				<p>Transmission Planner or Planning Coordinator functions.</p> <p>2. R2.7.2 - "include actions to resolve performance deficiencies identified in multiple sensitivity studies" - Mitigation plans should not be required for deficiencies found in multiple sensitivity studies because the conditions in some sensitivity studies are more extreme and less likely than base case conditions. Some of the sensitivity study conditions are not credible or plausible enough to warrant the implementation of mitigation measures. It is not clear if the interpretation of multiple studies is more than one or a majority of the number that were studied.</p> <p>3. Throughout the Standard there are circular references that make the interpretation confusing. We recommend that all references should refer back to previous sections and not to future sections, thereby avoiding circular references.</p> <p>4. We disagree with the proposed definition of Year One. Year One should be the planning window that begins 12-18 months from the start of the calendar year, and not from the end of the calendar year. This would require minimal adjustments to the ERAG MMWG model building process. The proposed definition would force additional models to be built by the MMWG.</p> <p>5. We agree with others that the timeframe of 60-month (5 year) for implementing Corrective Action Plans (CAP), is insufficient. We believe that the implementation timeframe must be extended to seven (7) years. GTC is aware of Requirement 2.7.3, which covers situations that arise beyond the control of the Transmission Planner (TP) or Planning Coordinator (PC), but believes that the proposed language is ambiguous.</p> <p>6. We have concerns for including induction motor representations in the load models without any study or bench-marking activities to meet the requirements of R2.4.1. This information should be supplied by the LSE as part of the MOD standard. We understand that the proposed standard will accept an aggregate system load model which represents the overall dynamic behavior of the load to relieve the burden of trying to develop specific induction motor load representation at each load bus. However this modeled system response will be considerably different compared to the actual system response which will open up the industry to unwarranted scrutiny and possible compliance violation investigations.</p> <p>7. We disagree with the inclusion of low voltage ride-through in requirement R3.3.2. Low voltage ride-through is a dynamic modeling issue as correctly included in requirement R4.3.2.</p> <p>8. "EHV" and "HV" need to be defined in the NERC Glossary.</p> <p>9. Requirement R2.4.2 needs to be better defined. It is not clear if this requirement is meant to demonstrate acceptable system performance during maintenance outages over the daily peak load</p>

Voter	Entity	Segment	Vote	Comment
				<p>periods of the off-peak season or intended to address light-load issues like over-voltages and frequency deviations.</p> <p>10. A better definition for Consequential Load Loss is needed. The Non-Consequential Load Loss definition conflicts with the Consequential Load Loss definition. The Response of Voltage Sensitive Load exception under the Non-Consequential Load definition is a circular reference. It is not clear whether Voltage Sensitive Load is Consequential Load Loss or Non-Consequential Load Loss.</p> <p>11. It is not clear if Consequential Load Loss is intended to be limited to: a) Load between two open (breaker/switches) protective devices and b) Protective devices (breakers/switches) for radial load.</p> <p>12. Requirement R1.1.5 states that the system model shall represent "Known commitments for Firm Transmission Service and Interchange". GTC requests clarification of how to represent "Known commitments" whose collective magnitude can exceed the Load requirements.</p>

Response: 1. If an entity can demonstrate that it has made a best faith effort to implement the planned solution then there should not be a concern. The wording of the requirement allows an entity this flexibility.

2. Requirement R2, part 2.7.2 already states that an entity must supply the rationale for when actions were not necessary so the SDT believes that your concerns have already been addressed. No change made.

3. The SDT has made every attempt to make the standard as easy to follow as possible and believes that all references cited in the standard are correct. No change made.

4. Based on your comment and those of others, the SDT has revised the definition of Year One.

Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For the Planning Assessment started in a given calendar year, Year One must include the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013.

5. The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order. Requirement R2, part 2.7.3 - If an entity can demonstrate that they have made a best faith effort to implement the planned solution then there should not be a concern. The wording of the requirement allows an entity this flexibility.

6. The SDT does not disagree that the Load Serving Entity may provide the initial information but someone needs to be responsible for adapting the model accordingly and that entity has to be the Transmission Planner or Planning Coordinator. No change made.

7. The SDT voltage ride through is not confined to the dynamic period. There are protection requirements that could result in generator tripping and that must be

Voter	Entity	Segment	Vote	Comment
<p>considered in the steady-state analysis. The SDT has clarified the wording of the requirement.</p> <p>Requirement R3, part 3.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:</p> <ul style="list-style-type: none"> • Tripping of generators where simulations show generator bus voltages or high side of the Generation Step Up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made. • Tripping of Transmission elements where relay loadability limits are exceeded. <p>8. The EHV/HV differentiation is not meant to be a definition in that it only applies to this standard. No change made.</p> <p>9. The requirement was intended to cover all conditions that could occur during Off-Peak periods. No change made.</p> <p>10. The definitions are not in conflict as the definition of Non-Consequential Load Loss specifically states that it doesn't include Consequential Load Loss. The response of Load to voltage is not classified as Consequential or Non-Consequential Load Loss. This standard articulates how voltage sensitive Load should be treated during different time periods of a simulation. No change made.</p> <p>11. Both examples provided are Consequential Load Loss per the definition.</p> <p>12. The SDT does not believe that a continent-wide standard should proscribe a single approach. Requirement R1 states that an entity must document its assumptions. No change made.</p>				
Gordon Pietsch	Great River Energy	1	Negative	<p>GRE recommends the following revision to the wording in subrequirement 2.5: "...the impact of proposed generation additions that have made a commitment to interconnect with the Bulk Electric System..."</p> <p>In addition, it appears that the drafting team has inadvertently included additional compliance requirements in the language of Table 1. The net result of this is that these requirements are effectively buried in the Table 1 language. GRE does not take exception to these additional requirements but believes that they should be included in the Requirements section of the Standard. Having the Table 1 language written as it is presents additional risks for non-compliance that would not otherwise be there if these requirements would be included in the Requirements section.</p>
<p>Response: The SDT has clarified this requirement based on industry comments.</p> <p>Requirement R2, part 2.5 - The Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, part 2.6. The technical rationale for determining material changes shall be documented.</p>

Without any specific comments to address, the SDT is unable to further address your concerns. No change made.				
Jacquie Smith	ReliabilityFirst Corporation	10	Negative	<p>In R1.1.6 is OR the proper description of resources? Shouldn't this be AND? Resources are both supply AND demand side.</p> <p>Is R4.1.2 too stringent. At the least, shouldn't there be an exception for Special Protection Systems and Remedial Action Schemes to trip for apparent impedance swings?</p> <p>In 4.3.1 shouldn't the analysis be for both successful high speed reclosing and for unsuccessful high speed reclosing, (AND instead of OR)</p> <p>In Measure 8, the mixture of OR and AND is confusing. As presently written, as long as no entity makes a written request for the information they pass the test. Thus, as long as your neighbors do not complain about not receiving the information an entity is compliant. Better wording would be: The responsible entity failed to distribute the results of its Planning Assessment to one of its adjacent Transmission Planners, or one of its adjacent Planning Coordinators, or to one functional entity The responsible entity failed to distribute the results of its Planning Assessment to two or more of its adjacent Transmission Planners, adjacent Planning Coordinators, functional entity Also, I think failure to distribute results is more severe than failing to respond to comments. Failing to give their neighbors an opportunity to comment is less severe than failing to acknowledge comments. I presume that the documented response to comments can be nothing more than "Thank you for your comments."</p> <p>All of the above are minor compared to this next problem. (I believe this needs to be addressed before we can vote yes.) The level of detail of Planning Assessment results is missing from the requirements. Is a message to your neighbors stating that you have performed a Planning Assessment and everything is OK, enough to meet the requirement, or does it need to be more detailed? The minimum contents of the Planning Assessment results shared with Transmission Planners, Planning Authorities, and other functional entities needs to be clearly stated.</p> <p>Also, the RRO is not a functional entity. As written, can this standard be used as justification for not sending detailed Reliability Assessment information to the ReliabilityFirst? Would requiring sharing with Stakeholders with a reliability need be better than limiting the required sharing to functional entities?</p>
<p>Response: The SDT believes that 'or' is appropriate. This allows for an entity to model supply or demand or both as appropriate. No change made.</p> <p>Requirement R4, part 4.1.2, deals with a single generator pulling out of synchronism. The situation you described is a system Stability issue and is considered an</p>

Kathleen Goodman	ISO New England, Inc.	2	Negative	<p>ISO New England is submitting a negative vote on the TPL-001 standard, because:</p> <ol style="list-style-type: none"> 1. Section 2 of the standard requires annual assessment of the system regardless of whether system conditions are essentially unchanged from year to year. This creates unnecessary study work and must be changed in order for ISO NE to support the standard. 2. In Table 1 - Steady State & Stability Performance Planning Events, Category P5 wording for the EHV contingency continues to call for no loss of load in the event of the loss of a single protection system. This requirement as currently worded goes well beyond the intent of the Standard Committee as stated in response to comments as follows: "A Protection System component failure (i.e., battery) that removes multiple Protection System schemes is beyond the P5 planning event". It is ISO New England's opinion that similar language to the comment response should be incorporated into this requirement. 3. ISO New England has additional reservations about the standard that should be addressed in subsequent revisions however items 1 and 2 here must be addressed for ISO New England to support the standard.
<p>Response: 1. The intent of the SDT wasn't that annual studies are required but that an annual Planning Assessment is required. However, the SDT agrees that the words may have been somewhat confusing. Therefore, the SDT has clarified the wording of Requirement R2 and part 2.1.</p> <p>Requirement R2 - Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.</p> <p>Requirement R2, part 2.1 - The Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, part 2.6, as follows:</p> <ol style="list-style-type: none"> 2. The SDT has changed the text for the P5 event as a result of your (and others) comments to address these concerns. <ul style="list-style-type: none"> P5. Delayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed, for a Fault on one of the following: <ul style="list-style-type: none"> 13. Brian Conroy	Central Maine Power Company	1	Negative	<p>Issues with TPL-001-1 draft 5 in ballot:</p> <p>R 1 & 2 - There is insufficient direction/specification regarding base case development and sensitivity testing. Only "known outage(s) of generation" is specified.</p> <p>R2.1.1 - Year One or year two are operating time frame studies. Year five, particularly with additional load from load growth, is appropriate for system planning. There should not be a requirement for any more than one short-term and one long-term steady-state assessment.</p> <p>2.1.5 - The 'spare equipment strategy' requirement effectively amounts to a N-1-1 analysis, but without the system adjustment between contingencies. A N-1-1 analysis should be sufficient.</p> <p>R2 - An annual assessment of the system is required regardless of whether system conditions are essentially unchanged from year to year.</p> <p>Note that R2.6 is only for 'support' and are 'supplementation.' This creates unnecessary study work and must be changed in order for ISO NE to support the standard.</p> <p>R2.4.1 - The dynamic load model must consider the behavior of induction motor Loads in the stability assessment. The behavior of customers' induction motor loads is not known.</p> <p>Table 1, Category P5, EHV - loss of load in the event of a fault plus the loss of a protection system, should be allowed.</p> <p>This requirement as currently worded goes well beyond the intent of the Standard Committee as stated in response to comments as follows: "A Protection System component failure (i.e., battery) that removes multiple Protection System schemes is beyond the P5 planning event". The draft standard is too prescriptive in some areas and too open to various interpretations in others.</p>

Response: System normal, or P0, is the starting system condition for the projected study conditions per the model developed in accordance with Requirement R1. Requirement R1 contains more than just 'known outages of generation' that need to be considered. The SDT has adjusted Requirement R1 to provide this clarity. The SDT believes that sufficient direction on sensitivities is in the requirement but the SDT has made a slight clarifying change to the requirement.

Requirement R1 - Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes the normal system condition in Table 1.

The SDT has changed the definition of Year One to more clearly show the SDT's intent. The SDT believes that two near-term studies are necessary in order to calibrate the planning assumptions against operations (Year One or year two) and to provide an additional data point for interpolation (Year One or year two and

Voter	Entity	Segment	Vote	Comment
				<p>year five).</p> <p>Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. Voter	Entity	Segment	Vote	Comment
Lorees Tadros	Omaha Public Power District	1	Negative	<p>It's unclear what the intent of the SDT was in Requirement R6, especially when R6 is considered in conjunction with Measurement M6. R6 includes the phrase "for conditions such as Cascading, voltage instability, or uncontrolled islanding", while M6 does not. R6 and M6 should use parallel language, similar to the way R5 and M5 use parallel language.</p> <p>Additionally, why is "System instability" mentioned in R6 for conditions such as Cascading, voltage instability, or uncontrolled islanding, when in Note "a" at the top of Table 1, the requirement that Cascading, voltage instability, and uncontrolled islanding not occur applies to both steady-state and stability analysis?</p> <p>In Note "f" at the top of Table 1, the word "applicable" was inserted in front of the term "Facility Ratings". The word "applicable" is unnecessary and should be struck. Inclusion of it could lead to certain Planning Coordinators and Transmission Planners interpreting it in ways that were never intended by the SDT.</p> <p>The word "applicable" should also be struck from Footnote 9 of Table 1.</p> <p>A reference to Footnote 9 was added to each occurrence of the word "No" in the second-to-last column of Table 1. This is confusing, because a "No" in this column means that interruption of firm transmission service is not allowed, while Footnote 9 says that curtailment of firm transmission service is allowed. This needs to be clarified.</p>

Response: The SDT agrees and has revised the wording accordingly.

M6. Each Transmission Planner and Planning Coordinator shall provide evidence, such as electronic or hard copies of documentation specifying any criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

Requirement R6 is documentation for criteria and methodology for risk exposure to those items. The SDT does not believe it is in conflict with header note 'a'. This is parallel to using thermal ratings to determine if lines become overloaded during the analysis. No change made.

The word 'applicable' is correct as ratings vary over time and the standard must accommodate this situation. No change made.

As a general rule, curtailment is not allowed. The footnote sets out exceptions to that as long as the conditions in the footnote are met. The SDT believes that this is the proper method to present the concept. No change made.

