 period showed that the Frequency Response in percent MW/O. 1Hz has deteriorated. This value in 1971 was between 2.25 and 3.25% (depending on the area) and by 1993 had dropped to 0.75 and 1.25 %.").

Projections of Frequency Response Decline

In August 2011, the Transmission Issues Subcommittee[24] of the NERC Planning Committee completed an analysis titled "Interconnection Criteria for Frequency Response Requirements – Determination of Interconnection Frequency Response Obligations."[25] The analysis included comparisons of various Resource Contingency Protection Criteria for loss of resources, including largest potential loss-of-resource event (N-2), the largest total generating plant with common voltage switchyard, and the largest loss of generation in the interconnection in the last 10 years. Also examined in that analysis were the various other factors that must be considered in an IFRO determination: the highest under-frequency load shedding (UFLS) program setpoint within each interconnection, special consideration of demand-side frequency responsive programs in ERCOT, and a reliability margin to account for the variability of frequency due to items such as time error correction (TEC), variability of load, variability of interchange, variability of frequency over the course of a normal day, and other uncertainties. The proposed margin was analyzed using a probabilistic approach based on 1-minute frequency performance data for each interconnection. The Transmission Issues Subcommittee recommended the following IFROs for the four interconnections: Eastern: -1,875 MW/0.1 Hz; Western: -637 MW/0.1 Hz; Texas: -327 MW/0.1 Hz; and Québec: -113 MW/0.1 Hz. The Transmission Issues Subcommittee IFRO report was approved by the NERC Planning Committee in September 2011 and forwarded to the Standard Drafting Team for their consideration.

A similar report had been prepared by the Resources Subcommittee of the NERC Operating Committee in January 2011 titled "NERC Resources Subcommittee Position Paper on Frequency Response."[26] That report used similar Resource Contingency Protection Criteria but used the prevalent 59.5 Hz highest UFLS setpoint for the Eastern Interconnection and a lower 59.3 Hz UFLS setpoint for ERCOT. The Resources Subcommittee analysis also used a 25% reliability margin for all four interconnections. The Resources Subcommittee recommended the following IFROs for the four interconnections: Eastern: -1,406MW/0.1 Hz; Western: -685 MW/0.1 Hz; Texas: -286 MW/0.1 Hz; and Québec: -141 MW/0.1 Hz. The Resources Subcommittee position paper was approved by the Operating Committee in March 2011 and was considered by the Frequency Response Standard Drafting Team. NERC has been tracking the decline of frequency response in the Eastern Interconnection for several years.

[24] The Transmission Issues Subcommittee is now the System Analysis and Modeling Subcommittee (SAMS).

[26] Available here: http://www.nerc.com/docs/oc/rs/NERC%20RS%20Position%20Paper%20on%20Frequency%20Response%20Final%20(May%2027%202011).pdf.

Figure 8: Eastern Interconnection Mean Primary Frequency Response[27] (March 30, 2012)

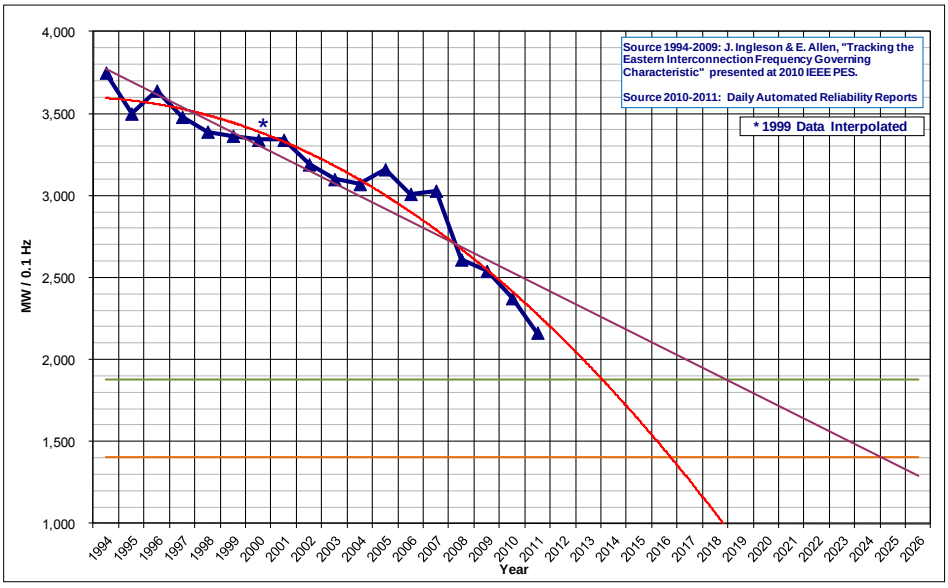

Figure 8 shows how frequency response has declined since 1994, as filed in NERC's "Motion for an Extension of Time of the North American Electric Reliability Corporation" (for the development of Standard BAL-003-1 – Frequency Response).[28] That request for extension of time was granted by FERC in its Order on Motion for an Extension of Time and Setting Compliance Schedule (Issued May 4, 2012).[29]

Comparing the proposed IFROs from those two studies, the Eastern Interconnection IFROs range from about 1,400 MW/0.1 Hz to about 1,900 MW/0.1 Hz, and the linear projection of the frequency response decline intercepts those target IFROs between 2019 and 2024. Even the more pessimistic polynomial projection of the decline intercepts the proposed IFROs between 2014 and 2016. This shows that there was still some time as of that filing for revising BAL-003-1 and responding to the decline in frequency response.

Figure 8 was revised shortly after the March 2012 filing in conjunction with revised frequency response calculation methods used in NERC's 2012 State of Reliability report (May 2012). Figure 9 reflects the revised frequency response calculations for 2009 through 2011.

[27] The Frequency Response data from 1994 through 2009 displayed in figure 2 is from a report by J. Ingleson & E. Allen, Tracking the Eastern Interconnection Frequency Governing Characteristic that was presented at the 2010 IEEE.

[28] Filing available at: http://www.nerc.com/files/MotionExtTime_RM06-16_03302012.pdf

[29] Order available at: http://www.nerc.com/files/Order_Motion_Extension_Time_Compliance_Sched_2012.5.4.pdf

Figure 9: Updated Eastern Interconnection Mean Primary Frequency Response (May 2012)

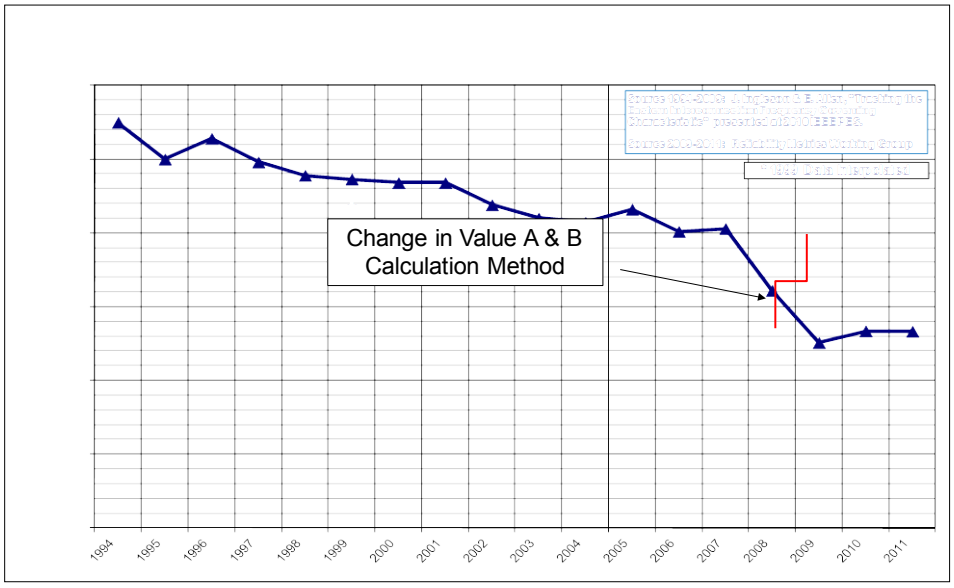

Figure 9 shows an improvement in frequency response in 2009 through 2011 due to alignment of the methods for calculation Values A and B. That method is consistent with the method being proposed in NERC Standard BAL-003-1. The method has since been further refined, as reflected in the Statistical Analysis of Frequency Response section of this report.

Figures 10–13 show the statistical analysis of the frequency response for 2009–2011 for the Eastern, Western, and ERCOT Interconnections from the 2012 State of Reliability report in box plot format (only 2011 data was available for the Québec Interconnection).