Voter	Entity	Segment	Vote	Comment
Garry Baker	JEA	3	Negative	JEA is concerned that there are some limited prudent cases where consumers, local jurisdictions, and state jurisdictions may find it prudent to plan on some Non-Consequential Load Loss in order to defer building transmission infrastructure for the overall benefit of the consumer. Therefore, JEA proposes the addition to the standard that allows the use of Non-Consequential Load Loss for local area planning.
Brad Chase	Orlando Utilities Commission	1	Negative	OUC appreciates that hard work of the STD and of the industry in reviewing and commenting on these standards. The STD has worked hard to try to address the concerns of the industry. OUC is voting against these standards. The proposed standard raise the bar in terms of study and performance requirements, an increase that will result in a non trivial increase in costs for utilities to meet the standards. The change in the standard did address some ambiguities in the old standard, but also introduced some new ones. Reviewing the new standard against the old OUC finds that our cost and that of our neighbors will increase to meet these standards. However OUC does not believe there will be a real increase in reliability on either the bulk system or at the individual user level due to these increased costs. In the current environment the direction from our customers is to keep rates as low as possible, and from our regulatory agency it is to have as little environmental impact as possible. The customers and regulatory agency do look at outages, but transmission is very rarely a contributor to those outages and funds expended can be better spent elsewhere, like on the distribution system or hurricane hardening, then on studying and constructing redundant transmission facilities that provide little to no increase in the end user's reliability. The standard also reduces the range of circumstances where non-consequential load loss is acceptable. OUC does not generally rely on consequential load loss for these circumstances, but this is a choice made based on feedback from our customers and local regulatory authorities. Consequential load loss, when confined to a limited area, is not a Bulk Electric System reliability issue. It is an issue best addressed locally where the cost in terms of capital facilities, condemnation, environmental impacts, probability of event and severity of event can be evaluated and a decision made that addresses these issues. A miniscule decrease in the risk of an outage would often be desirable to the community due to the subsequent rate increase and the impact of constructing power lines through their wetlands, scenic and urban areas. Since such an outage is not even noticeable at a regional scale, the choice should be left to those impacted, not mandated by NERC.
Richard Kinas	Orlando Utilities Commission	5	Negative	
Ballard Keith Mutters	Orlando Utilities Commission	3	Negative	
Kimberly J. Jones	North Carolina Utilities Commission	9	Negative	The NC Utilities Commission is concerned that the requirement prohibiting loss of non-consequential load for events in Table 1 of TPL-001-1 is an inappropriate overreach into service issues that are more appropriately addressed by state regulatory commissions. This requirement does not provide any benefit to reliability of the bulk electric system and could undermine state efforts to balance

Voter	Entity	Segment	Vote	Comment
				reliability issues with cost of service issues. Requiring remediation by a date certain could frustrate the coordinated siting of new lines with other planned infrastructure upgrades such as highways or bridges. The standard should continue to allow Transmission Planners to use discretion regarding loss of non-consequential load, understanding that state commissions are positioned to force electric utilities to address service quality issues on an expedited basis, should it be necessary and in the public interest.
<p>Response: The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p>				
Mike Laney	Luminant Generation Company LLC	5	Negative	<p>Luminant supports the concept of a more robust transmission planning criteria as described in TPL-001-1, but has serious concerns about the timeline being proposed. The 60-month implementation timeframe associated with the elimination of non-consequential load loss does not have any mechanisms to respect the base level of construction activity already underway in the various NERC regions that may materially impact compliance with a 60-month timeline. In ERCOT, the Public Utility Commission of Texas (PUCT) has mandated the construction of over 4,400 circuit miles of transmission within the next five years to support over 18,000 MW of wind generation. The PUCT Competitive Renewable Energy Zones (CREZs) build out plan requires the ERCOT 345 kV transmission network to be expanded by ~51% (in terms of total circuit miles), necessitating complex coordination of transmission clearances for construction of new lines, making it difficult to economically operate in a secure manner. These new CREZ transmission facilities are scheduled for completion by 2014 (i.e., within the next 5 years). The concurrent implementation of TPL-001-01 will compete with the CREZ build-outs and other on-going transmission upgrades needed to support load growth in the ERCOT region, which has historically experienced higher load growth rates than other parts of the country. Given that these major activities (including CREZ) reflect the most aggressive transmission build out plan in the history of ERCOT and that the implementation of TPL-001-1 will only add to that, Luminant is concerned that adding the implementation of TPL-001-1 on top of these activities will not provide adequate clearance windows to economically or reliably implement this plan within the proposed 60-month implementation window. In light of these concerns, Luminant proposes a 120 month implementation timeline of TPL001-1 for the ERCOT region</p> <p>Additionally, Luminant would like to see safeguards added to TPL-001-1 that acknowledge that each NERC region must complete all of the identified transmission upgrades associated with implementation of TPL-001-1 before NERC regions are required to begin operating with this level of security constraints enforced. Given that it is not possible to operate a NERC region any more securely than it is planned to be operated, this type of safeguard may readily appear, but explicitly</p>

Voter	Entity	Segment	Vote	Comment
				stating it would still be helpful. With the modifications outlined above, Luminant could support TPL-001-1. Thanks for the opportunity to comment.
<p>Response: The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p> <p>The SDT has extended the implementation plan as described above and that Requirement R2, part 2.7.3 provides sufficient latitude for entities to accommodate your concern. No change made.</p>				
Terry Harbour	MidAmerican Energy Co.	1	Negative	MidAmerican find P5 confusing. What analysis is required? Does P5 specify the analysis of individual components of a System Protection system, the entire protection system as a whole, or something else? Do the benefits justify the requirement?
<p>Response: The SDT has changed the text for the P5 event as a result of your (and others) comments to address these concerns.</p> <p>P5. Delayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed, for a Fault on one of the following:</p> <p>13. Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).</p>				
John Canavan	NorthWestern Energy	1	Negative	<p>NorthWestern Energy Rationale for our Vote NO: Below are NorthWestern's Comments on TPL-001-1 Draft 5: January 6, 2010: While this document has improved slightly with each successive draft, there are still several flaws that persist that NorthWestern finds to be unacceptable:</p> <ol style="list-style-type: none"> 1. The definition of a Bus-tie Breaker is vague. As a practical matter any breaker could qualify. 2. The definition of Non-Consequential Load Loss doesn't fit its name. 3. The idea of a Planning Assessment (developed throughout the document) is loose enough that it seems always to be asking the Transmission Planner to "do another comprehensive study anyway just to be sure you won't get sanctioned". There were numerous discussions about this, but the Drafting team has not cleaned up the language on this. The original idea was that a TP whose comprehensive study was not rendered unusable by the developments of a single year could perform an Assessment, and reasonably re-use the results of that study for the following year. The language in R2.1 contains the language: "The Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following current studies, supplemented with qualified past studies as indicated in Requirement R2, part 2.6:" This language

Voter	Entity	Segment	Vote	Comment
				<p>convincing any Transmission Planning person that an annual analytical study complete with power flow simulations is required. This requirement is onerous, since there is a significant waste of manpower and resources involved in conducting such a study when for most years a bi-annual study program would clearly be sufficient. NorthWestern considers that this one issue is worthy of a NO vote based on the excessive nature of the requirement.</p> <p>4. The language in R2.3 requires a short circuit analysis to be conducted annually. As with our comment 3 above, we find this excessive. This level of vigilance is not commensurate with the potential threat of a situation where fault duty could exceed breaker interrupting capability.</p> <p>5. The stricter requirements in the table for EHV lines certainly "raise the bar" for these facilities. They are also likely to reduce the enthusiasm for building such facilities. The outcome of this may be unintended consequences that are far more onerous to society than the amount of load loss that is avoided by the standard. It is not clear that this addition to the standard is well reasoned.</p> <p>6. NorthWestern is concerned about the potential for uneven treatment by various auditors as they follow this standard. While there is some risk of this for any standard, we believe the language in this standard is still weak.</p> <p>7. The 60 month time limit for implementing Corrective Action Plans may be quite unrealistic in the Montana transmission line environment. It really is not clear what is in the Transmission Planner's "control" in this arena.</p> <p>8. The definition of "year one" is problematic. Presently the WECC does not produce base cases that are well suited to this choice.</p> <p>We would like to encourage the Drafting Team to work to "tighten up" the language in the standard. This particular standard is so important to the general reliability of the transmission system (BES) that it deserves an extra effort at clarity, conciseness, and thoughtful language to achieve truly beneficial practices in the design of the BES. We believe that a "NO" vote is our best recourse to promote this extra effort. We understand that this standard has been a "long time in the making". That is because it is truly a difficult drafting challenge, not because of a poor effort.</p>
<p>Response: 1. The definition has been iterated several times based on industry comments in the past and seems to have been accepted by the overwhelming majority of the industry to date. No change made.</p> <p>2. The use of non-consequential is in line with the previously used term 'consequential' and doesn't imply that it isn't important. No change made.</p> <p>3. The intent of the SDT wasn't that annual studies are required but that an annual Planning Assessment is required. However, the SDT agrees that the words may have been somewhat confusing. Therefore, the SDT has clarified the wording of Requirement R2 and part 2.1.</p>				

Voter	Entity	Segment	Vote	Comment
<p>Requirement R2 - Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.</p> <p>Requirement R2, part 2.1 - The Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, part 2.6, as follows:</p> <p>4. Past studies are allowed as long as they qualify as per Requirement R2, part 2.6 and that should alleviate your concern. No change made.</p> <p>5. There are many other factors over and above this standard that will determine what entities build in the future. The SDT and many stakeholders believe that it is important to raise the bar for reliability. No change made.</p> <p>6. The SDT has made every attempt to make this standard clear, unambiguous, and enforceable. Without any specific comments to address, the SDT is unable to further address your concerns. No change made.</p> <p>7. The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p> <p>8. Based on your comment and those of others, the SDT has revised the definition of Year One.</p> <p>Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For the Planning Assessment started in a given calendar year, Year One must include the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013.</p>				
David H. Boguslawski	Northeast Utilities	1	Negative	<p>NU votes to oppose TPL-001-1 with the following comments: Northeast Utilities (NU) is very appreciative of the effort of the SDT in preparing TPL-001-1. NU believes that this effort has resulted in a new TPL standard that shows improvement over the existing TPL standards. However, there are still some important concerns that NU believes should be addressed prior to the adoption of TPL-001-1. Therefore, in its present state NU can not vote for the acceptance of the draft standard and votes to REJECT the proposed standard (TPL-001-1). NU would like the SDT to re-visit and address the concerns listed below:</p> <p>1. The use of Non-Consequential Load Loss to mitigate violations arising from certain planning events: NU has objected to this requirement in comments submitted for previous drafts of TPL-001-1. NU believes that Non-Consequential Load Loss should not be considered for P1 to P7 events to achieve the level of reliability needed when planning the electric power system. The amount of load that could be shed is open ended in TPL-001-1 and this will lead to different interpretations which can be detrimental to the stakeholders. To put it simply the standard as currently drafted will lead to</p>

Voter	Entity	Segment	Vote	Comment
				<p>confusion as Transmission Owners, Regional Reliability Organizations, along with state and federal agencies will need to come to agreement on what the standard allows and what it doesn't. Ultimately, a standard that does not have clear measurable criteria will lead to difficulty in developing and obtaining approval for projects to achieve the required level of reliability. If the SDT and NERC believe that allowing the use of Non-Consequential Load Loss for multiple element contingencies (e.g., N-1-1 or P6 planning events) is necessary in achieving system reliability then NERC should specify that the amount should be minimal, such as less than 100 MW.</p> <p>2. The use of past study reports to satisfy Requirement R2, parts R2.1 and R2.2: The language of Requirement R2, parts R2.1, R2.2 and R2.6 is confusing and will lead to different interpretations from different stakeholders. While Requirements R2.1 and R2.2 indicate that annual studies should be conducted and to be supplemented by past studies, Requirement R2.6 seems to suggest that past studies could be used instead. The SDT's response to NU's comment on this issue supports the assertion that annual studies should always be conducted even if there are no changes in the system conditions and past studies should be used for the years within the assessment period but not called out by the standard. If studies are conducted every year then why the need to use past studies. This creates unnecessary study work and should be changed.</p> <p>3. Table 1 - Steady State & Stability Performance Planning Events, Category P5 Events: This requirement as currently worded goes well beyond the intent of the Standard Committee as stated in response to comments as follows: "A Protection System component failure (i.e., battery) that removes multiple Protection System schemes is beyond the P5 planning event". It is NU's opinion that similar language to the comment response should be incorporated into this requirement to avoid any confusion.</p> <p>4. Base case initial conditions: NU believes that a great deal of confusion and uncertainty will be eliminated or reduced if the standard attempts to define the nature of initial base cases that should be used in planning studies. As it stands now this issue is left to interpretation, which can lead to confusion when determining appropriate planning projects to achieve a reliable power system. Depending upon the interpretation of the base case dispatches and the level of interface flows (level of stress) they may reveal reliability violations in the power system. Non-uniformity in developing base cases for an area or region may mask real reliability problems in the system. This is one of the primary weaknesses of the existing TPL standards.</p> <p>5. Items 1, 2, 3 and 4 are Northeast Utilities primary concerns which should be addressed prior to NU accepting the standard. NU has additional reservations about the standard that should be addressed in subsequent revisions.</p> <p>6. NU also supports the comments from other transmission owners that 60 months may not be</p>

Voter	Entity	Segment	Vote	Comment
				sufficient to complete construction of transmission facilities.
<p>Response: 1. The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others' concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>2. The intent of the SDT wasn't that annual studies are required but that an annual Planning Assessment is required. However, the SDT agrees that the words may have been somewhat confusing. Therefore, the SDT has clarified the wording of Requirement R2 and part 2.1.</p> <p>Requirement R2 - Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.</p> <p>Requirement R2, part 2.1 - The Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, part 2.6, as follows:</p> <p>3. The SDT has changed the text for the P5 event as a result of your (and others') comments to address these concerns.</p> <p>P5. Delayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed, for a Fault on one of the following:</p> <p>13. Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).</p> <p>4. The SDT is trying to provide guidance without being overly prescriptive. Projected System conditions as well as the types of sensitivities that need to be studied are described. No change made.</p> <p>5. Without any specific comments to address, the SDT is unable to further address your concerns. No change made.</p> <p>6. The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. ince problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p>				
Henry G. Masti	New York State Electric & Gas Corp.	1	Negative	<p>NYSEG supports the NYISO comments and also offer: The standard requires that dynamic load models be used that take into account induction motor effects. This information is generally not available and therefore it would be unworkable to develop an accurate model.</p> <p>The standard requires relays be modeled into the dynamic simulation. While standard mho, distance, or reactance distance relay model may exist, manufacturer-specific relay models often do not. Since this modeling is generally not available, it would be unworkable to develop an accurate dynamic model to test relay loadability.</p>