Figure 10: Eastern Interconnection Frequency Response Analysis for 2009–2011

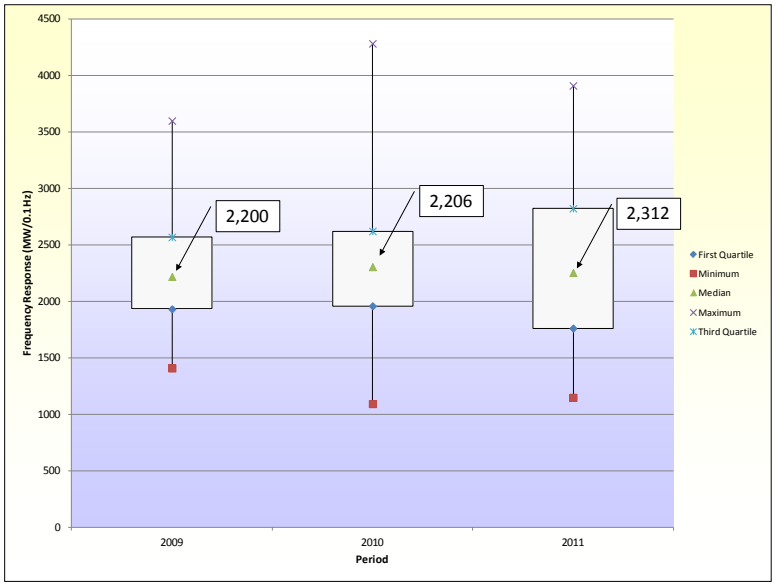

Figure 11: Western Interconnection Frequency Response Analysis for 2009–2011

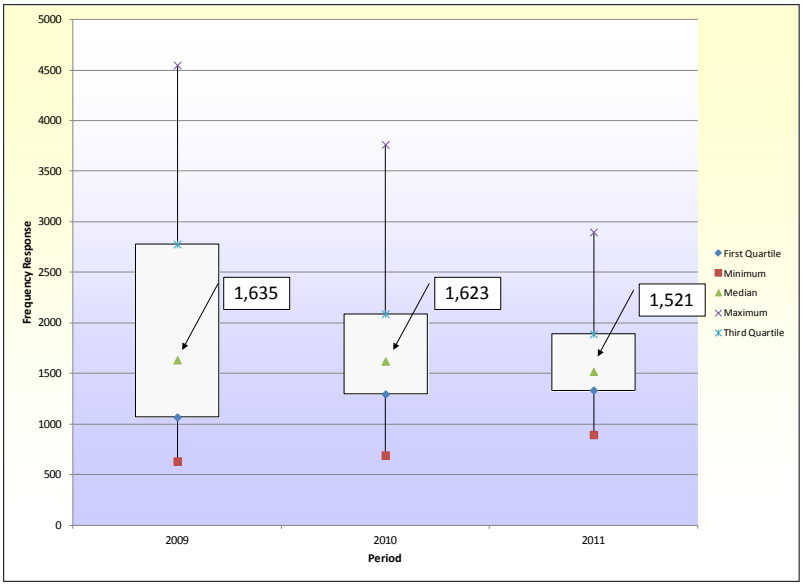

Figure 12: ERCOT Interconnection Frequency Response Analysis for 2009–2011

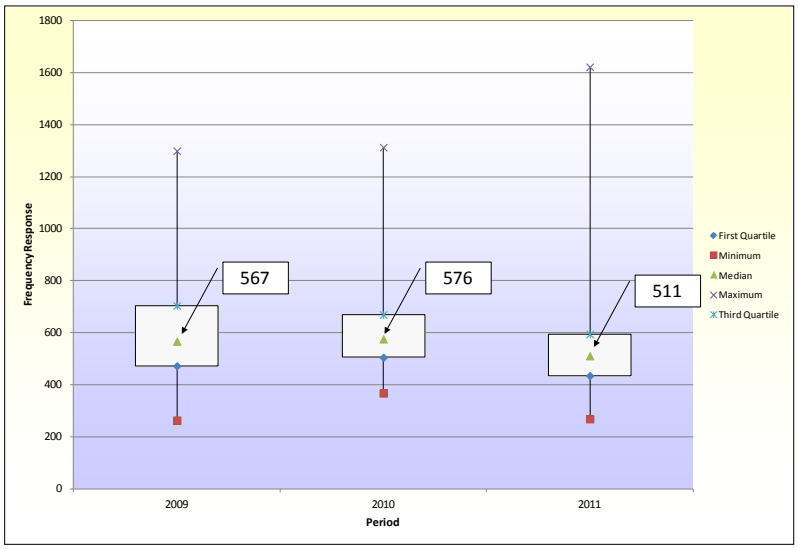
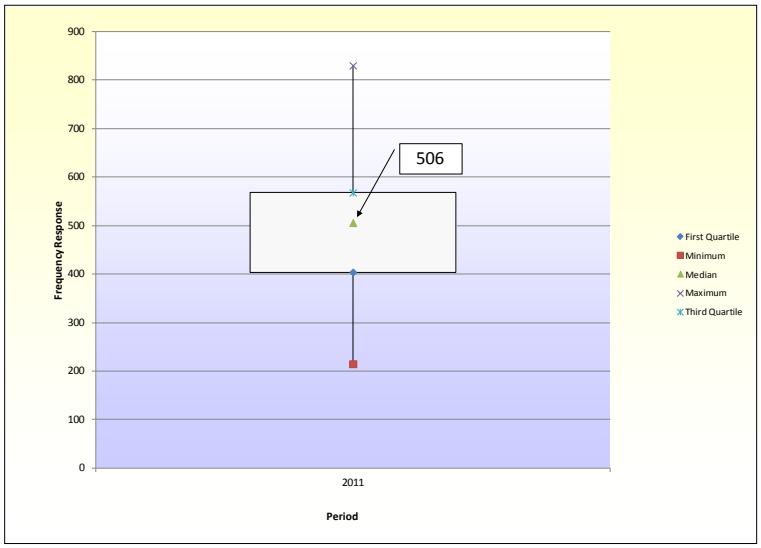


It is important to note the range of variability of the frequency response for each year. Additional events and modifications to the calculation methods for the A, B, and C values have been made since these values were calculated for the May 2012 report. The new values are reflected in the Statistical Analysis section of this report.

Figure 13: Québec Interconnection Frequency Response Analysis for 2011



Statistical Analysis of Frequency Response (Eastern Interconnection)

In July 2012, a statistical analysis of the frequency response of the Eastern Interconnection was performed for the calendar years 2009–2011 and the first three months of 2012. The size of the dataset was 163 (with 44 observations for 2009, 49 for 2010, 65 for 2011, and 5 for 2012).

Table 1: Statistical Analysis Dataset

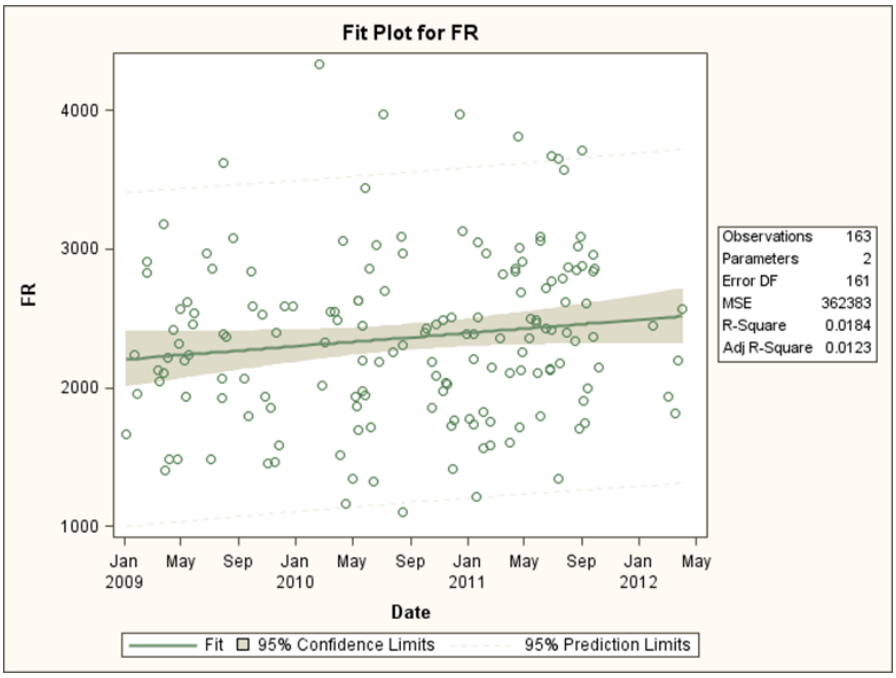
Sample Parameter	2009	2010	2011
Sample Size	44	49	65
Sample Mean	2,258.4	2,335.7	2,467.8
Sample Standard Deviation	522.5	697.6	593.7

The report on that analysis was updated in August and September 2012 and is contained in Appendix G. Its results are paraphrased here for brevity. For the analysis, frequency response pertains to the absolute value of frequency response.

Key Statistical Findings

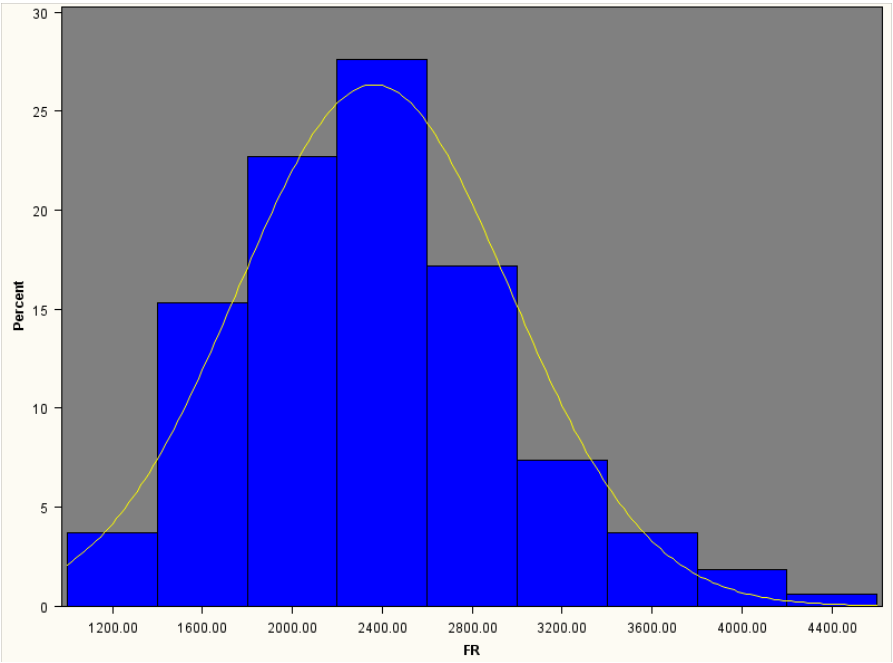
1. A linear regression equation with the parameters defined in Appendix G is an adequate statistical model to describe the relationship between time (predictor) and frequency response (responsive variable). The graph of the linear regression line and frequency response scatter plot is given in figure 14.

Figure 14: Linear Regression Fit Plot for Eastern Interconnection Frequency Response



2. The probability distribution of the whole frequency response dataset is approximately normal, with an expected frequency response of 2,363 MW/0.1 Hz and a standard deviation of 605.7 MW/0.1 Hz as shown in figure 15.

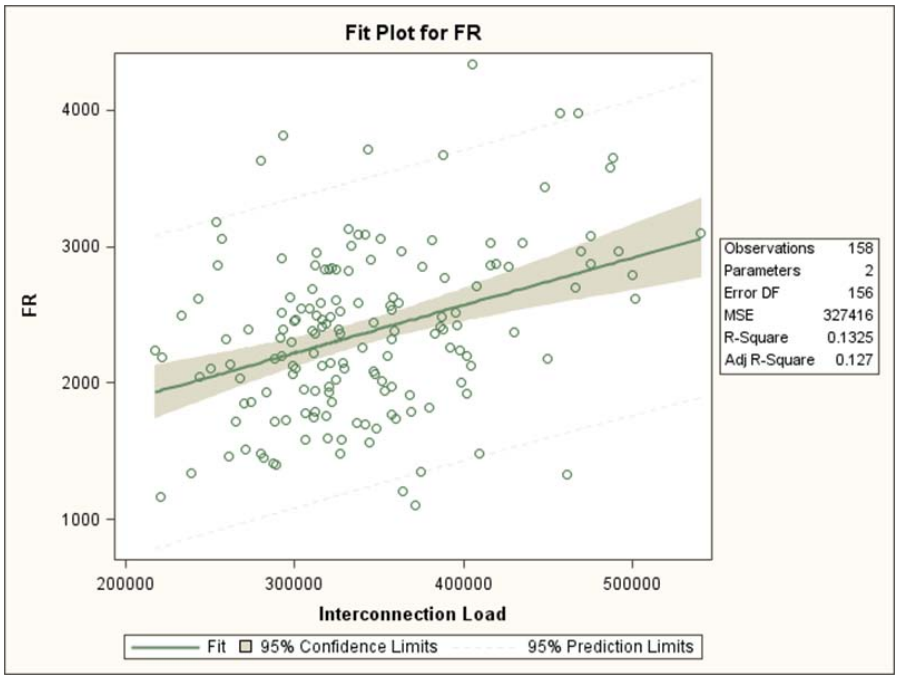
Figure 15: Probability Distribution Eastern Interconnection Frequency Response January 2009–April 2012



3. There is a statistically significant seasonal (summer/not summer) correlation to the variability of frequency response for the Eastern Interconnection. The expected frequency response (mean of the samples) for summer (June–August) frequency events is 2,598 MW/0.1 Hz versus 2,271 MW/0.1 Hz for non-summer events. This is attributable to at least two factors: higher load contribution to frequency response and increased generation dispatch of units with higher frequency response characteristics.

4. Pre-disturbance (average) frequency (Value A) is another statistically significant contributor to the variability of frequency response. The expected frequency response (mean of the samples) for events where Value A is greater than 60 Hz is 2,188 MW/0.1 Hz versus 2,513 MW/0.1 Hz for events where Value A is less than or equal to 60 Hz.

Figure 16: Linear Regression for Frequency Response and Interconnection Load



5. The difference in average frequency response between on-peak events and off-peak events is not statistically significant and could occur by chance. According to the NERC definition, Eastern Interconnection on-peak hours are designated as follows: Monday to Saturday from 07:00 to 22:00 hours (Central Time) excluding six holidays: New Year's Day, Memorial Day, Independence Day, Labor Day, Thanksgiving Day, and Christmas Day. Analysis showed that the on-peak/off-peak variable is not a statistically significant contributor to the variability of frequency response. There is a positive correlation of 0.06 between the indicator function of on-peak hours and frequency response; however, difference in average frequency response between on-peak events and off-peak events is not statistically significant and could occur by chance (P-value—the probability of obtaining a result at least as extreme—is 0.49).

6. There is a strong positive correlation of 0.364 between interconnection load and frequency response for the 2009–2011 events. On average, when interconnection load changes by 1,000 MW, frequency response changes by 3.5 MW/0.1 Hz.

   This correlation indicates a statistically significant linear relationship between interconnection load (predictor) and frequency response (response variable). Figure 16 shows the linear regression line and frequency response scatter plot. For the dataset, the regression line has a positive slope estimate of 0.00349; thus, the frequency response variable increases when interconnection load grows.

7. For the 2009–2011 dataset, five variables (time, summer, high pre-disturbance frequency, on-peak/off peak hour, and interconnection load) were involved in the statistical analysis of frequency response. Four of these—time, summer, on-peak hours, and interconnection load—have a positive correlation with frequency response (0.16, 0.24, 0.06, and 0.36, respectively), and the high pre-disturbance frequency has a negative correlation with frequency response (-0.26). The corresponding coefficients of determination R^2 (the square of correlation) indicate that about 2.6% in variability of frequency response can be explained by the changes in time, about 5.8% is seasonal, 0.4% is due to on-peak/off-peak changes, 13.3% is the effect of interconnection load variability, and about 6.9% can be accounted for by a high pre-disturbance frequency. However, the correlation between frequency response and on-peak hours is not statistically significant, with the probability of about 0.44 having occurred by mere chance (the same holds true for the corresponding R^2).

Table 2: Explanatory Variables for Eastern Interconnection Frequency Response

Variable X	Sample Correlation (X, FR)	P-Value	Linear Regression Statistically Significant	Coefficient of Determination R^2 (Single Regression)
Interconnection Load	0.36	<0.0001	Yes	13.3%
Value A > 60 Hz	-0.26	0.0008	Yes	6.9%
Summer/Not Summer	0.24	0.0023	Yes	5.8%
Date	0.16	0.044	Yes	2.6%
On-Peak Hours	0.06	0.438	No	N/A

Therefore, out of the five parameters, interconnection load has the biggest impact on frequency response followed by the indicator of high pre-disturbance frequency. A multivariate regression with interconnection load and starting frequency (Value A) greater

than 60 Hz as the explanatory variables for frequency response yields a linear model with the best fit (it has the smallest mean square error among the linear models with any other set of explanatory variables selected from the five studied). Together these two factors can account for about 20% of the variability in frequency response.