Voter	Entity	Segment	Vote	Comment
<p>Response: The standard permits an aggregate model assumption that can be applied for a given system that is not substation specific so this is not unworkable. No change made.</p> <p>The SDT has clarified Requirement R4, part 4.3.1, bullet #3 to address your concerns.</p> <p>Requirement R4, part 4.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:</p> <ul style="list-style-type: none"> • Successful high speed reclosing and unsuccessful high speed reclosing into a Fault. • Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. • Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models. 				
Marvin E VanBebber	Oklahoma Gas and Electric Co.	1	Negative	<p>Oklahoma Gas & Electric (OG&E) Comments on Proposed NERC TPL-001-1</p> <ol style="list-style-type: none"> 1.) OG&E feels that the effective dates of R1 and R7 shall become effective 18 months and not 12 months. Some entities budgeting cycles may not be based on 12 months and expenditures may be required by some to be compliant. 2.) OG&E feels that the effective dates of R2 through R6 shall become effective 30 months and not 24 months. This will allow entities adequate time to budget (personnel & tools), train, and perform the required studies. 3.) As others have mentioned, OG&E would like the 60 months extended to 84 months. 4.) Further examination should be conducted to evaluate the feasibility of performing the stability analysis every two years and not annually. 5.) OG&E has concerns for including induction motor representations in the load models without any study or bench-marking activities to meet the requirements of R2.4.1. 6.) The abbreviations of HV and EHV used in Table 1 shall be defined in the "Definitions of Terms Used in Standard" section. 7.) Although Table 1 has been improved, further work is needed to make Table 1 more intuitive. The notes at the beginning and ending of Table 1 seem awkward within the document.
<p>Response: 1. The SDT believes that 12 months is sufficient. This isn't a completely new requirement – entities should be doing this work now for the existing TPL</p>				

Voter	Entity	Segment	Vote	Comment
standards. No change made.				
2. The SDT believes that 24 months is sufficient. This isn't a completely new requirement – entities should be doing this work now for the existing TPL standards. No change made.				
3. The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.				
4. The requirement is for an annual assessment and past studies can be used if qualified as per Requirement R2, part 2.6. No change made.				
5. The standard permits an aggregate model assumption that can be applied for a given system that is not substation specific. No change made.				
6. The EHV/HV differentiation is not meant to be a definition in that it only applies to this standard. No change made.				
7. Without any specific comments to address, the SDT is unable to further address your concerns. No change made.				
Mark Sampson	PacifiCorp	1	Negative	PacifiCorp appreciates the diligence and dedication of the Standard Drafting Team and commends the group for their hard work to bring the proposed standard TPL-001-1 to this level. PacifiCorp believes the overall language of the standard has improved to enhance its readability and the language and format of the Tables now provides some improvement in the understanding of acceptable System performance for the various Planning Events. However, inasmuch as the proposed Standard has improved, we cannot support the approval of this document at this time. The following comments and suggestions are provided in support of a no vote on the TPL-001-1 standard as currently proposed. 1) As currently written our Company does not believe that 60 months is a reasonable time period to build transmission facilities to meet the new performance requirements. Building a transmission line in PacifiCorp's 6 state service areas varies significantly in regional and local planning and review process, permitting, siting, legal challenges, routing, and system path rating process can often take more than 5 years to complete from the time the project is authorized. Though requirement R2.7.3 is included to address situations beyond the control of the Transmission Planner, it leaves to the interpretation of the auditor whether the appropriate actions are being taken to resolve the issue that would continue to allow dropping of Non-Consequential Load or curtailment of Firm Transmission Service. Table 1 - Steady State & Stability Performance Planning Events Category P2 (Single Contingency). Category P2 requires responsible entities to study the opening of a line section without a fault. The standard as written states that the opening of this line section will not result in consequential load
John Apperson	PacifiCorp	3	Negative	
Sandra L. Shaffer	PacifiCorp	5	Negative	
Gregory D Maxfield	PacifiCorp	6	Negative	

Voter	Entity	Segment	Vote	Comment
				<p>loss and no voltage or thermal violations will occur on the BES. . This requirement is applicable to EHV (above 300 kV) and HV (100-300 kV) facilities. PacifiCorp believes that this requirement should not be applicable to all HV facilities. From a reliability perspective, a more effective and efficient method would be a bifurcated functional requirement rather than a voltage requirement. In PacifiCorp's system, and in much of the Western Interconnection, a breaker that opens without a fault in the 115/138 kV system almost never has the potential to cause impacts beyond the local area. In most cases this extremely rare event (the unplanned opening of a breaker without a fault) cannot impact the EHV Bulk Electric System. As such, this requirement (P2-1) is not appropriate at the HV voltage levels. A more appropriate requirement for P2-1 would be to require this performance level only for the EHV portion of the BES and the HV facilities that perform a transmission service in addition to local load service. This should not be a requirement for HV facilities that only provide local load service.</p> <p>2) Table 1-P5 Multiple Contingencies (Fault plus Protection System failure to operate) Normal System. There is a significant change in the system normal performance required for EHV systems from the current performance required in TPL-003 (Category C).</p> <p>This TPL-001-1 version does not allow any Non-Consequential load loss (table 1) or firm Demand (note 9) for EHV systems in the event of protection system failure and delayed clearing. This performance requirement would thus preclude use of existing protection systems that rely on remote clearing of interconnected EHV lines or stations if they provide local load service. As written the standard essentially now requires Category B performance rather than Category C performance for multiple contingencies. It is PacifiCorp's opinion that loss of Non-Consequential load or firm Demand should be allowed for the rare event involving multiple contingencies stated in P5 as long as the load or firm Demand loss is contained and controlled in the local load service area and the event does not impact other interconnected utilities or their loads.</p> <p>3) Table 1 - Steady State & Stability Performance Planning Events Category P5 (Multiple Contingency (Fault plus Protection System failure to operate). Category P5 requires responsible entities to study the Event titled Failure of a single Protection System that results in Delayed Fault Clearing on one of the following: Generator, Transmission Circuit, Transformer, Shunt Device, or Bus Section. It appears that this requirement is an indication that multiple protection system failure is not allowed under the proposed TPL-001-1. This appears to be a requirement for redundant protection systems for all possible events on all voltage levels of the transmission system. It also appears that this requirement is attempting to define what comprises an adequate protection system. As the draft standard is presently written it appears that multiple protection system failures are not included in this part or any part of the draft TPL-001-1 standard. As written, it is PacifiCorp's view that any multiple protection system failure would be categorized as an Extreme Event under the draft TPL-001-1</p>

Voter	Entity	Segment	Vote	Comment
				<p>standard. PacifiCorp contends that the many and varied issues associated with designing appropriate protection systems should be done in the context of the development of a protection system standard and not in the context of TPL-001-1. In fact, there is currently a proposed standard going through the NERC standards development process which goal is exactly that. If the standards drafting team intends to require responsible entities to have 100% redundant protection systems on all of its BES facilities, PacifiCorp contends that this fact should be stated up front in the standard so that all interested parties may become aware of this requirement and provide informed comment. PacifiCorp believes that it is appropriate to wait until the current protection system redundancy standard under development proceeds through the SAR process and approval system, given that this in an important generic issue that affects the entire industry. Notwithstanding the inappropriateness of raising the protection system issue in the context of a planning standard, PacifiCorp believes that any planning requirement that includes the failure of a single protection system that results in delayed fault clearing must have a very clear definition of the terms "single protection system" and "delayed fault clearing" in or for entities to determine what compliance with the standard requires. The draft TPL-001-1 standard does not have clear definitions of these terms, leaving room for considerable latitude for interpretation by various responsible entities, auditors, and compliance enforcement authorities. Clear, specific, and technically defensible language is needed for these terms.</p> <p>4) As drafted the standard TPL-001-1 has added requirement 2.1.5 discussing spare equipment and lead times and inclusion in the "Planning Assessment". The standard in this section is not performance based requirement but an activity based requirement as currently stated under R2 2.1.5. PacifiCorp recommends that the standard should be revised and 2.1.5 removed as it does not directly improve the systems performance requirements nor compliance stated in Table 1.</p>
<p>Response: The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order. Requirement R2, part 2.7.3 - If an entity can demonstrate that they have made a best faith effort to implement the planned solution then there should not be a concern. The wording of the requirement allows an entity this flexibility.</p> <p>The SDT believes that the addition of footnote 12 (when it is finalized) will address your concern.</p> <p>The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>The SDT has changed the text for the P5 event as a result of your (and others) comments to address these concerns.</p>				

Voter	Entity	Segment	Vote	Comment
<p>P5. Delayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed, for a Fault on one of the following:</p> <p>13. Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).</p> <p>The SDT has clarified the requirement based on your comments and those of others.</p> <p>Requirement R2, part 2.1.5 - When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment</p>				
John C. Collins	Platte River Power Authority	1	Negative	<p>Platte River appreciates the efforts and perseverance of the Drafting Team on this important standard. A “no” vote is cast because the following requirements are not clear and have RISKS for different interpretations that could result in non-compliance.</p> <p>(1) Table 1 Planning Events, column for Initial System Condition. Does “Loss of” refer to a planned outage or forced outage?</p> <p>(2) Table 1, Extreme Events, column for Stability. In Stability Event 1, what is the fault type for the first forced outage? (The second forced outage is specified as 3-phase.)</p> <p>(3) Contingency lists required for Planning Events in Table 1. The required scope of contingency analysis for each Category is not clear. P1. Create a list of Contingencies only for the more severe P1 type, or create lists for each of P1-1 through P1-5 types? P2. Create a list of Contingencies only for the more severe P2 type, or create lists for each of P2-1 through P2-4 types? P3. Create a list of Contingencies only for the more severe P3 type, or create lists for each of P3-1 through P3-5 types? P4. Create a list of Contingencies only for the more severe P4 type, or create lists for each of P4-1 through P4-6 types? P5. Create a list of Contingencies only for the more severe P5 type, or create lists for each of P5-1 through P5-5 types? P6. Create a list of Contingencies only for the more severe P6 type, or create lists for each of P6-1-1 through P6-4-4 types, 16 possible combinations? P7. Create a list of Contingencies only for the more severe P7 type, or create lists for each of P7-1 through P7-2 types?</p> <p>(4) Contingency lists required for Extreme Events in Table 1. The required scope of contingency analysis for each Steady State and Stability columns is not clear. Create a list of Contingencies only for the more severe type, or create lists for each of the “such as” types?</p> <p>(5) Table 1, compare footnotes 1, 3, and 5. Does a P4-3 or P5-3 contingency involving an EHV-HV transformer and causing deficiencies on the EHV allow Non-Consequential Load Loss to correct since</p>

Voter	Entity	Segment	Vote	Comment
				<p>the HV is the lowest voltage and override the "No" in the column for Non-Consequential Load Loss Allowed for EHV?</p> <p>(6) What is a "sufficient amount" and how much is a "measurable change" for sensitivity case stressing? See parts 2.1.4 and 2.4.3.</p> <p>(7) Are the actions associated with single vs. multiple sensitivity studies in part 2.7.2 Corrective Action Plans?</p> <p>(8) Are Long-term stability analyses required only if there are generation additions or changes in the long-term horizon? See part 2.5.</p>
<p>Response: 1. Planned outages of six months or more should be incorporated into the PO condition as per the requirements. The events cited are forced outages.</p> <p>2. It doesn't matter what type of Fault creates the first outage condition as it is the second outage that is studied.</p> <p>3. The SDT believes that an entity only needs a list for those types of events that are more severe for your study area.</p> <p>4. An entity doesn't need a list for each 'such as'. The rationale for those selected must be documented as stated in the requirements.</p> <p>5. For an outage of an EHV/HV transformer, performance requirements specified as HV must be met.</p> <p>6. Requirement R2, part 2.1.4 is part of Requirement R2 which mandates that an entity must document all assumptions utilized in the Planning Assessment. No change made.</p> <p>7. Requirement R2, part 2.7.2 is for multiple sensitivities. Requirement R2, part 2.7 states that Corrective Action Plans are not required for single sensitivities.</p> <p>8. Yes, it is required only if there are additions or changes in the long term.</p>				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Negative	Reword Table 1 Note (i) as follows: The response of voltage sensitive load that is disconnected from the system by end-user equipment associated with an event shall not be used to meet steady state performance requirements
Nickesha P Carrol	Consolidated Edison Co. of New York	6	Negative	Reword Requirement R 1.1.5 as follows: Known commitments for Firm Transmission Service, and, additionally, other types of transactions provided they have been demonstrated to not violate existing reliability constraints
Peter T Yost	Consolidated Edison Co. of New York	3	Negative	

Voter	Entity	Segment	Vote	Comment
<p>Response: The header note is not just for disconnections by end-user equipment but would also cover the natural response of Load for voltage reduction. The suggested wording changes the intent of the SDT. No change made.</p> <p>The SDT believes that the defined term 'Interchange' covers other transfers as described in your comment. No change made.</p>				
Henry Delk, Jr.	SCE&G	1	Negative	<p>SCE&G appreciates the efforts of the Standard Drafting Team and believes this version of the TPL standard has addressed most of the significant issues found in previous versions. However, SCE&G believes there are several significant issues that need modification or further explanation.</p>
Hubert C. Young	South Carolina Electric & Gas Co.	3	Negative	<p>1. SCE&G agrees with other submitted comments that the requirement to complete new transmission construction to meet new performance requirements within 60 months is too short. SCE&G believes that 84 months is more reasonable.</p> <p>2. SCE&G agrees with comments submitted by Duke Energy that the requirement prohibiting loss of non-consequential load for P1, P2.1 and P3 events is an overreach by the standard into local load quality of service issues, does not provide any real benefit to Bulk Electric System (BES) reliability, and may have unintended negative consequences on reliability and service quality. In many instances, it may be in the best interest of all involved parties from an overall cost/benefit point of view to allow loss of non-consequential load. The standard should continue to allow Transmission Planners to use discretion regarding loss of non-consequential load, such that Transmission Planners, customers, and local regulators jointly control the decision making when BES reliability is not an issue.</p> <p>3. SCE&G believes there are still different interpretations of Consequential and Non-Consequential Load loss and how each should be applied or not applied. The Standard drafting team should provide several examples in its response to these comments showing how to apply and not apply Consequential and Non-Consequential Load Loss. Without clear examples, SCE&G believes many request for interpretation will be submitted to NERC by the industry.</p>
<p>Response: The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p> <p>The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>The SDT has clarified the issue of Non-Consequential Load Loss as shown above. Providing examples here of what is Non-Consequential Load Loss versus</p>				