Frequency response is, therefore, affected by other parameters that have low correlation with those studied and account for the remaining share of frequency response variability, minimizing the random error variance.

Note that interconnection load is positively correlated with summer (0.55), on-peak hours (0.45), and time (0.20), but is uncorrelated with starting frequency greater than 60 Hz (P-value of the test on zero correlation is 0.90).

Frequency Response Withdrawal

Withdrawal of primary frequency response is an undesirable characteristic associated most often with digital turbine-generator control systems using setpoint output targets for generator output. These are typically outer-loop control systems that defeat the primary frequency response of the governors after a short time to return the unit to operating at a requested MW output.

Figure 17: Primary Response Sustainability

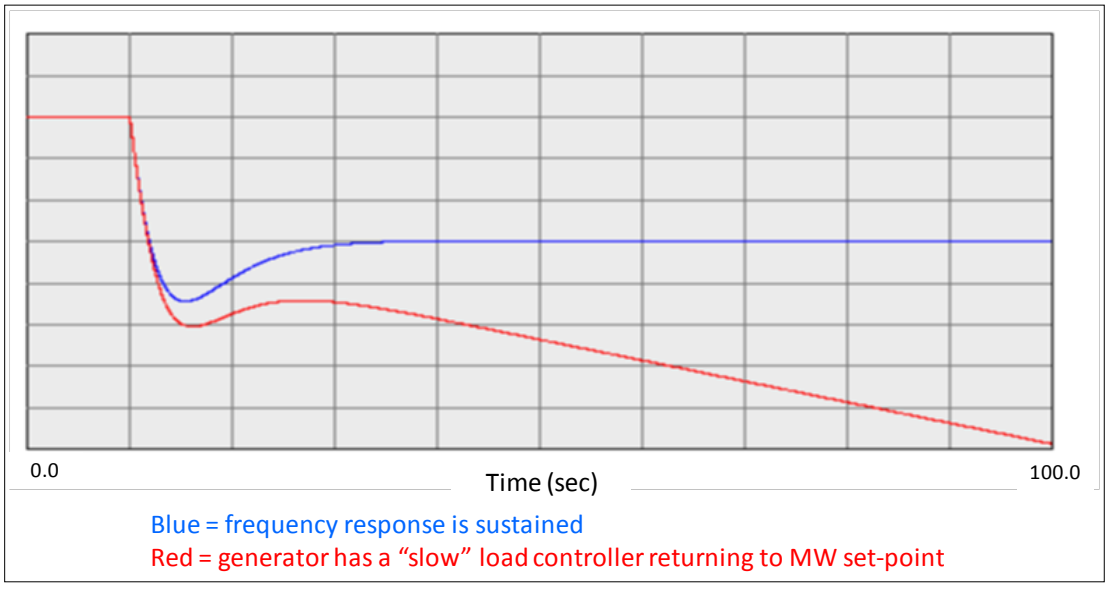


Figure 17 shows how the outer-loop control on a single machine would influence its ability to provide primary frequency response.

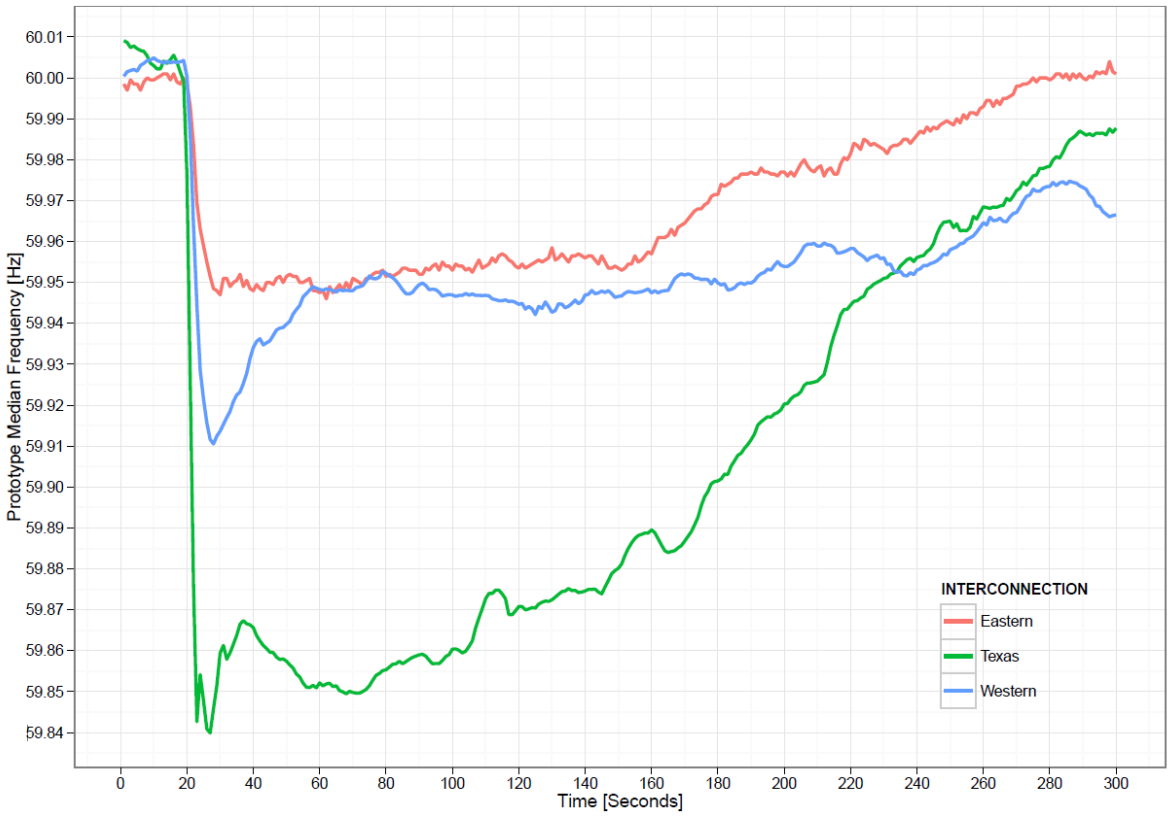
Some of the typical causes of the withdrawal are:

- Plant outer-loop control systems – driving the units to MW setpoints
- Unit characteristics

  - Plant incapable of sustaining primary frequency response
  - Governor controls overridden by other turbine/steam cycle controls
- Operating philosophies – operating characteristic choices made by plant operators
  - Desire to maintain highest efficiencies for the plant

The phenomenon is most prevalent in the Eastern Interconnection and can easily be seen in the comparison of the typical frequency response performance of the three interconnections (figure 18).

Figure 18: Typical Interconnection Responses for 2011[30]



Sustainability of primary frequency response becomes more important during light load conditions (nighttime) when there are generally fewer frequency-responsive generators on-line.

A number of the governor survey questions addressed the operational status and parameters of the governor fleet. The results of the survey show:

- About 90% of the generators were reported to have governors.

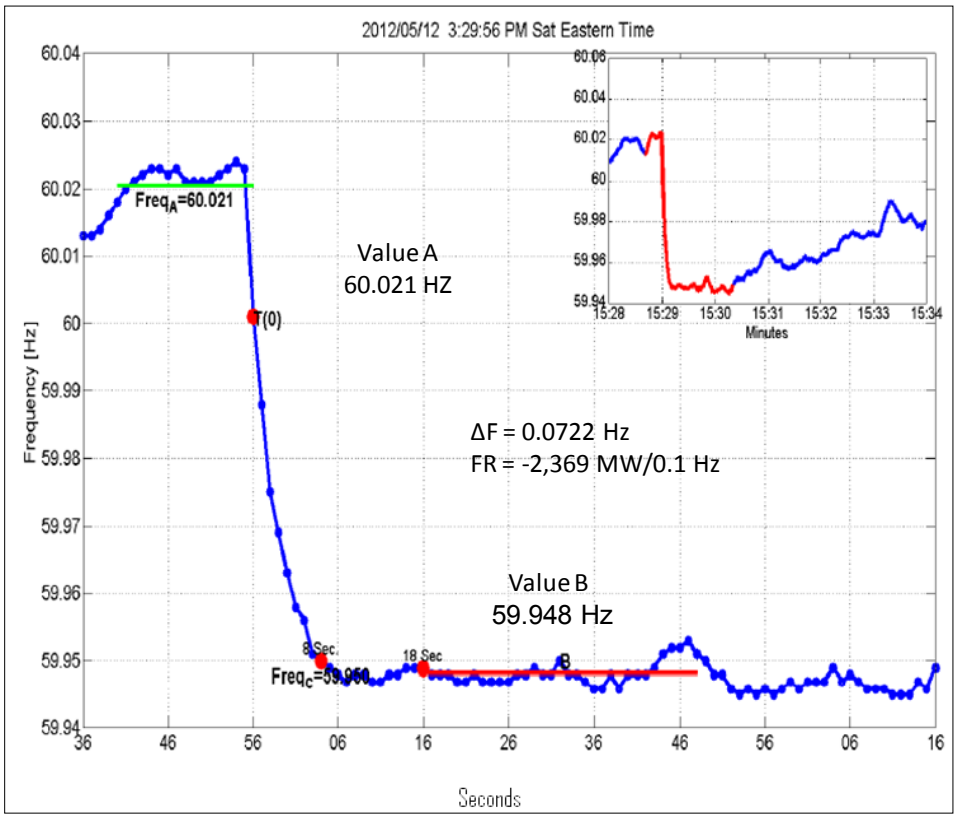
[30] NERC interconnections 2011 typical event frequency patterns using the median of the same second of each RS–FWG selected event – Revised: 09/26/12 provided by Advanced Systems Researchers.

- Virtually all (95–99% by interconnection) of the GOs and GOPs reported that their governors are operational.
- 80–85% (by interconnection) of the governors were reported to be capable of sustaining primary frequency response for longer than 1 minute if the frequency remained outside of their deadband.
- Roughly 50% of the governors reported that they had unit-level or plant-level control systems that override or limit governor performance.

Despite the fact that the majority of generators reported they have operational turbine governors, half of them have unit- or plant-level control systems that override governor responses. These control systems allow the units to return to scheduled output (MW setpoint) or an optimized operating point for economic reasons. These factors heavily influence the sustainability of primary frequency response, contributing to the withdrawal symptom often observed. This is often evident during light load periods in the middle of the night when high-efficiency, low-cost units that operate on MW setpoints are the majority of the generators dispatched to serve load.

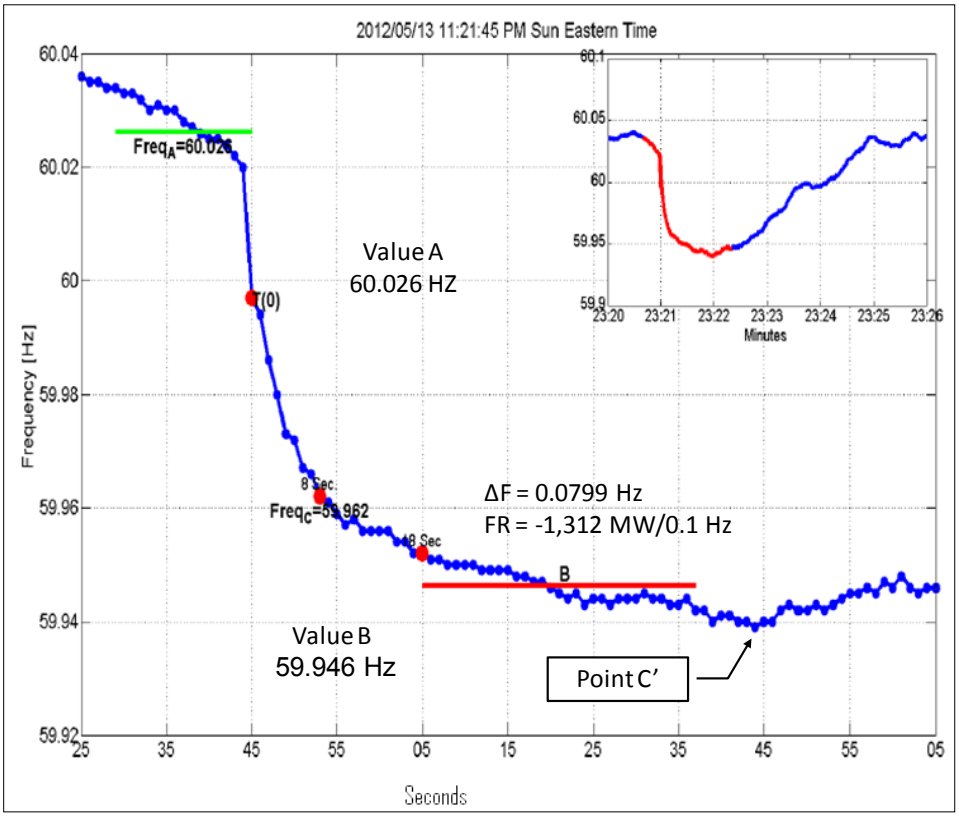
This was exhibited by two events involving generator trips in the spring of 2012 in one weekend. During the first event (figure 19), 1,711 MW of generation was tripped with a typical -2,369 MW/0.1 Hz frequency response.

Figure 19: 3:30 pm Saturday Afternoon 1,711 MW Resource Loss



The second event (figure 20) occurred late Sunday night when load in the Eastern Interconnection was much lighter, and the generators dispatched—probably the most efficient units—were of a different character. Despite the resource loss being almost 700 MW less, the frequency response of the interconnection was significantly reduced and exhibited the "lazy L" of primary frequency response withdrawal. Point C defined to occur during the first 8 seconds (at that time) was 59.962 Hz, while a lower point of about 59.939 Hz occurred about 1 minute after the event.

Figure 20: 11:21 pm Sunday Night 1,049 MW Resource Loss



These two events point to the composition of the dispatch and the characteristics of the units on-line as primary elements in the frequency response strength, as well as the key elements in creating withdrawal. Therefore, when calculating an Interconnection Frequency Response Obligation (IFRO), it is important for operational planners and operators to recognize the potential for that withdrawal and the frequency consequentially being lower one to two minutes after the beginning of the event.

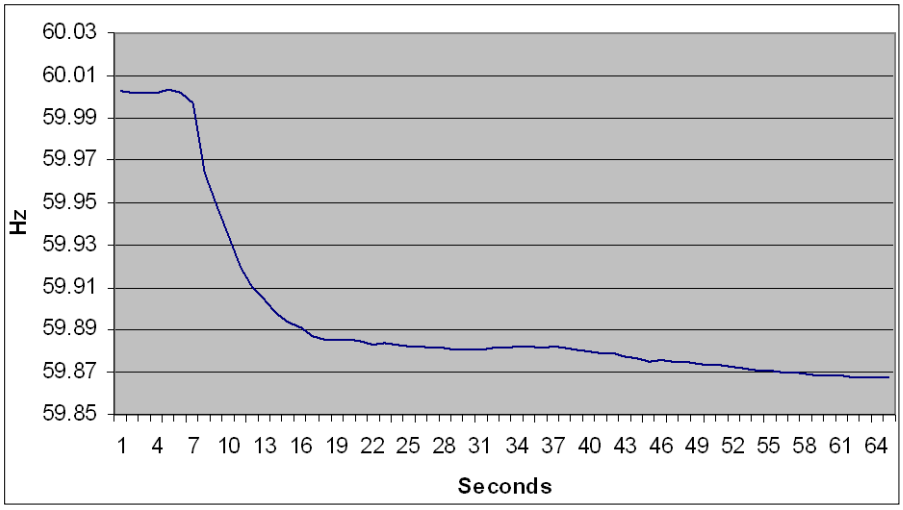
A similar withdrawal was experienced during the major frequency excursion of August 4, 2007 (figure 21). During that event some 4,500 MW of generation was lost.

The lowest frequency in the event was 59.868 Hz at about one minute after the start. Recovery to pre-event frequency was about 8 minutes, but the measurement of Value B (20 to 52 seconds) would not capture the lowest frequency. That frequency point is the true frequency

event nadir, hereafter referred to as Point C' ("Point C Prime"), and is normally equal to Point C for events that don't exhibit the so-called "lazy L" effect.

It is important that the phenomenon be recorded and trended to determine if it is improving or deteriorating.

Figure 21: Interconnection Frequency – August 4, 2007 EI Frequency Excursion



Recommendation – Measure and track frequency response sustainability trends by observing frequency between T+45 seconds and T+180 seconds. A pair of indices for gauging sustainability should be calculated comparing that value to both Point C and Value B.

Modeling of Frequency Response in the Eastern Interconnection

Modeling of frequency response characteristics has been a known problem since at least 2008, when forensic modeling of the Eastern Interconnection required a "de-tuning" of the existing MMWG dynamics governor to 20% of modeled (80% error) to approach the measured frequency response values from the event.