Voter	Entity	Segment	Vote	Comment
<p>Consequential Load Loss would have no bearing on eventual compliance findings. The words are what matter and the SDT feels that the clarification provided should alleviate your concern.</p>				
Charles H Yeung	Southwest Power Pool	2	Negative	SPP recommends the standards drafting team review the IRC SRC comments submitted in Oct 2009 and reassess those concerns.
<p>Response: The SDT addressed the comments of the IRC SRC in its responses to the last posting which were captured in the Consideration of Comments report. Without any new specific comments to address, the SDT is unable to further address your concerns. No change made.</p>				
James L. Jones	Southwest Transmission Cooperative, Inc.	1	Negative	<p>SWTC Comments: The SDT has done a lot of good work in developing the TPL 001 standard. However, I agree with the comments of others and suggest that another draft should be produced before the standard is sent to a ballot.</p> <p>SWTC foresees a problem with manpower and the cost of studies for small entities such as ourselves. This will be an extra burden and costs that will ultimately be borne by the consumer who is already not very happy lately.</p> <p>In part 2.7.1, remove the second sentence and all bullets. These are not measurable performance criteria.</p> <p>EHV" and "HV" need to be defined because they are not defined in the NERC Glossary.</p> <p>R4.3.2 This is an admirable goal, and we applaud the SDT's vision. However, modeling all Protection Systems may be beyond the capabilities of presently used dynamic modeling tools. The number of impedance and overcurrent relays that would need to be included for lines and transformers would likely overwhelm these programs. We are concerned that the programs in use may not have the capability to model important relay characteristics such as load encroachment or out-of-step operating characteristics.</p> <p>R5 & R6: Shouldn't the Load Serving Entities (LSEs) define system performance criteria instead of the Transmission Planner or the Planning Coordinator? The LSEs have an obligation to their customers and must demonstrate to their regulators that they are providing acceptable system performance and reliability of supply to their customers. The Transmission Planner and Planning Coordinator have less incentive to provide high levels of system performance. Due to regulatory difficulties in getting approvals for transmission system upgrades, there may be a tendency on the part of TPs and TCs to avoid proposing transmission upgrades, letting system performance degrade instead by abandoning traditional planning criteria and defining less stringent standards for themselves. R6 Remove the "for conditions such as ..." list.</p>

Voter	Entity	Segment	Vote	Comment
<p>Response: The SDT has clarified Requirement R2 and part 2.1 to make it clearer that qualified past studies can be utilized.</p> <p>Requirement R2 - Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.</p> <p>Requirement R2, part 2.1 - The Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, part 2.6, as follows:</p> <p>The listed items are simply that – a list of actions that would be included. This is an allowable and encouraged format for Reliability Standards. No change made.</p> <p>The EHV/HV differentiation is not meant to be a definition in that it only applies to this standard. No change made.</p> <p>The SDT believes that your comment is for Requirement R4, part 4.3.3. The SDT has modified the wording of this requirement to address your concern.</p> <p>Requirement R4, part 4.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:</p> <ul style="list-style-type: none"> • Successful high speed reclosing and unsuccessful high speed reclosing into a Fault. • Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. • Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models. <p>These are System requirements for the BES and properly belong to the Planning Coordinator and Transmission Planner. No change made.</p>				
Donald S. Watkins	Bonneville Power Administration	1	Negative	The Bonneville Power Administration (BPA) acknowledges and appreciates the hard work and diligence of the Standards Drafting team on such a large effort. BPA respectfully submits the following comments.

Voter	Entity	Segment	Vote	Comment
Rebecca Berdahl	Bonneville Power Administration	3	Negative	<p>1. Requirement R1.1.2: BPA recommends that system models should only represent outages with a duration of one year or more. The planning horizon should not cover an outage less than one year because there is not adequate time for developing and implementing any necessary mitigation plan. Known outages with duration less than one year should be dealt with in the Operations horizon. In addition, the near term steady state studies represent year one or year two and year five as required by R2.1.1. Therefore it is not consistent with the rest of the standard to require modeling outages less than one year.</p> <p>2. Requirement R3.5: BPA recommends removing the requirement to evaluate possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the extreme events. o This is more stringent than the existing requirement without providing any increased reliability benefit. The new standard already requires a significant increase of study cases and this additional requirement results in an undue study burden on utilities without adding any benefit.</p>
Francis J. Halpin	Bonneville Power Administration	5	Negative	<p>o In addition, Table 1, Extreme Events, should be reduced to a more prudent list of possible events to evaluate risks and consequences. It is obvious that several of the events, especially under item 3 (Wide Area Events), would cause cascading and it is not practical to evaluate possible mitigation plans for such extreme events.</p>
Brenda S. Anderson	Bonneville Power Administration	6	Negative	<p>3. Table 1: The category P2 Single Contingency should be removed.</p> <p>o Events P2.2, P2.3 and P2.4 should be moved to category P4 since these events are not single contingencies. P2 is a single contingency category, which by definition takes one system component out of service. Bus section faults and bus-tie breaker faults are multiple contingencies since they are events that take multiple system components out of service.</p> <p>o Event P2.1 "opening of a line section w/o a fault" should not be included in the planning standard. At a minimum Event P2.1 should be moved to Category P1 since it is a single contingency and it should allow Interruption of Firm Transmission Service and Non-Consequential Load Loss for the HV (<300 kV) BES level. Many of the HV (115-kV) lines have taps that serve loads and are designed to remove all elements that the protection system and other automatic controls are expected to disconnect. This is consistent with Requirement 3.3.1 which states "Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention." Inadvertent opening of one end of an HV line section without a fault almost never has the potential to cause impacts beyond the local area, yet has a low probability of occurrence and would be very costly in some cases to mitigate.</p> <p>4. Footnote 11: BPA recommends removing the reference to common Right-of-Way. This could be mis-interpreted that a common Right-of-Way longer than 1mile should be planned for under Category</p>

Voter	Entity	Segment	Vote	Comment
				<p>P7. The NERC standards only include common Right-of-Way under extreme events and in this footnote. So, it would be consistent with the rest of the standard to remove this reference from the footnote and possibly make a specific reference in the Extreme Events category where it applies.</p> <p>5. Requirement R2.4.1: BPA agrees with other commenter's concerns that requiring Load models that consider the behavior of induction motor Loads is premature without adequate development and benchmarking efforts. In addition, specific types of models and data required for analysis should not be mentioned here, but should be specified and submitted through the appropriate MOD Standard's.</p> <p>6. Requirement R4.3.3: BPA agrees with other commenter's concerns regarding simulating the impact of transient swings on Protection System operation for Transmission lines and transformers. It would be an extremely burdensome task to model relay impedance characteristics for all elements with little or no benefit, and it is questionable whether the simulation programs would support this effort.</p>
<p>Response: 1. The time frame is for future outages in the planning horizon and last for at least six months. No change made.</p> <p>2. The SDT disagrees as this is effectively the same requirement as presently stated in TPL-004. No change made.</p> <p>The SDT does not agree that these conditions obviously will create Cascading. The SDT reminds the commenter that not all events must be studied. No change made.</p> <p>3. The category descriptions are meant to characterize the events. A single event may remove more than one element from service and that has been addressed in Header note 'c'. The SDT does not believe that there are inconsistencies within the table. The P2 category describes single events that may result in multiple elements being removed from service. The P2 events differ from the multiple event categories which consider two or more sequential events. No change made.</p> <p>4. The SDT has revised the footnote to provide additional clarity based on your comment.</p> <p style="padding-left: 40px;">11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less.</p> <p>5. The standard permits an aggregate model assumption that can be applied for a given system that is not substation specific. No change made.</p> <p>6. The SDT has revised Requirement R4, part 4.3.1, bullet #3 to address this concern.</p> <p style="padding-left: 40px;">Requirement R4, part 4.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:</p> <ul style="list-style-type: none"> • Successful high speed reclosing and unsuccessful high speed reclosing into a Fault. • Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. • Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual

relay models.				
Ralph Frederick Meyer	Empire District Electric Co.	1	Negative	<p>The Empire District Electric Company appreciates the dedication of the Standards Drafting Team. Empire cannot support the approval of the proposed standard as written. Empire finds exception to the proposed standards in the following areas:</p> <ol style="list-style-type: none"> 1) We disagree with the proposed requirement 2.1.5 on spare equipment strategy in that it is discriminatory for smaller entities like Empire. Having a spare transformer is not practical and makes far less sense for a smaller entity but yet has a significant rate impact to our customers. 2) We disagree with requirement 3.3.3 as written would require modeling of nearly every phase distance relay, especially when studying extreme events. The requirement deserves flexibility as allowed in requirement 3.3.2 3) We do not believe 60 months is a reasonable time period to build transmission facilities to meet the new performance requirements. Our suggestion to the drafting team would be some amount of time greater than 7 years (84 months).
<p>Response: The SDT has clarified the requirement based on your comments and those of others.</p> <p>Requirement R2, part 2.1.5 - When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment</p> <p>The SDT agrees that a planner should be able to utilize conservative assumptions and screening methods and doesn't believe that there is anything in the requirement that precludes an entity from doing so. No change made.</p> <p>The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p>				

Voter	Entity	Segment	Vote	Comment
Frank Gaffney	Florida Municipal Power Agency	4	Negative	<p>The Florida Municipal Power Agency (FMPA) appreciates the hard work of the SDT, but, we believe there are significant issues that remain with the standard.</p> <p>FMPA believes that 5 years is not enough time to build significant new transmission lines and believes that 7 years is a more appropriate lead time.</p> <p>FMPA believes that the requirement prohibiting loss of non-consequential load for P1, P2.1 and P3 events is an overreach by the standard into local quality of service issues and does not provide any real benefit to BES reliability. The standard ought to separate what an entity chooses to do for the benefit of its own customers and the impacts it may on the reliability of the BES. FMPA believes that an entity has the right to choose to utilize the existing footnote "b" in the version 0 standards if that choice does not detrimentally impact the ability to provide transmission service to others.</p> <p>FMPA believes that requirement 2.1.5 on spare equipment strategy is discriminatory to smaller entities. Also, Order 693 at Paragraph 1725 states: "... the Commission directs the ERO to modify the planning Reliability Standards to require the assessment of planned outages consistent with the entity's spare equipment strategy". The standard oversteps this direction by not including a consideration of planned outages versus forced outages.</p> <p>Requirements 3.3.3 and 4.3.1 would require modeling of nearly every phase distance relay in the Interconnection. It is questionable whether we have the software tools to do so, and this would require a huge level of effort to maintain an interconnection wide database of relay settings for questionable benefit. FMPA believes that the SDT ought to evaluate the perceived increase in accuracy that is intended with these requirements. It is FMPA's belief that the expected increase in accuracy is lost when considering other simulation inaccuracies that we really cannot improve (e.g., load modeling) until much more work is done on improving our understanding of dynamic load behavior and benchmarking the model to actual system events.</p>
<p>Response: The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Alden Briggs	New Brunswick System Operator	2	Negative	<p>The NBSO applauds the efforts of the Drafting Team on this very important TPL standard. However, we feel that it is not quite ready for acceptance but with a few tweaks and some much needed clarity it would be.</p> <p>NBSO believes the BES versus BPS needs resolution as we much prefer standards that applicable to the bulk power system based on an impact assessment opposed to an arbitrary voltage level.</p> <p>The standard should be more flexible allowing for any trade off between temporarily shedding small amounts of load to recover from a single contingency where the alternative which may force significant transmission upgrades. The standard gives preference to a single line feeding a local area versus two lines, where the loss of one of two under high loading conditions should allow for portions of load to be shed to maintain voltage.</p> <p>The standard considers demand side management as an option but no allowance for instantaneous and temporary load loss that could be required before DSM could be activated. The standard should be clear that if in agreement with a distribution provider some portions of the distribution load (non-consequential load loss) may be shed for a single contingency for undervoltage and underfrequency conditions.</p> <p>The requirements for load models should be clarified so capture dynamic behaviour within reason.</p>

Voter	Entity	Segment	Vote	Comment
				There should be a Q&A guide to allow for examples to clarify the requirements.
<p>Response: The SDT does not believe that it needs to define BES. In its March 18th order, FERC suggested a continent-wide definition of the BES. No change made.</p> <p>The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>DSM is permitted because it is pre-arranged with the customer. For transmission systems, DSM is expected to be used in anticipation of the next transmission system Contingency, not in response to the transmission system Contingency. UVLS & UFLS are intended safety nets for operations and should not be relied upon in transmission planning. No change made.</p> <p>The standard permits an aggregate model assumption that can be applied for a given system that is not substation specific. Dynamic load modeling is important for correct dynamic simulations. Industry has acknowledged the need for accurate Load modeling and the SDT has codified this need in the proposed standard. No change made.</p> <p>While a Q&A providing examples may be helpful it would have no official bearing and such an effort is not in the project schedule.</p>				
Gregory Campoli	New York Independent System Operator	2	Negative	<p>The New York Independent System Operator (NYISO) believes this proposed standard is moving in the right direction with the right intentions, and while we truly appreciate the expertise and hard work that the standards drafting team (SDT) has consistently exhibited throughout this lengthy process, we have voted no on the adoption of this balloted version of the proposed NERC Standard TPL-001-1 for the following reasons:</p> <ol style="list-style-type: none"> 1. The proposed Standard would significantly, and unnecessarily, shift responsibilities away from the Transmission Owner (TO). The proposal would require that for the Bulk Electric System (BES) throughout the New York Control Area (NYCA) the NYISO would annually evaluate: specified contingency events, all corrective action plans, and all spare equipment strategies. As we are not a BES facility owner, we believe that facility specific requirements should stay with facility owners. 2. The proposed Standard requires that Corrective Action Plans are included in each Planning Assessment and states "Such actions may include..." followed by a list of actions. Restricting allowable actions, and excluding runback/tripping of HVDC would have a direct impact on multiple existing facilities in New York and would adversely impact the reliability planning of the NYCA. 3. The proposed Standard would require the PC & TP to assess the impact and probability of the possible unavailability of any piece of equipment with a lead time of one year or more. Such an evaluation of spare equipment strategies would require significant additional resources and data, but

Voter	Entity	Segment	Vote	Comment
				<p>provide no benefit to system reliability, as it is redundant to the existing N-1-1 contingency requirement (P6).</p> <p>4. The proposed Standard would require an “annual” assessment of the system in order for it to be considered “current.” The NYISO has a biennial reliability planning process and does not find it necessary to perform all studies annually in order to be current. We see no reliability benefit to requiring this to be done annually; in fact, dilution of planning efforts and resources is in itself a reliability risk.</p> <p>5. The proposed Standard lacks a clear definition of the first year of the planning horizon. It is defined as the planning window that begins 12-18 months from the end of the current calendar year. If “Year One” is two calendar years out, what is year two? year five? This ambiguity poses an unacceptable risk to compliance.</p> <p>6. For steady-state and stability analysis, the proposed Standard creates a limited list of required sensitivities, and may require sensitivities with no useful objective. The Standard should instead provide a list of suggested sensitivities to allow the planning entity to use its judgment to study sensitivities pertinent to its system. Furthermore, in the absence of a definition of base case conditions, it is difficult to determine, from a compliance standpoint, what is a “stressed” system.</p> <p>7. The proposed Standard requires stability models to represent the dynamic behavior of loads, including the consideration of the behavior of induction motor loads. The NYISO, along with many other systems, has not determined a need to model dynamic loads, and therefore has not benchmarked any such models. The NYISO recommends that prior to this requirement being in place, a modeling standard should exist that is specific to dynamic loads.</p>
<p>Response: 1. Planning the system is the responsibility of the Planning Coordinator and Transmission Planner as per the Functional Model. The Planning Coordinator or Transmission Planner simply needs to account for those strategies and facility specific items that are passed to them by asset owners. No change made.</p> <p>2. The list is not all inconclusive but a list of possible actions. The SDT agrees that runback or tripping of HVDC would be allowable actions. No change made.</p> <p>3. The SDT has clarified the requirement based on your comments and those of others.</p> <p>Requirement R2, part 2.1.5 - When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment</p> <p>4. The intent of the SDT wasn't that annual studies are required but that an annual Planning Assessment is required. However, the SDT agrees that the words</p>				