Figure 22 shows the response comparison for that event analysis. Although the event was an over-frequency problem at that point, it is indicative of the larger problem of governor modeling in the Eastern Interconnection. The problem was further highlighted in the 2010 "Use of Frequency Response Metrics to Assess the Planning and Operating Requirements for Reliable Integration of Variable Renewable Generation," by Ernest Orlando Lawrence Berkeley National Laboratory (LBNL). In that analysis, an attempt was made to simulate a 4,500 MW loss event that occurred on August 4, 2007. Figure 23 shows a comparison of the simulation to the measured frequency from the event.

Figure 22: 2007 Event Frequency Response Forensic Analysis

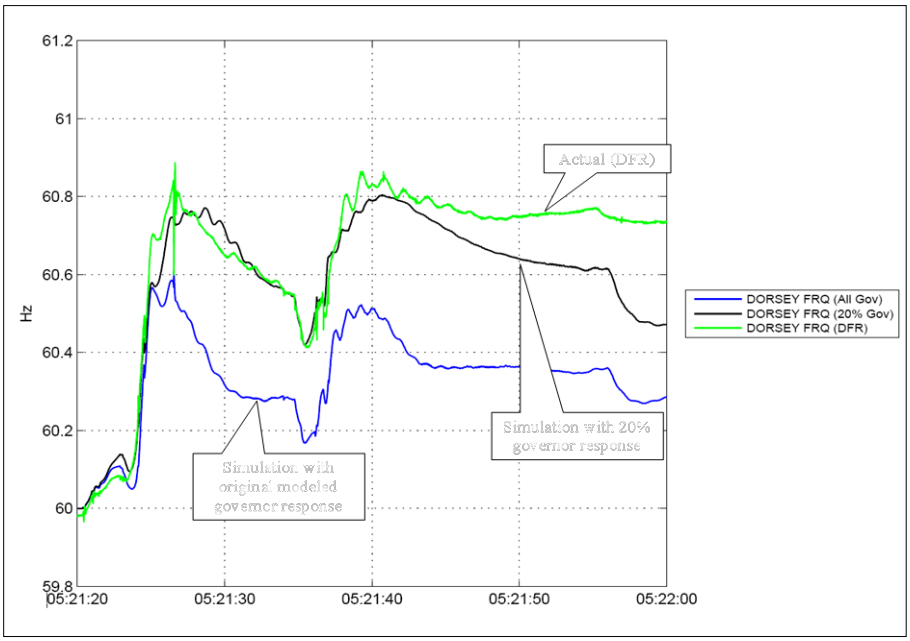


Figure 23: Eastern Interconnection Frequency Response – August 4, 2007 Initial 20 Seconds

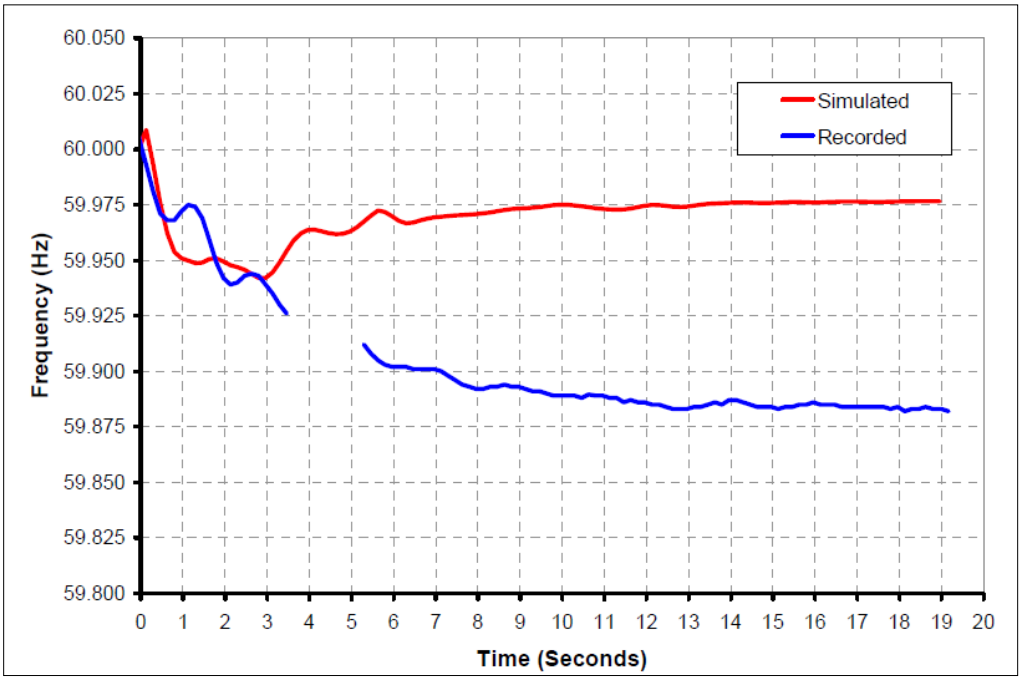


As part of the NERC Frequency Response Initiative and the Modeling Improvements Initiative, NERC collaborated with the Eastern Interconnection Reliability Assessment Group (ERAG) Multiregional Modeling Working Group (MMWG) to perform an analysis of the modeling of overall frequency response in the Eastern Interconnection. That review was a prelude to a plan

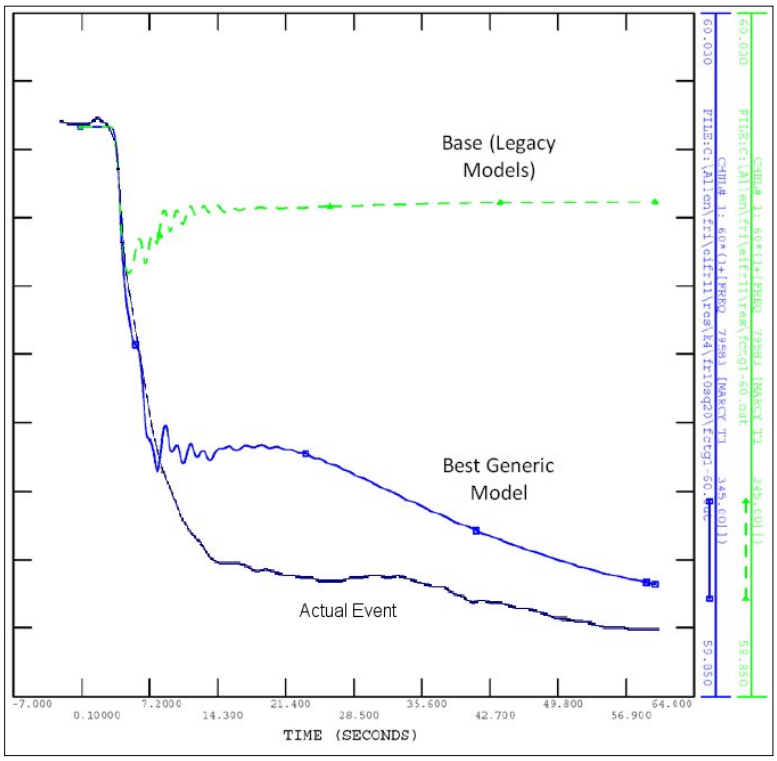
for thorough examination of the governor models in the Eastern Interconnection dynamics study cases that are assembled by the MMWG. That report stated, "The turbine-governor modeling currently reflected in the MMWG dynamics simulation database is not a valid representation of the frequency control behavior of the Eastern Interconnection."

That project created a "generic case" dynamics model, replacing the turbine governor models in the case with a generic governor model in order to ascertain the basic characteristics of the frequency response of the Eastern Interconnection. Figure 24 shows a comparison of the actual event data and the simulations using the original governor data and the generic case.

The characteristics found in that study were:

- Only 30% of the units on-line provide primary frequency response.
- Two-thirds of the units that did respond exhibit withdrawal of primary frequency response.
- Only 10% of units on-line sustain primary frequency response.