Voter	Entity	Segment	Vote	Comment
				<p>may have been somewhat confusing. Therefore, the SDT has clarified the wording of Requirement R2 and part 2.1.</p> <p>Requirement R2 - Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies, document assumptions, summarize documented results, and cover steady state analyses, short circuit analyses, and Stability analyses.</p> <p>Requirement R2, part 2.1 - The Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, part 2.6, as follows:</p> <p>5. Based on your comment and those of others, the SDT has revised the definition of Year One.</p> <p>Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For the Planning Assessment started in a given calendar year, Year One must include the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013.</p> <p>6. The SDT has made clarifying changes to Requirements R1 and R2, part 2.1.4 to address your concerns.</p> <p>Requirement R1 - Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use the latest data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes the normal system condition in Table 1.</p> <p>Requirement R2, part 2.1.4 - For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:</p> <p>7. The standard permits an aggregate model assumption that can be applied for a given system that is not substation specific. Dynamic load modeling is important for correct dynamic simulations. Industry has acknowledged the need for accurate Load modeling and the SDT has codified this need in the proposed standard. No change made.</p>

Alan Adamson	New York State Reliability Council	10	Negative	<p>The New York State Reliability Council (NYSRC) appreciates the hard work and time the drafting team has devoted during its preparation this standard. The present version represents a significant improvement over the present transmission planning TPL standards. However, the TPL-001-1 standard needs further improvement in several areas before the NYSRC can vote to approve the standard, as follows:</p> <ol style="list-style-type: none"> 1. The standard requires annual assessment of the system regardless of whether system conditions are essentially unchanged from year to year. This may require unnecessary study work. 2. Testing requirements are rigidly defined in the standard, but specifically what is to be tested is loosely defined. 3. The standard requires analyses of a specific list of sensitivities. Instead, the standard should provide a list of suggested sensitivities and allow the planning entity to use its judgment to study those sensitivities that may be more pertinent to its system. 4. The standard requires stability models to represent the dynamic behavior of loads, considering the behavior of induction motor loads. New York has not modeled dynamic loads, and such modeling has never been benchmarked. For many years, simulations of actual system disturbances have been represented with excellent accuracy, without modeling loads dynamically. 5. The definition of BES (100kv bright line) is uncertain at this time. Therefore, until this definition and its application is resolved, it is not possible to know - without a clarifying provision in the standard - which portion of a system that presently has a performance based methodology, such as the New York State Power System, is subject to the TPL-001-1 standard.
<p>Response: 1. The intent of the SDT wasn't that annual studies are required but that an annual Planning Assessment is required. However, the SDT agrees that the words may have been somewhat confusing. Therefore, the SDT has clarified the wording of Requirement R2 and part 2.1.</p> <p>Requirement R2 - Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. The SDT has made clarifying changes to Requirement R2, part 2.1.4 to address your concerns. <p>Requirement R2, part 2.1.4 - For each of the studies described in Requirement R2, parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to</p>				

Voter	Entity	Segment	Vote	Comment
<p>demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:</p> <p>4. The SDT assumes that you are referring to the induction motor Load modeling required for Stability studies. The standard permits an aggregate model assumption that can be applied for a given system that is not substation specific. Dynamic load modeling is important for correct dynamic simulations. Industry has acknowledged the need for accurate Load modeling and the SDT has codified this need in the proposed standard. No change made.</p> <p>5. The SDT does not believe that it needs to define BES. In its March 18th orders, FERC suggested a continent-wide definition of BES. No change made.</p>				
James Armke	Austin Energy	1	Negative	The proposed TPL-001-1 Standard needs to be revised regarding the comments submitted by Ameren, Duke, and JEA.
<p>Response: Please see responses to Ameren, Duke, and JEA.</p>				
Silvia P Mitchell	Florida Power & Light Co.	6	Negative	<p>The SDT has addressed many of the gray areas of Draft four in their consideration of comments however these comments are not part of the Standard that is currently out for ballot. Incorporating these type of clarifying comments in the Standard with the use of footnotes to clarify the intent would be a significant improvement for anyone interpreting the Standard including an auditor or investigator.</p> <p>The definition of Year One is an unnecessary departure from the planning practices used in most of the Eastern Interconnection. It is recommended the phrase end of the current calendar year be changed to the current calendar year. This change will allow PAs to begin their near term analysis with either next year or the year after as deemed appropriate.</p> <p>The performance requirements of Table 1 do not allow the loss of non-consequential load for single and multiple contingency events. The disallowance of load loss does not provide any real benefit to the reliability of the BES and is an unnecessary overreach into local quality of service issues that are best addressed by State, Provincial or Municipal authorities. There may be circumstances such as high local transmission costs or local opposition to transmission construction where prohibition of non-consequential load loss represents a poor cost/benefit or quality of life tradeoff. Providing a quantitative cap in non-consequential load loss such as 100 MW may be rationale compromise in the goal of limiting load loss for the more probable outage events. Our preference would be to retain the capability of limited non-consequential load loss.</p> <p>Absent this, the 60 calendar month phase in period described in the Introduction section is too short for transmission facilities rated above 300 kV. Approval and permitting of EHV transmission lines is</p>

Voter	Entity	Segment	Vote	Comment
				<p>extremely difficult and time consuming in most parts of the Eastern Interconnection.</p> <p>The phrase any material changes used in requirement R.2.6.2 will effectively cause all Planning Authorities to run all studies every year regardless of minor changes in the model. The overwhelming majority of PAs use a 10 year set of planning models developed annually by Regions or Subregions. These annual sets of planning models will always have some changes.</p> <p>The annual study requirement is especially problematic for Stability and Short circuit studies that require much more engineering time to complete and are much less likely to have results impacted by minor model changes such as different load forecasts. Uncertainty with audit review of technical rationale documentation will serve to focus Transmission Planning engineering resources on short term compliance to an extent that is counterproductive. Requirement 2.5 represents a significant expansion of Stability Studies into the Long Term horizon. In many cases the stability issue in long term scenarios will be with the response of new generating plants to fault scenarios such as a breaker failure event. The protection upgrades needed to mitigate performance issues are easily accomplished in the short term. The uncertainty of compliance judgment of rationale documentation will force a tremendous amount of unnecessary study work. It is recommend Requirement 2.5 be removed.</p> <p>We concur with the SDT's opinion expressed in the most recent consideration of comments that the individual component level evaluation of protection systems and redundancy requirements should be covered under the PRC standards and that the intent of the protection failure contingencies specified in Table 1 is to simulation the failure of a single protection scheme. The event description for the P5 contingency was revised in draft 5 but it continues to reflect a range of protection component failures that greatly exceed the intent of the SDT. The term Protection System is in direct conflict with the intent of the SDT, as it is defined in the Glossary to include components such as station batteries. The term Protection System should be replaced with Protection Scheme in Table 1.</p> <p>Requirement 4.3.1 can be interpreted to require dynamic simulation analysis of multiple fault event scenarios for transmission lines with high speed reclosing enabled. This additional analysis may be advisable for certain rare special situations but is unnecessary and burdensome as a general requirement for transmission planning contingency analysis. As such, requirement 4.3.1 will discourage application of high speed reclosing. This would be an unfortunate outcome given the benefits of high speed reclosing both for transmission reliability and customer power quality. It is recommended that 4.3.1 be reworded as follows; Simulate the operation of Protection Systems and other automatic controls as they would be expected for each contingency.</p> <p>The SDT has indicated in their responses to previous comments on requirement R4.3.3 that generic relay models could be used for screening purposes. While we agree with this as a practical method,</p>

Voter	Entity	Segment	Vote	Comment
				the language of R4.3.3 could be interpreted to require explicit modeling of all protection and controls which is neither practicable nor an effective use of engineering resources. It is recommended that R4.3.3 be deleted.
<p>Response: The SDT has made every attempt to fully clarify the intent of the requirements in response to official specific comments. Without specific references, the SDT is unable to act on your comment. No change made.</p> <p>Based on your comment and those of others, the SDT has revised the definition of Year One.</p> <p>Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For the Planning Assessment started in a given calendar year, Year One must include the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013.</p> <p>The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p> <p>Material change is system specific and difficult to define on a continent-wide basis and is left to engineering judgment with a documented technical rationale as stated in the requirement. Christopher Plantev	Integrus Energy Group, Inc.	4	Negative	<p>The Standard is moving in the right direction, but the following concern is preventing us from voting "affirmative". The timeframe of 60-months (5 year) for implementing Corrective Action Plans (CAP), is insufficient. We believe that the implementation timeframe must be extended to seven (7) years.</p> <p>Requirement 2.7.3, which covers situations that arise beyond the control of the Transmission Planner (TP) or Planning Coordinator (PC), but the proposed language is ambiguous. An auditor could identify many things that could reasonably be within the "control" of a TP or PC but are not covered by NERC standards or a TP / PC's process, procedures or criteria. This discretion leaves entities open to possible non-compliance violation based on an auditor's perception of what they believe should be in the TP / PC's control. In addition, the concept of "control" must be limited to an entities' compliance obligation as a Transmission Planner and/or Planning Coordinator. In other words entities must be allowed the ability identify situations which fall under its "control" as a Transmission Owner, Transmission Operator, Generator Owner or Generator Operator etc. but is beyond the responsibility of its Transmission Planner or Planning Coordinator functions.</p>
<p>Response: The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Greg Lange	Public Utility District No. 2 of Grant County	3	Negative	<p>There appears to be many questions about the correct planning long-term horizon. This alone is enough to vote no and ask the drafting team to reconsider that language and their thought process.</p> <p>Grant also has an issue with section 2.1.5. We are struggling with the phrase "major Transmission equipment" and the example of "a transformer". We think it is very important for equipment that is necessary for bulk transfers on the system or one that if lost would cause harm to a neighboring system to be considered in this planning standard. We don't believe a BPS standard should force prescriptive behavior onto an entity, for customer service issues. If the loss of a transformer only impacts local load, this standard should not contemplate or prescribe what the local entity should do. This leaves to much interpretation up to the auditor. The standard could easily become. "You must have spare transformers in inventory to pass compliance with this requirement".</p> <p>Grant is aware that this standard in version zero addressed customer load. Shame on us for not being more proactive and correcting that issue then. We have a new opportunity to correct it now and we would like to see it done. This and all standards should leave local customer service issues alone and concentrate on performance of the major transfers between generation and large load centers. This is not to say that our utilites will choose to leave load off for a year, just that the decision for how to solve this local problem should remain local.</p>
<p>Response: The SDT is unaware of many questions being raised on the long term horizon. Without specific comments, the SDT is unable to address your concern. No change made.</p> <p>The SDT has clarified the requirement based on your comments and those of others.</p>				

Voter	Entity	Segment	Vote	Comment
<p>Requirement R2, part 2.1.5 - When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment</p> <p>FERC has been quite clear that this standard needs to address the issue of Non-Consequential Load Loss. The SDT has added footnote 12 to address your concerns.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p>				
Mace Hunter	Lakeland Electric	3	Negative	<p>There are two requirements in this Standard that could be interpreted in many different ways and will greatly complicate dynamic simulation studies.</p> <p>4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention while also considering the impact of successful or unsuccessful high speed reclosing.</p> <p>4.3.3. Simulate the impact of transient swings on Protection System operation for Transmission lines and transformers.</p> <p>Most problematic is 4.3.3 which can be interpreted as requiring discrete models of all relays protecting transmission lines and transformers. This is an impossible task. Developing explicit relay models for simulations of even a small subset of BES equipment would be an enormous engineering effort with little or no benefit. The SDT's response to this criticism is, "This does not necessarily require modeling of specific relays. Some dynamic simulation programs include a generic relay model which can easily be applied to every branch in the simulation. If this model shows impedance swings in a branch element, then either take action according to the generic model results or investigate the characteristics of the relays actually used on that line." There are two problems with this response. First, if the SDT wishes to allow for the use of screening methods then this allowance needs to be part of the Standard language. The Standard development comments and responses have no standing once the Standard is approved by FERC as law. A narrow, strict interpretation of the Standard based on requirement language is to be expected from auditors and investigators. A second problem with the above SDT response is that applicability of generic models is subject to technical challenge. The generic model available within PSS/E sets up circular characteristics for each branch element that are fixed percentages of the branch impedance. These fixed, non adjustable percentages are 46% for zone A, 75% for zone B and 110% for zone C. These generic reaches are significantly smaller than loadability limits allowed under the PRC-023-1. The intent of Requirement 4.3.3 would be better served if reworded as follows; "R4.3.3 Consider the impact of dynamic swings on protection systems and model protection operation where appropriate" Requirement 4.3.1 can be</p>

Voter	Entity	Segment	Vote	Comment
				<p>interpreted to require dynamic simulation analysis of multiple fault event scenarios for transmission lines with high speed reclosing enabled. This additional analysis may be advisable for certain rare special situations but is unnecessary and burdensome as a general requirement for transmission planning contingency analysis. As such, requirement 4.3.1 will discourage application of high speed reclosing. This would be an unfortunate outcome given the benefits of high speed reclosing both for transmission reliability and customer power quality. It is recommended that 4.3.1 be reworded as follows; "4.3.1 Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each contingency."</p>

Response: The SDT has modified the requirement to address your concern.

Requirement R4, part 4.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

- Successful high speed reclosing and unsuccessful high speed reclosing into a Fault.
- Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.
- Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

The SDT has revised Requirement R4, part 4.3.1, bullet #3 to address this concern.