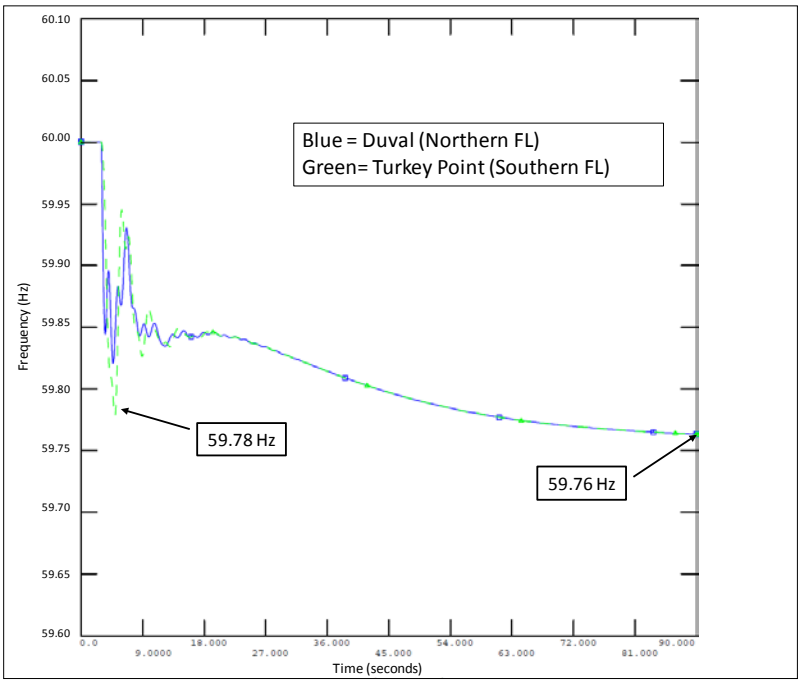
Figure 24: Comparison of Legacy and Generic Simulations to August 4 Event



Following that study, a follow-on analysis was performed by NERC staff to determine the general order of magnitude of a frequency event that could be sustained by the Eastern Interconnection without violating the 59.7 Hz first step UFLS in FRCC. A simulation was run that tripped about 8,500 MW of generation in the southeast United States (north of Florida). Figure 25 shows the result of that testing.

The simulation showed that the lowest frequency would be about 59.76 Hz in southern Florida. The initial nadir of 59.78 Hz in southern Florida is lower than the nadir in northern Florida due to the wave properties of the disturbance.

Figure 25: 8,500 MW Resource Loss Simulation



Although the simulations using the generic governor models are not exact, that analysis is indicative of the Eastern Interconnection's ability to sustain a resource loss event significantly higher than the Resource Contingency Protection Criteria proposed in this report.

Concerns for Future of Frequency Response

There is a growing concern about the future of frequency response in light of a number of factors:

- **Electronically coupled resources** – The incorporation of renewable resources such as wind and solar and the increasing penetration of variable speed motor drives presents a continuing erosion of system inertia; all are electronically coupled to the system. As such, those resources, unless specifically designed to mimic inertial response, do not have inertial response.

- **Electronically coupled loads** – As synchronous motors are replaced by variable speed drives, the load response of the motors is eliminated by the power electronics of the motor controller. This reduces the load damping factor for the interconnection.

- **Displacement of traditional turbine-generators in the dispatch** – Traditional turbine-generators are being displaced in the dispatch, particularly during off-peak hours when wind generation is at its highest and the loads and generation levels are at their lowest.

Such displacement of frequency responsive resources increasingly depletes the inertia of the interconnection at those times.

Role of Inertia in Frequency Response

Inertia plays a crucial role in determining the slope of a frequency decline during a resource loss event.

The slope of frequency excursion is determined by the inertia of the system and a factor to account for the load damping characteristics of the interconnection.

$$\frac{\quad}{\quad}$$

Where:

D = Load Damping Factor

The load damping factor ranges from 0 to 2, where 2 would represent a load of all motors.

H = Inertia Constant of the interconnection

The inertia constant ranges from 2.5 to 6.5

Figure 26 shows the sensitivity of frequency response to changes to system inertia. The lower green curve represents an inertia constant of 2.5, and the lower red curve represents an inertia constant of 5.0.

Figure 26: Frequency Response Sensitivity to System Inertia

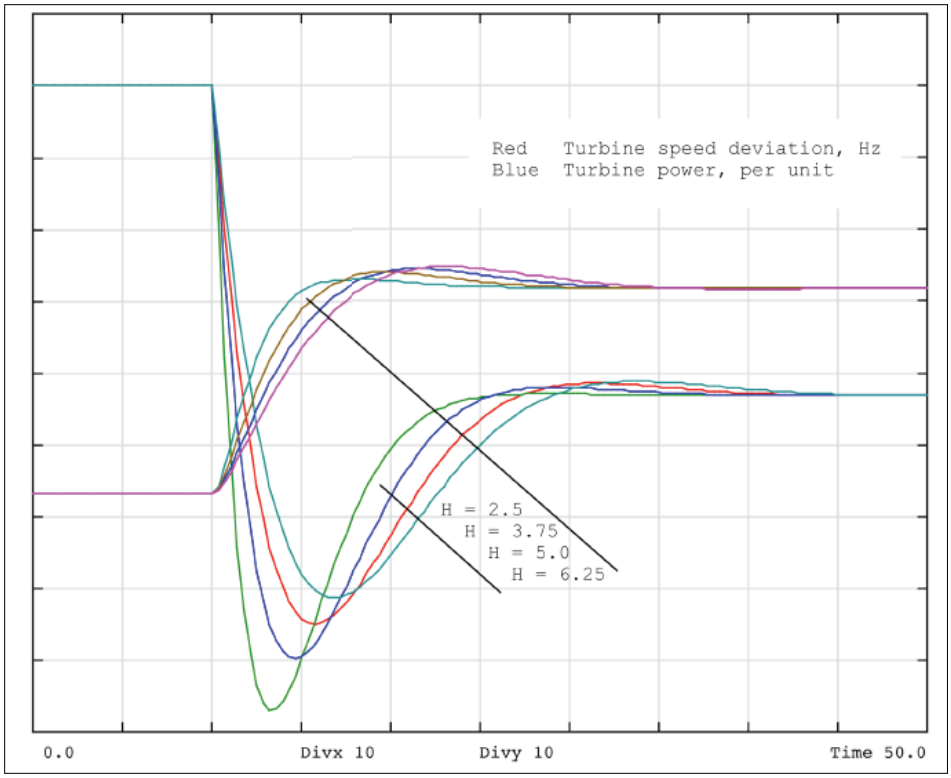


Figure 27 shows an actual example from ERCOT of how frequency response is changed for similarly sized resource loses with differences in inertia. It is clear that when the inertia on the system is lower, a similar resource MW loss creates a much steeper and deeper frequency excursion. This is a good example of the displacement of traditional resources with electronically coupled resources during light load periods.

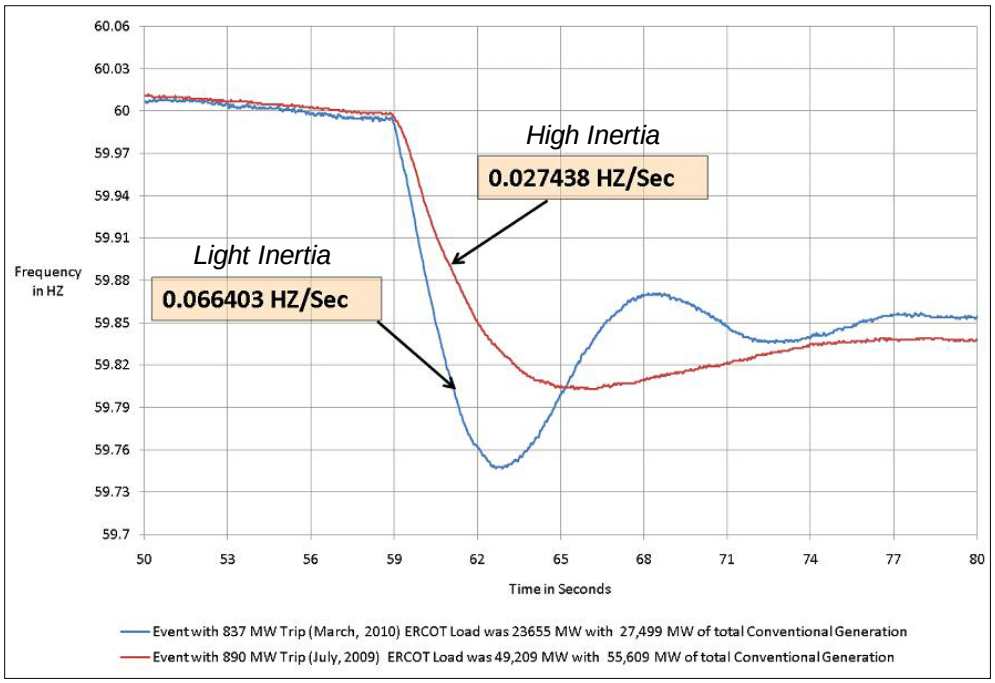
Figure 27: Inertial Response Sensitivity



Need for Higher Speed Primary Frequency Response

The reduction of inertia drives a need for higher speed response to frequency excursions. If the slope of the frequency decline is steeper, it is necessary for high-speed injection of energy to arrest the decline in order to prevent the excursion from being too deep. Such energy injection can come from a number of sources, such as energy storage devices and wind turbines with modified inverters.