Requirement R4, part 4.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

- Successful high speed reclosing and unsuccessful high speed reclosing into a Fault.
- Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.
- Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

Larry Akens	Tennessee Valley Authority	1	Negative	<p>TVA appreciates the work of the ATFN drafting team over the last several years in drafting this new standard. TVA does have concerns on several issues that need to be corrected as we move forward with this standard. Therefore TVA is voting "Negative" on this proposed standard due to the following issues:</p> <p>1. TVA believes that the 5 year implementation plan allowed for "Raising the bar" facilities does not allow sufficient time for TVA to construct the required new facilities. TVA average time for constructing a new 500-kV line is approximately 7 to 10 years, given the lead time on ROW and following all NEPA requirements. If the 5 year implementation plan is not increased, TVA is also concerned about the extensive outages that must take in upgrading 500-kV facilities in order to meet the 5 year requirement. This would require multiple 500-kV outages in the same timeframe which could have a detrimental effect on the overall Bulk Electric System reliability during this construction phase. TVA does understand that the team has added language regarding the TP or PC inability to get the projects completed through no fault of its own; however, there is no guarantee that TVA will be found compliant if all the work cannot be accomplished in this time frame.</p>
George T. Ballew	Tennessee Valley Authority	5	Negative	<p>2. TVA believes that the footnotes b and c that allow for local load drop in the current TPL standards should still be allowed. TVA understands that this is addressed in FERC Order 693; however, the capital improvements to fix many of these issues will have no overall reliability gain for the Bulk Electric System.</p>
Marjorie S. Parsons	Tennessee Valley Authority	6	Negative	<p>3. TVA is concerned that no generating unit shall pull out of synchronism for Planning Event P1, while the standard does allow generator runback/tripping for the same event. TVA believes that this requirement is overly burdensome without providing any material improvement in system reliability. Additionally, R4.1.1 directly conflicts with Table 1, Note a (applicable to both Steady State & Stability) which states "Consequential Load as well as generation loss is acceptable as a consequence of any planning event ... excluding P0." TVA strongly suggests that this loss of synchronism be allowed for P1 or at least add the ability to trip these units for this P1 event by out of step relaying - since other means of tripping the units are allowed - such as thru the use of other actions including Special Protection Schemes as long as the instability does not spread beyond a local area.</p> <p>4. TVA is concerned with the inclusion of battery failures being included in event P5. P5 states "Multiple Contingency Fault plus Protection System failure to operate". TVA understands that the drafting team believes that batteries are not intended to be included in this event; however, station batteries are presently included in the NERC Glossary definition of "Protection Systems." TVA believes that specific language excluding batteries is required for this P5 event in order to prevent future compliance issues regarding this.</p>

<p>Response: 1. The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 kV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p> <p>2. The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p style="padding-left: 40px;">12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>3. The SDT believes that if an entity has a known condition that identifies a generation unit(s) is prone to trip for a single Contingency event then the entity should proactively trip the unit(s) rather than relying on out-of-step protection to trip the unit. The SDT takes this position because of the concern of the possible detrimental effects of loss of synchronism on the overall reliability of the BES. No change made.</p> <p>4. The SDT has changed the text for the P5 event as a result of your (and others) comments to address these concerns.</p> <p style="padding-left: 40px;">P5. Delayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed, for a Fault on one of the following:</p> <p style="padding-left: 40px;">13. Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).</p>				
Lee Schuster	Florida Power Corporation	3	Negative	<p>We appreciate the challenging and time-consuming work that has been done by the Standard Drafting Team (SDT) to draft TPL-001-1 according to the specific requests made by FERC in Order 693. We are supportive of planning, constructing, operating and maintaining the most reliable Bulk Electric System (BES) that is reasonably feasible. We believe that collectively the industry has exhibited excellent BES reliability under existing NERC TPL Standards. For this reason and for others detailed below, we will vote "no" on the proposed standard.</p> <p>1. We do not believe that 60 months is a reasonable time period to build transmission facilities to meet the new performance requirements. This is especially true of EHV projects. Ameren recently stated in an email to the RBB that "[b]uilding a transmission line in Illinois is estimated to take 7 years (84 months) from the time the project is authorized." In our own experience, we have been limited by permitting and local government processes to the extent that even 69 kV, 115 kV and 230 kV line projects are taking longer than 60 months. We therefore agree with Ameren's point that building of a new EHV transmission line can be a very lengthy process. We think that a more</p>
Sam Waters	Progress Energy Carolinas	3	Negative	

Voter	Entity	Segment	Vote	Comment
Wayne Lewis	Progress Energy Carolinas	5	Negative	<p>appropriate time frame would be 84 months, with provisions to limit or waive fines if a Transmission Owner can demonstrate that the implementation process was unavoidably impeded by permitting, environmental or governmental processes.</p> <p>2. As has been stated in all four commenting periods by Progress as well as certain other registered entities, we believe that the requirement prohibiting loss of non-consequential load for events in Table 1 of TPL-001-1 is an inappropriate overreach by the standard into local load quality of service issues that are already adequately regulated by states' Public Service/Utility Commissions, and does not provide any benefit to BES reliability. The approach of prohibiting the shedding of even a single distribution feeder amounts to feeder reliability rather than BES reliability. This approach, if allowed to be in the Standard, may result in unintended negative results in BES reliability. We therefore appeal to the SDT to discuss this issue with NERC and FERC given the numerous utilities that share this concern. The standard should continue to allow Transmission Planners to use discretion regarding loss of non-consequential load.</p> <p>3. Requirement R4.1.1 states in part that "for planning event P1: No generating unit shall pull out of synchronism." This requirement is overly burdensome without providing any material improvement in system reliability. Additionally, R4.1.1 directly conflicts with Table 1, Note (a) (applicable to both Steady State & Stability) which states "Consequential Load as well as generation loss is acceptable as a consequence of any planning event ... excluding P0." Clearly, the intent the TPL-001-1 standard is to maintain the integrity and reliability of the overall grid, not any particular element. In other words, throughout the standard it is acceptable to lose any generator, load, line or other element as long as more wide reaching consequences are precluded (i.e., cascading outages, non-consequential load loss, etc. is not allowed). As written, R4.1.1 would not allow the use of out of step protective relaying as a solution to trip an unstable generator for a P1 event. It does allow tripping of the same generator due to "fault clearing action" (such as for a fault on the generator terminals) or "by a Special Protection System". Therefore the loss of the generator itself must be acceptable. The notion that preventing loss of synchronism events is the only acceptable means of also precluding more widespread (and unacceptable) consequences resulting from the effect of stability swings is not valid. For some generating units (particularly small, remotely located units) these other unacceptable consequences may not even occur. Also, other means, such as out of step blocking of transmission lines applied in conjunction with out of step generator tripping, may be an effective solution. Any of these solutions is allowed for events P2 through P7 in requirement R4.1.2. We recommend that Requirement R4.1.1 be deleted and R.4.1.2 be revised to include events P1 through P7. Given the concerns raised above, we respectfully request that the SDT make the suggested improvements to TPL-001-1 and continue the process toward approval of the Standard.</p>

<p>Response: The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.</p> <p>The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.</p> <p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p> <p>3. The SDT believes that if an entity has a known condition that identifies a generation unit(s) is prone to trip for a single Contingency event then the entity should proactively trip the unit(s) rather than relying on out-of-step protection to trip the unit. The SDT takes this position because of the concern of the possible detrimental effects of loss of synchronism on the overall reliability of the BES. No change made.</p>				
Jason L Marshall	Midwest ISO, Inc.	2	Negative	<p>We are voting negative for several reasons.</p> <ol style="list-style-type: none"> 1. We believe Requirement 2, Part 2.1.5 is an administrative requirement that is not consistent with the NERC BOT approved results/performance based standards effort. Furthermore, the additional reliability benefit is not clear to us. 2. We believe that Requirement 2, Part 2.3 should only be implemented when there is another requirement in the PRC standards for Transmission Owners and Generation Owners to supply the necessary protection information. 3. We believe that that Requirement 2, Part 2.4.1 needs to be further clarified that the dynamic behavior of load model is an estimate only based on engineering assumptions. As written now, it is not clear how much deviation is allowed from actual system operation. 4. We believe Requirement 4, Part 4.3.2 should not be implemented until there is a requirement for the Generator Owners/Operators to supply their generator low voltage ride through capability. 5. We believe Requirement 4, Part 4.3.3 should be further refined to clarify that the purpose is to screen zone 3 relay issues. As written now, it appears that zone 3 relays must be modeled in detail because it is not clear that the intent is to only screen potential problems. We are basing our comments on the drafting team's responses to previous comments that they view using generic zone 3 relay models in PSS/E is acceptable.
<p>Response: 1. The SDT disagrees that this is an administrative requirement as it does not state that you must develop a strategy; it states that you must consider the strategy in your planning. Therefore, it has a direct bearing on the reliability of the BES. No change made.</p> <p>2. This standard describes what must be done and not how to do it. The SDT expects that the information cited could be obtained through several different</p>				

Voter	Entity	Segment	Vote	Comment
<p>mechanisms such as delegation agreements or data requests. No change made.</p> <p>3. The SDT has added the word 'expected' to the text to alleviate your concern. Planning models are based on the best information available to the planners at the time of the study and it is well understood that they may not exactly represent actual conditions at any given time. The results of on-going benchmarking and model development activities can be incorporated when those activities yield more representative results.</p> <p>Requirement R2, part 2.4.1 - System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.</p> <p>4. This standard describes what must be done and not how to do it. The SDT expects that the information cited could be obtained through several different mechanisms such as delegation agreements or data requests. No change made.</p> <p>5. In the summary considerations in draft 4 of this project, the SDT indicated that generic relay models can be applied. If this model shows impedance swings in a branch element, then one can either take action according to the generic model results or investigate the characteristics of the relays actually used on that branch. In this draft, the SDT has clarified the requirement for the use of generic relay models.</p> <p>Requirement R4, part 4.3.1 - Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:</p> <ul style="list-style-type: none"> • Successful high speed reclosing and unsuccessful high speed reclosing into a Fault. • Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made. • Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models. 				
Brenda L Truhe	PPL Electric Utilities Corp.	1	Negative	We are voting 'no' on this ballot as this revision proposes to expand contingency requirements beyond traditional planning levels (example - stuck breaker AND protection failure).
Mark A. Heimbach	PPL Generation LLC	5	Negative	
<p>Response: The SDT agrees that new expectations are contained within the requirements aimed at improving BES reliability. An implementation plan has been created to allow for the industry to comply with the new requirements.</p>				
Terry L. Blackwell	Santee Cooper	1	Negative	We disagree with the proposed definition of Year One. We believe that Year One should be the planning window that begins 12-18 months from the start of the current calendar year, and not from

Voter	Entity	Segment	Vote	Comment
Zack Dusenbury	Santee Cooper	3	Negative	the end of the calendar year. We believe that following this modification to the definition would require minimal adjustments to the ERAG MMWG model building process, which we all use as the basis for our planning models. Following the proposed definition would require additional models to be built by the MMWG or lead to holes in the model building effort for both the operating and planning horizons.
Suzanne Ritter	Santee Cooper	6	Negative	<p>SCPSA does not believe that 60 months is a reasonable time period to build transmission facilities to meet the new performance requirements. In an email to the registered ballot body, Ameren stated " Building a transmission line in Illinois is estimated to take 7 years (84 months) from the time the project is authorized." SCPSA agrees with the point that Ameren is making that building of a new EHV transmission line can be a very lengthy process. SCPSA thinks that a more appropriate time frame would be 84 months.</p> <p>SCPSA believes that the requirement prohibiting loss of non-consequential load for P1, P2.1 and P3 events is an overreach by the standard into local load quality of service issues, does not provide any real benefit to Bulk Electric System (BES) reliability, and may have unintended negative consequences on reliability. Often, corrective actions to mitigate these events are local in nature and only require minor additional loss of local load to avoid major projects. The standard should continue to allow Transmission Planners to use discretion regarding loss of non-consequential load, such that Transmission Planners, customers, and local regulators jointly control the decision making when BES reliability is not an issue. The transparency requirements of the new standard facilitate this type of decision making. In addition, the prohibition on non-consequential load loss for these events creates an incentive for Transmission Planners to remove lines serving load from network (serve the loads radially) so that they are characterized as consequential load. The unintended consequence of the standard would be a reduction in reliability for service to local load.</p>

Response: Based on your comment and those of others, the SDT has revised the definition of Year One.

Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For the Planning Assessment started in a given calendar year, Year One must include the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013.

The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order.

The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.

Voter	Entity	Segment	Vote	Comment
<p>12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.</p>				
Thomas C. Mielnik	MidAmerican Energy Co.	3	Negative	We find P5, Multiple Contingency (Fault plus Protection System failure to operate) to be confusing. What analysis is required for this? Analysis of individual Protection System component failures or something else? Do the benefits justify this requirement?
<p>Response: The SDT has changed the text for the P5 event as a result of your (and others) comments to address these concerns.</p> <p>P5. Delayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed, for a Fault on one of the following:</p> <p>13. Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).</p>				
Ajay Garg	Hydro One Networks, Inc.	1	Negative	We thank the Standard Drafting Team for their long and dedicated effort to develop this standard. At this time, Hydro One has decided to cast a negative vote with the following comments:
Michael D. Penstone	Hydro One Networks, Inc.	3	Negative	<p>1. Note 3 in Table 1 refers to EHV Facilities (above 300 kV) and HV (300 kV and lower voltage systems) The standards uses this threshold to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss. We suggest the following be added to this note: "In the region(s) or area where there is a performance based methodology in place to determine Bulk Electric System (BES) elements (e.g. NPCC), only the BES portion of the system is subject to the Standard."</p> <p>2. The Standard repeatedly uses the capitalized term "Firm Transmission Service (FTS)." The NERC Glossary of Terms defines FTS as "The highest quality (priority) service offered to customers under a filed rate schedule that anticipates no planned interruption." We believe that the use of this term and that of "Transmission Service" in TPL-001-1 should be revised as they do not have the same meaning in all jurisdictions. A clarification within the standard will eliminate this confusion.</p> <p>3. The Effective Date Section in the proposed standard gives a time of 60 months to implement certain Corrective Actions. We believe this Standard should not explicitly define timelines (5 years in this case) for transmission projects. Regulatory approvals for new or modified transmission systems may take a significant time in some jurisdictions. We suggest changing the wording to say that Transmission mitigation measures for the reliability of the Bulk Electric System must be implemented as soon as practical exercising due diligence. Progress of and/or delays associated with critical project(s) impacting BES reliability should be submitted to the respective regions and NERC. We recognize that Requirement 2.7.3 covers situations that arise beyond the control of the Transmission Planner (TP) or Planning Coordinator (PC), but we believe that the proposed 60 months timeline</p>

Voter	Entity	Segment	Vote	Comment
				should be removed.
<p>Response: This standard applies to the BES. If there are areas of your system that are not BES, then the standard doesn't apply to them. This would be true even if those elements are above 300 kV. No change made.</p> <p>The SDT reviewed the use of Firm Transmission Service and believes that the term is used correctly in the standard. No change made.</p> <p>The SDT has changed the majority of the implementation timeframe from 60 to 84 months as per your (and others') suggestion. Since problems may not be seen until after the assessments are completed and there is a 24 month implementation for assessments, the total time for items P2-1, P2-2 and P2-3 (above 300 kV), P3-1 through P3-5, P4-1 through P4-5 (above 300 kV), and P5 (above 300 KV) has been increased to 84 months. P1-2 and P1-3 were not increased since they are already being covered by the implementation plan for Project 2010-11: TPL Table 1 Order. Requirement R2, part 2.7.3 - If an entity can demonstrate that they have made a best faith effort to implement the planned solution then there should not be a concern. The wording of the requirement allows an entity this flexibility.</p>				
Mark Ringhausen	Old Dominion Electric Coop.	4	Negative	While the SDT has made progress in their changes from the first draft, there are still some areas that need to be clarified. Others are proving more specific comments (PJM) so look for their comments and address.
<p>Response: Please see response to PJM.</p>				

Voter	Entity	Segment	Vote	Comment
Richard Salgo	Sierra Pacific Power Co.	1	Negative	<p>While we greatly appreciate the work of the SDT, and feel that this Standard has achieved significant improvement, there are a number of issues precluding our approval as written:</p> <p>Spare Equipment: need a clarification on what the "assessment" of the impact of equipment availability entails. For instance, is the assessment a simple narrative of the necessary operational mitigation, engineering analysis of the impact, or on the other extreme, is it a full repeat of the NERC study work for all potential permutations of long lead-time equipment?</p> <p>We have difficulty accepting the language regarding the loss of non-consequential load. As written, this creates a disincentive for the implementation of incremental reliability improvements in the network; ie, creation of a parallel path that does not fully provide redundancy to load service would drive a violation of the requirement.</p> <p>Lastly, the treatment of firm transmission service from the standpoint that it cannot be curtailed under various contingencies is problematic. As written, it would appear that the single-contingency loss of a contract transmission path would require continuance of the firm transmission service via some alternate parallel path. Such methodology would require all such paths to have redundancy via parallel transmission or result in dramatic reductions in transfer ratings.</p>

Response: The SDT has clarified the wording of the requirement and believes that this will address your concern.