Preservation or Improvement of Existing Generation Primary Frequency Response

Additionally, to further ensure strong overall frequency response, it is important to preserve or improve the primary frequency response of the existing generation fleet. The Role of Governors section of this report discusses the results of the 2010 survey on generator governors. The survey results show that there is a significant portion of the existing generator fleet that has operational governors. However, the reported deadband ranges make those governors ineffective for all but catastrophic losses of resources. Figure 28 shows the reported deadband ranges.

If the existing generator fleet primary frequency response performance can be improved through adjustments in deadbands and implementation of no-step droop responses, a significant improvement in interconnection frequency response could be realized. Further, if all of the existing generators were made capable of response, any generators that are on-line during light load periods would be more able to provide response.

Figure 28: Reported Governor Deadband Settings

The Role of Governors section of this report recommends immediate development of a NERC turbine-generator governor guideline calling for deadbands of ±16.67 mHz with droop settings of 4%–5% depending on turbine type in order to retain or regain frequency response capabilities of the existing generator fleet.

Withdrawal of Primary Frequency Response

Withdrawal of primary frequency response caused by outer-loop control systems must be addressed. As shown in the Frequency Response Withdrawal section of this report, frequency response during light load periods can be highly influenced by the mix of dispatched resources. Economics of the dispatch dictates that the most efficient, cost-effective generation will remain on-line during those periods. Such generation employs setpoint controls that return generation to AGC-prescribed or efficiency-prescribed generation levels regardless of system frequency. This results in "squelching" of any primary frequency response that the governors may have provided during a frequency event. This withdrawal of primary response before secondary frequency response from AGC becomes effective starting at about T+45 to T+60 seconds, creating the "lazy L" event response prevalent in the Eastern Interconnection.

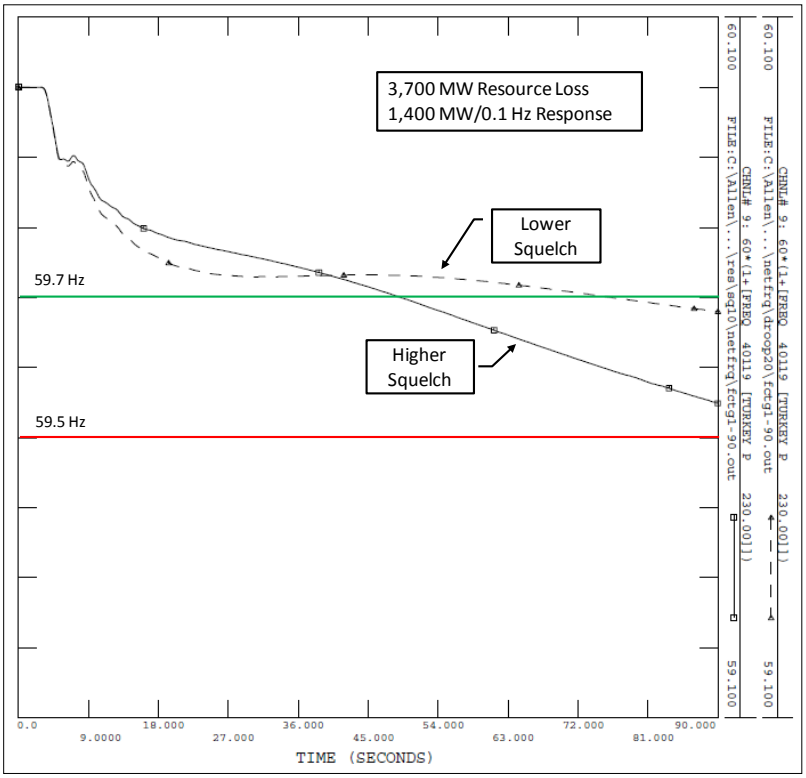
To illustrate this effect, a dynamic simulation of a 3,700 MW resource loss frequency event was performed for the Eastern Interconnection using the generic dynamics case described in the Modeling of Frequency Response in the Eastern Interconnection section of this report. Two simulation runs were performed to mimic about 1,400 MW/0.1 Hz frequency response

(between 20 and 52 seconds), with different combinations of generator dispatch and differing amounts of response "squelch." Figure 29 shows that the effects on frequency response sustainability can be highly influenced by the composition of the resource dispatch, even with the same measured frequency response.

There are potential ways of alleviating this withdrawal symptom, including introduction of a frequency bias into the outer-loop controls systems that would prevent withdrawal of primary frequency response, similar to the frequency bias settings in an automatic generation control (AGC) system.

Recommendation – NERC should include guidance on methods to reduce or eliminate the effects of primary frequency response withdrawal by outer-loop unit or plant control systems.

Figure 29: Simulations of Varying Levels of Primary Frequency Response Withdrawal Eastern Interconnection



Note that these simulation runs were done for illustrative purposes only; the simulations are not yet accurate enough to confidently predict system performance, and AGC secondary frequency response was NOT simulated. Secondary frequency response from AGC becomes effective starting at about T+45 to T+60 seconds.

Interconnection Frequency Response Obligation (IFRO)

Tenets of IFRO

The IFRO is intended to be the minimum amount of frequency response that must be maintained by an interconnection. Each Balancing Authority in the interconnection should be allocated a portion of the IFRO that represents its minimum responsibility. In order to be sustainable, Balancing Authorities that may be susceptible to islanding may need to carry additional frequency responsive reserves to coordinate with their under-frequency load shedding (UFLS) plans for islanded operation.

A number of methods to assign the frequency response targets for each interconnection can be considered. Initially, the following tenets should be applied:

1. A frequency event should not trip the first stage of regionally approved UFLS systems within the interconnection.
2. Local tripping of first-stage UFLS systems for severe frequency excursions, particularly those associated with protracted faults or on systems on the edge of an interconnection, may be unavoidable.
3. Other frequency-sensitive loads or electronically coupled resources may trip during such frequency events (as is the case for photovoltaic inverters in the Western Interconnection).
4. Other susceptible frequency sensitivities may have to be considered in the future (e.g., electronically coupled load common-mode sensitivities).

UFLS is intended to be a safety net to prevent against system collapse from severe contingencies. Conceptually, that safety net should not be violated for frequency events that happen on a relatively regular basis. As such, the resource criteria are selected to avoid violating UFLS settings approved by the Regional Entities.

The Frequency Responsive Reserve Standard Drafting Team (FRRSDT) is proposing an administered value approach for the BAL-003-1 field trial. Eventually, an agreed-upon method of determining the interconnection FRO will be included in a reliability standard, or in the NERC Rules of Procedure.[31]

[31] http://www.nerc.com/files/NERC_Rules_of_Procedure_EFFECTIVE_20110412.pdf

Statistical Analyses

Frequency Variation Statistical Analysis

A statistical analysis of the variability of frequency for each of the four interconnections was performed using 1-second measured frequency for the Eastern, Western, and ERCOT Interconnections for 2007–2011 (five years). Data for the Québec Interconnection was only available for 2010 and 2011. Analysis of data showed the Western Interconnection frequency deviations (Epsilon) to be more volatile since the Balancing Authority ACE Limit (BAAL) field trial began there in March of 2010. Therefore, it was decided to limit the analysis to the years 2009–2011 to more accurately portray the current frequency characteristics.

This variability accounts for items such as time error correction; variability of load, interchange, and frequency over the course of a normal day; and other uncertainties, including time error corrections and all frequency events—no large events were excluded. The results of the analysis are shown in table 3.

Table 3: Interconnection Frequency Variation Analysis (Hz)

Value	Eastern	Western	ERCOT	Québec
Timeframe	2009–2011	2009–2011	2009–2011	2010–2011
Number[32] of Samples	91,283,555	90,446,802	85,924,929	34,494,049
Expected Value	60.0000367	59.9999522	59.9999847	60.00002303
Maximum Value	60.3090	60.3575	62.1669	60.8776
Minimum Value	59.0015	59.7364	58.0000	59.1879
Variance of Frequency (σ^2)	0.00024092 Hz^2	0.00022266 Hz^2	0.00060749 Hz^2	0.00035315 Hz^2
σ	0.01552147	0.01492184	0.02464722	0.01879236
2σ	0.03104295	0.02984369	0.04929445	0.03758472
3σ	0.04656442	0.04476553	0.07394167	0.05637708
Starting Frequency (F_{Start}) 5% of lower tail samples	59.974	59.976	59.963	59.972

[32] Numbers of samples vary due to exclusion of data drop-outs and other obvious observation anomalies.