Requirement R2, part 2.1.5 - When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

The SDT has added footnote #12 to P1, P2-1, and P3 to address your and others concerns in this area.

12. Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.

Footnote 9 states the conditions for when Firm Transmission Service may be curtailed. If what you are describing is actually Conditional Firm, then see footnote 4. No change made.

Informal Comments on Assess Transmission Future Needs – Project 2006-02.

The TPL-001-2 standard for Assess Transmission Future Needs (Project 2006-02) Drafting Team thanks all commenters who submitted comments on the fifth draft overview. These standards were posted for a 30-day public comment period from August 3, 2010 through September 2, 2010. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 7 sets of comments, including comments from 77 different people from approximately 69 companies representing 6 of the 10 Industry Segments as shown in the table on the following pages.

<http://www.nerc.com/filez/standards/Assess-Transmission-Future-Needs.html>

The SDT has completed the review of the informal comments from industry for Project 2006-02: Assess Transmission Future Needs. Each and every comment was reviewed and considered by the SDT regardless of whether there is a formal written response shown. The majority of the cases where the SDT did not make a change or provide a written response was because the SDT had already responded to the issue or the SDT did not believe that the proposed revision added clarity or otherwise improved the quality of the proposed standard.

The SDT made a number of changes due to the comments received from industry and drafting team discussions arising from those comments as highlighted below:

- Year One definition – deleted ‘must’
- Conforming changes to the language in the Effective Date – made language consistent with the Implementation Plan
- Requirement R1 and M1 – changed, “. . . the latest data consistent with . . .” to “data consistent with. . .” and established P0 as normal System condition in Table 1
- Requirement R2, part 2.1.4 – replaced ‘performance’ with ‘System response’ and changed last bullet from “. . . planned Transmission outages” to “. . . known Transmission outages”
- Requirement R2, part 2.6.2 – require documentation explaining material changes
- Requirement R2, part 2.7.1 – made it clear that statement is not all inclusive
- Requirement R2, part 2.8.2 – made language consistent with Requirement R2, part 2.7.4
- Requirement R4, part 4.3.1, bullet #1 – added qualifier for high speed reclosing
- Requirement R6 and M6 and data retention for R6 – changed ‘any’ to ‘the’
- Table 1, header note ‘i’ – deleted ‘including Load’
- Table 1, P0 – delete superscript in column 6
- Table 1, P2 – added ‘Breaker’ to description
- Table 1, P4 – added ‘Breaker’ to description
- Table 1, P5: added ‘non-redundant’
- Table 1, extreme events – Stability: made language consistent with Table 1, P5
- Measure M8 – spelled out the functional entity involved
- Data retention for Requirement R7 – deleted ‘all such’
- Changed, “Initial System Conditions” to “Initial Conditions” in column heading of Table 1 and Table 1 Note 9
- Deleted section, “Compliance Monitoring and Reset Timeframe as this is no longer included in the standard template.

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs — Project 2006-02

The SDT believes that with these changes, the industry concerns have been addressed except for Footnote 12 (content of existing footnote b). Until the issues with footnote 'b' in Project 2010-11: TPL Table 1 are resolved, the SDT will not request the Standards Committee to move the project to the ballot phase. This could mean that Project 2006-02 may sit in limbo for several months pending the outcome of the Project 2010-11 deliberations. So that industry can see what has transpired with regard to their comments on Project 2006-02, the SDT is requesting that the consideration of comments document, along with the redlined version of TPL-001-2 corresponding to those comment responses be posted immediately. In this way, the industry can see what the SDT has decided in response to comments while the content of the comments is still fresh in the minds of the commenters. The SDT encourages anyone reading the posted documents to reach out to members of the SDT for informal discussions of posted documents.

Once Project 2010-11 is resolved, the wording for footnote 'b' will be essentially copied to TPL-001-2. The SDT realizes that this cannot be a simple cut and paste due to format differences between the old standard and the revised TPL-001-2 and will take appropriate actions to make things fit correctly. Once this has been accomplished, the SDT expects to ask the Standards Committee to move Project 2006-02 to the ballot stage.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.¹

¹ The appeals process is in the Reliability Standards Development Procedures: <http://www.nerc.com/standards/newstandardsprocess.html>.

1. The SDT has revised the Implementation Plan based on industry comments to the initial ballot. Do you support this change? If you do not support this change, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

The majority of respondents agree with the changes to the Implementation Plan and no further changes to the Implementation Plan are deemed necessary.

The SDT fully realizes that Project 2010-11 ([Table 1 - footnote "b"](#)) must reach resolution prior to finalizing TPL-001-2 and stated [the](#) same in the information attached with the fifth posting of Project 2006-02.

The SDT reviewed the comment on consistency of language in the Implementation Plan and the Roadmap and agrees with the comment. The paragraph under Effective Date in the standard has been changed accordingly.

For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval, [or in those jurisdictions where no regulatory approval is required on the first day of the first calendar quarter 84 months after Board of Trustees adoption](#), Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-2, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-2:

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments. In many of the cases relating to the comments, the SDT has already responded to similar comments and those responses are quoted here for convenience:

1.1.5 – “The SDT believes that the base cases should include any area interchange that is planned between utilities.” In addition, non-firm transactions are not required to be modeled.

2.1.5 – “When a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the “normal” (P0) condition in Table 1 and the rest of Table 1 will be applied as stated. This requirement is intended for the Planning Coordinator and/or Transmission Planner to take into account its spare equipment strategy for long lead time Equipment when assessing the performance of its System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Actions such as out of merit dispatch, operational restrictions, System reconfiguration can be part of a Corrective Action Plan if the System cannot meet performance requirements without the Facility in service.”

2.3/2.8 – “is intended for the Planning Coordinator and/or Transmission Planner to assess whether circuit breakers supporting the BES have interrupting capability for Faults that they will be expected to interrupt. Even though the effects of short circuit capability are localized and may be related to new planned Facilities, it is important to BES reliability.”

3.4.1/4.4.1 – “The SDT has determined that it is necessary for the Planning Coordinator and Transmission Planner to coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list created.” In addition, the SDT wants to make it clear that an entity is responsible for corrective actions on its own System.

4.3.1 – “does not require modeling of Protection System equipment. It just requires you to have simulations which include the effects of Protection System equipment operation. You don't have to specifically model a relay to simulate the effect of clearing a fault at 3 cycles. If you need to model a relay to capture its effect, then model that relay. And certainly engineering judgment should be used to determine which relay effects should be included in the simulations.”

References to TPL-001-1 are a typo and will be cleaned up. The correct reference, as pointed out, is TPL-001-2.

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council Consolidated Edison Co. of New York, Inc	No	Requirement R1 Part 1.1 and following states “System models shall represent... 1.1.5. Known commitments for firm Transmission Service and Interchange. It was commented during a previous posting that 1.1.5 should be reworded to read: Known commitments for Firm Transmission Service, and, additionally, other types of transactions provided they have been demonstrated to not violate existing reliability constraints. The response was that “The SDT believes that the defined term ‘Interchange’ covers other transfers as described in your comment. No change made.”It is agreed that known Interchanges should be modeled. However, it is imperative that existing reliability constraints not be violated in the process. That is, Interchange relating to economic transactions should not drive planning studies. Reliability related investments should not be driven by congestion related to economic transactions incorporated into planning models. Following is a preferred/revised wording: o 1.1.5. Known commitments for firm Transmission Service and Interchange. Interchange is meant to refer to energy transactions other than firm Transmission Service. While rigorous planning studies have been conducted to permit the uninterrupted implementation of firm Transmission Service without jeopardizing the reliable operation of the Interconnected System, other types of energy transaction only take place whenever system conditions permit them. They are usually of very short duration relative to planning assessment periods (usually spanning for a few hours to a few days) and deemed highly interruptible subject to reliability issues that may arise during operation of the system. In other words, the term Interchange refers to economic transactions that are permitted when the system is secure and there are reasonable reliability margins to effect dispatch changes to lower operating costs. As such, Interchange should not be reflected in system representation meant to assess system reliability in adherence to reliability criteria delineated in documents such as TPL-001.

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs — Project 2006-02

Organization	Yes or No	Question 1 Comment
GDS Associates, Inc.	No	<p>We disagree with the Implementation Plan and we suggest changes as follows:- The title should read “Implementation Plan for TPL-001-2”- With regards to the Prerequisite Approvals, NERC project #2010-11 still in progress (Table 1, Footnote ‘b’) must be implemented before this current TPL-001-2 standard gets implemented. However, while the 2010-11 NERC project does not define any of the new terms such as consequential / non-consequential load, the footnote ‘b’ cannot be just copied into the new standard (see TPL-001-2 standard Table 1, note 12). Note ‘b’ may further change to reflect the verbiage in the TPL-001-2 standard.-</p> <p>Not sure what is the intent of the last paragraph. While the proposed changes to Table 1, footnote ‘b’ are quite precise, are we still open a door to those entities that will continue to trip Non-Consequential Load and curtail Firm Transmission Service? If no penalties for such practices while the proposed standard allows a sufficient time frame to correct any deficiencies, then what is the point to all the effort behind the development of a new TPL standard?</p>
SMUD		<p>R2.7.1, last bullet: Please provide specifics on the types of acceptable ‘Corrective Actions’ covered by ‘rate applications and DSM’ and the planning horizon for which they are considered acceptable. As an alternative, NERC should develop a process by which what is considered acceptable is published and continuously updated. (With due apologies for not raising this point earlier).</p>
Western Electricity Coordinating Council	Yes	<p>We commend the SDT for its work to continue the improvement on the proposed TPL-001-1. We were not able to find a place to include comment on various requirements not identified in the questions below; therefore, we have included our comments here: Requirement and 2.6 and 2.6.1: A study that is five years old is very likely to be out of date. The entity’s BES may have not changed much in five years but the entity cannot be certain whether or not their neighbor’s system may have changed. Changes outside the immediate entity’s system can impact results of studies within their system. Suggest that two years is a maximum that past studies should be allowed.</p> <p>Requirement 3.4.1 and 4.4.1 require PCs and TPs to coordinate with adjacent PCs and TPs to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list. Please clarify whether this means that a PC or TP must coordinate with others to identify contingencies on other Systems that the PC or TP must now include on their Contingency list to simulate and address any performance violations on their own System, or does it mean that the PC or TP must coordinate with others to identify contingencies on their System that the PC or TP must now include on their Contingency list to simulate and address any performance violations on other Systems. In either case, the standard does not seem to clearly state what must be done, or whose responsibility it is to mitigate, if a contingency in one System causes a performance violation in another System.</p> <p>Requirement R4.3.1, bullet point 3 requires the stability analyses to include the impact of subsequent “[t]ripping</p>

Organization	Yes or No	Question 1 Comment
		<p>of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models”. As written, this bullet could be interpreted as requiring the inclusion of these relay models in stability data bases. We do not have generic or actual relay models in our dynamics data bases for tripping line faults on lines and transformers represented. We represent actual relay response and tripping times of relays, communications, and breakers to faults in tripping transmission lines and transformers. Requiring the inclusion of generic or actual relay models for all relays that can trip lines and transformers would add a large burden to the development and maintenance of accurate dynamics model files that would add little or no benefit. Please change this bullet to read: “Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on known Protection System response”.</p>
Tucson Electric Power Company	Yes	<p>We commend the SDT for its work to continue the improvement on the proposed TPL-001-1. We have included additional comments here since we were not able to find a place to include comments on the following: Requirement R4; Requirement, Parts 2.1.5, 2.3, and 2.8; Requirement 3, Part 3.3.2; and Requirement 4, Parts 4.3.1 and Part 4.3.2</p> <p>Requirement 2, Part 2.1.5: The spare equipment strategy does not improve reliability performance. If an outage of a long lead time piece of equipment occurs, the system should still be able to operate in a reliable manner that meets the performance measures of Categories P3 and P6. If an entity cannot meet its performance requirements under this standard, a capital project is indicated. Spare equipment being available would not mitigate this need it only increases expenses until the item is needed.</p> <p>Requirement 2, Parts 2.3 and 2.8: Short circuit fault duty is a localized phenomena that is mainly impacted by the addition of new generation or transmission facilities. Due to proprietary concerns of generation and transmission interconnection requests, short circuit studies are performed in forums outside the annual Planning Assessment. Normally, these studies will be conducted before the projects can be included in regional base cases. As such, short circuit analysis should not be included in this Standard since it would provide limited benefit.</p> <p>Requirement 3, Part 3.3.2 and Requirement 4, Part 4.3.2 Steady state response of dynamic control devices should also be included in the Part 3.3.2. and the list of possible devices included should be removed from Part 3.3.2 and 4.3.2.</p> <p>Section R4.3.1, bullet point 3 requires the stability analyses to include the impact of subsequent “[t]ripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models”. As written, this bullet could be interpreted as requiring the inclusion of these relay models in stability data bases. We do not have generic or actual relay models in our dynamics data bases for tripping line faults on lines and transformers represented. We represent actual relay response and tripping times of relays, communications, and breakers to faults in tripping transmission lines and transformers. Requiring</p>

		the inclusion of generic or actual relay models for all relays that can trip lines and transformers would add a large burden to the development and maintenance of accurate dynamics model files that would add little or no benefit. Please change this bullet to read: “Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on known Protection System response”.
Western Area Power Administration	Yes	<p>The whole bullet point section in the Effective Date section referring to Corrective Action Plans could be deleted and instead captured by Requirement R2.7.3. A seven year grace period is probably not favorable to FERC, and a better solution could be developed to meet industry needs. In R2.7.3, a possible example of "beyond the control of the Transmission Planner" could be that the physics of a significant percentage of induction motors in low inertia air-conditioning loads would tend to pull out for certain N-1 events. This may in significant part occur because such motors may have nearly no dynamic stability margin to withstand such N-1 events as close-in 3-phase faults with normal clearing during peak load conditions. So until the Transmission Planner has been able to institute changes in the industry to address the basic physics of such loads, this Requirement 2.7.3 would permit the use of such "Non-Consequential" Load Loss and curtailment of Firm Transmission Service. In this example, it may take longer than a seven year time period to fix the problem. On the other hand, some examples of Non-Consequential Load Loss could perhaps be mitigated in a shorter timeframe. Provided that an entity has a good technical justification and defined margin for “Non-Consequential” Load Loss or curtailment of Firm Transfers, then it may be acceptable. Requirement R2.7.3 seems to move in this direction.</p> <p>Section R4.3.1, bullet point 3 requires the stability analyses to include the impact of subsequent “[t]ripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models”. As written, this bullet could be interpreted as requiring the inclusion of these relay models in stability data bases. We do not have generic or actual relay models in our dynamics data bases for tripping line faults on lines and transformers represented. We represent actual relay response and tripping times of relays, communications, and breakers to faults in tripping transmission lines and transformers. Requiring the inclusion of generic or actual relay models for all relays that can trip lines and transformers would add a large burden to the development and maintenance of accurate dynamics model files that would add little or no benefit. Please change this bullet to read: “Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on known Protection System response”.</p>
NERC staff	Yes	NERC staff supports the change to allow Corrective Action Plans to include tripping of Non-Consequential Load and curtailment of Firm Transmission Service for 7 years. This seems long, but staff understands the stakeholder concern that it could take that long to plan, site, and construct facilities required for compliance with the standard.
SERC Dynamics Review	Yes	“The comments expressed herein represent a consensus of the views of the above named members of the SERC Engineering Committee Dynamics Review Subcommittee only and should not be construed as the

2. The SDT has revised the definition of Year One based on industry comments to the initial ballot. Do you support this change? If you do not support this change, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

The majority of respondents agree with the changes to the Year One definition but there was one change made due to industry comments for consistency of terminology.

Year One: The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For the Planning Assessment started in a given calendar year, Year One ~~must include~~ the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One ~~must include~~ the forecasted peak Load period for either 2012 or 2013.

The SDT acknowledges the concerns expressed by a minority of commenters on ambiguity of wording, embedding the definition in the requirements, and use of operating horizon studies. However, the SDT believes that the definition has been vetted through numerous industry comment periods and that it now represents a reasonable definition for a continent-wide standard while still providing a level of flexibility for the planner.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 2 Comment
Northeast Power Coordinating Council	No	The definition of Year One could be eliminated, and its wording used in place of Year One within the text of the requirement. The proposed definition has now added ambiguity with respect to “year two” and “year five” which are not defined. Year two could be deleted and R.2.1.1 modified as follows: System peak Load representing a point in time 12-24 months and another point in time 48-65 months into the future from the time the study is initiated. Define Year Five as the twelve month period 4 to 6 calendar years from the date of the Planning Assessment.
ISO New England Inc.	No	The definition of Year One could be deleted and used in place of Year One within the text of the requirement. The proposed definition has now added ambiguity with respect to “year two” and “year five” which are not defined. Year two could be deleted and R.2.1.1 modified as follows: System peak Load representing a point in time 12-24 months and another point in time 48-65 months into the future from the time the study is initiated.

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 2 Comment
Western Electricity Coordinating Council	No	We recognize that the drafting team made changes to the definition of Year One based on industry comments. However, we believe that the revised language could allow for a situation where an entity could use its next season's operating study as its Year One planning study. For example, if the entity does its study in the fall of 2011, the proposed definition would allow the entity to use its summer 2012 operating study as its Year One study. This is a very short period to address any issued identified. Suggest working into the requirement that Planning Studies must look out at least 12 months beyond when the study is performed. This would still allow for the provision in the current definition example ("if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013) because the entity would be able to use their 2013 Load period, but it would prevent the entity from using the 2012 Load period if they started the assessment late in 2011.
E.ON U.S.	No	Comments: 2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected. E.ON U.S. believes the scope of the 'current study' should be defined. It is not clear whether the scope is the same as outlined in section 2.1.
Florida Reliability Coordinating Council, Inc - Transmission Working Group	No	No, because it is worded to be dependent upon when an assessment is started rather than when the assessment is completed and valid. Assessments don't typically include a "start date". An assessment completed on a calendar date should include (be valid for) the forecasted peak load for a timeframe that begins no more than 24 months from the date that the assessment was completed.
Lakeland Electric	No	<p>"the latest" is not needed from the second sentence of R1, since the sentence already ended with "...shall represent projected System conditions".</p> <p>R1 Part 1.1.2 Suggest adding this clarification at the end "... six months during the period under study". This language addition helps clarify the point that if an outage occurs during the summer and the entity's system peak occurs in the winter, then the system peak Load study case (model) does not have to include this particular outage.</p>
Seattle City Light	No	The definition of Year One is now too flexible and does not meet the intent of the standard. For example, our system peak is generally in January of the year. If I perform TPL studies in November 2011, studying the peak in January 2012 is acceptable according to the new definition. This is only two months from the date of the study. The intent of the TPL standard should be that entities must study and plan for inadequacies found in the studies. A one- or two-month lead time is not adequate to address any problems identified. Year One should be the year containing the first peak 12 months or more from the current date. Otherwise, TPL studies become merely seasonal operational studies, not planning studies. Alternative Language: "For the Planning Assessment started in a given year, Year One should contain the first system peak that occurs twelve months or more after the date

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 2 Comment
		of the Planning Assessment."
US Bureau of Reclamation	No	The language implies a requirement. The language "Year One must include the forecasted peak Load period for one of the following two calendar years" is a requirement and not a statement of clarification. If the definition is that "Year One" can also be the period used for forecast peak load, then it should be stated so. It is suggested that either the language in the definition is modified or the language is deleted from the definition and moved to the body of the standard.
United Illuminating	No	Year One should be used within the text of the requirement. Do not have a definition for Year One.
National Grid	No	Year One should be used within the text of the requirement. Do not have a definition for Year One. Year two could be deleted and R.2.1.1 modified as follows: For the Planning Assessment started in a given calendar year, the first year that is studied must include the forecasted peak Load period for one of the following two calendar years. An additional Near-term study must be performed that is four calendar years beyond the first year that is studied.
Tri-State Generation & Transmission	No	Comments: The Year One definition is somewhat clearer now, but there is still some ambiguity. We recommend the removal of the term "Year One, year two, and year five" from R2.1.1. and deletion of the Year One definition (definitions are not required for year two and year five, for instance). The Year One concept can be integrated into the definition of Near-Term Transmission Planning Horizon, which we suggest changing to "The period beginning with the first year following the operating horizon, as determined by the Transmission Planner or Planning Coordinator, through the fifth year." Then, rather than say "Year One, year two, and year five", we can use the phrase "at least one of the first two years of the Near-Term Transmission Planning Horizon, and the fifth year". This will require corresponding changes in R2.1.1 and R2.1.2.
Lakeland Electric	No	While the definition of Year One addresses the time span this year occupies, it does not address when that time span begins. The example which was added to the definition suggests that Year One begins twelve months from the start of the Planning Assessment, but it does not appear to be specifically stated. The following language is recommended: "The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing, beginning twelve months from the planned completion date of the Planning Assessment."
Northeast Utilities Consolidated Edison Co. of New York, Inc.	No	NU does not support the revised definition of Year One as we believe it leads to confusion. Our suggestion is that Year One should be the Peak Load Year after the study is initiated. The subsequent years should be counted from Year One (e.g., a study that is started in year 2010 with peak load in 2011 will have Year One as

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 2 Comment
		2011 and Year Two as 2012, etc.).
Modesto Irrigation District	No	The definition as it is in the current standards is fine. The new proposed definition is unclear.
NBSO	No	To avoid confusion, the formal definition for Year One should be eliminated and wording used to describe Year One be placed within the appropriate requirement. For example, R2.1.1 could be re-written to state: System peak Load representing a point in time 12-24 months and another point in time 48-65 months into the future from the time the study is initiated.
Central Maine Power Company New York State Electric & Gas Corp New York Independent System Operator	No	The added clarification to the definition of Year One serves to remove most ambiguity with respect to Year One. However, the revision has added further ambiguity to the terms “year two” and “year five” which are not defined. For the Planning Assessment started in a given calendar year, the first year that is studied must include the forecasted peak Load period for one of the following two calendar years. An additional Near-term study must be performed that is four calendar years beyond the first year that is studied. We recommend defining Year Five as the twelve month period 4 to 6 calendar years from the date of the Planning Assessment. We further recommend revising R2.1.1 as follows: “System peak Load for Year One and for Year Five.”Alternatively, the definition of Year One could be eliminated and described within the text of the requirements.
Tucson Electric Power Company	No	A seasonal reference should be included in the example. Alternative language beginning with the second sentence: For the Planning Assessment started in a given calendar year, Year One must include the forecasted peak load period for the forecasted peak load season that is between 12 and 24 months into the future from the current season. For example, if a Planning Assessment was started in 2011 prior to the forecasted peak season, then Year One must include the forecasted peak load for 2012. If the Planning Assessment was started in 2011 during or after the forecasted peak season, then Year One must include the forecasted peak load for 2013.
GDS Associates, Inc.	No	The definition it seem both incomplete and exhaustive:- If taken out of the planning assessment context, the definition is missing the matter that is supposed to identify. We suggest changing the first sentence such as “The first twelve month period to which the functional entity is responsible for the assessment of Transmission System Planning performance.”- While it will be a burdensome task to define each year that follows Year One, the definition of Year One may include a sentence that define the rule for the following years such as “All of the twelve months period following Year One shall commence immediately after the end of the preceding twelve months period.”- The definition should not include examples.
Pacific Gas and Electric Company		We recognize that the drafting team made changes to the definition of Year One based on industry comments. However, we believe that the revised language could allow for a situation where an entity could use its next season’s operating study as its Year One planning study. For example, if the entity does its study in the fall of

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 2 Comment
		2011, the proposed definition would allow the entity to use its summer 2012 operating study as its Year One study. This is a very short period to address any issued identified. Suggest working into the requirement that Planning Studies must look out at least 12 months beyond when the study is performed. This would still allow for the provision in the current definition example (“if a Planning Assessment was started in 2011, then Year One must include the forecasted peak Load period for either 2012 or 2013) because the entity would be able to use their 2013 Load period, but it would prevent the entity from using the 2012 Load period if they started the assessment late in 2011.
NERC staff	Yes	NERC staff supports the revisions to the definition of Year One. However, we believe an associated change should be made where this term is used in part 2.1.1 of Requirement 2 which requires modeling of “System peak Load for either Year One or year two, and for year five.” It seems the new definition of Year One would negate the need to refer to year two. NERC staff recommends that part 2.1.1 be changed to “System peak Load for Year One and for year five.”
Western Area Power Administration	Yes	Yes, this clarification helps. The drafting team could also define “year five”.
FirstEnergy	Yes	The change in the Year One definition provides greater flexibility for the industry and also addresses a prior FE comment during the 1st ballot. We appreciate the team’s careful consideration of the industry feedback and support the change.
TVA Transmission Planning & Compliance	Yes	TVA supports the change in the Year One definition - but would suggest that the word “started” should be changed to “completed” since a Planning Assessment may be started in one calendar year and finished in the next calendar year.

3.

The SDT has revised the Requirements language based on industry comments to the initial ballot. Do you support these changes? If you do not support these changes, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

Due to various industry comments, the SDT made the following clarifying change to Requirement R1:

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use ~~the latest~~-data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes PO as the normal ~~s~~System condition in Table 1.

The SDT believes that 6 months is the correct number in Requirement R1, Part 1.1.2 because the planner is evaluating longer term periods, and shorter duration outages, which have scheduling flexibility, are addressed by Operations Planning. Outages six months or longer will typically be over the study periods (peak and Off-Peak) addressed in Requirement R2, Part 2.1.3.

Requirement R1, Part 1.1.6 – An issue was raised that resources could be used for export to other areas. The SDT did not make a change to the requirement since exports to other areas are covered in Requirement R1, Part 1.1.5.

The majority of respondents agree with the posted changes to these requirements and no other changes have been made based on stakeholder comments.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 3 Comment
NERC staff	No	NERC staff suggests that the added sentence in R1 be deleted and “Normal System” in Table 1 be replaced with “No unplanned Element outages.” We have a problem with R1 establishing “normal system condition.” “Normal” is not defined, but the system condition that most people would define as “normal” is the System operating within its limits. There are no checks required on the projected system conditions to guarantee “operation within limits.” Staff realizes that if this were the case, the categories tested would all pass their respective tests. (In other words, the category tests may define operating limits that in turn define “normal” from a planning perspective.) Thus, the added sentence in R1 should be deleted. In Table 1, the use of the term “Normal System” in the column “Initial System Condition” really means “No unplanned Element outages.” All Elements that do not have a planned outage are assumed in-service (for transmission Elements) or available for dispatch (for generators).

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 3 Comment
		Contrast the term “Normal System” with categories P3 and P6, which have the loss of an Element (which is unplanned) followed by the loss of a second Element (also unplanned). “Normal System” should be replaced with “No unplanned Element outages.”
SERC Planning Standards Subcommittee Southern Company Ameren	No	The definition does not adequately address normal (pre-contingency) operating procedures or system configurations. Language should be added to the requirement (perhaps as R1.1.7) to include normal operating procedures or system configurations in place prior to any contingency occurring.
Bonneville Power Administration	No	Please clarify R1.1.2 to state “Known outage(s) of generation or Transmission Facility(ies) during the Planning Horizon with a duration of of at least six months.”
E.ON U.S.	No	In the statement: “the Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.”E.ON U.S. believes that the use of the pronoun “their” in the quoted section above is confusing. “Their” could be read as applying to the adjacent Planning Coordinators and not to the Planning Coordinator to whom the standard applies. E.ON U.S. recommends that the word “their” should be changed to “the Planning Coordinator’s and Transmission Planner’s” in order to make it clear.
Florida Reliability Coordinating Council, Inc - Transmission Working Group	No	No, Since “the latest” data may become available after the study is complete, a planner may not be able to ever complete a study. Please consider removing “the latest” from the second sentence.
Western Area Power Administration	No	It’s difficult to tell whether Requirement R1 is intended to require only one base case or whether it was intended to require creation of separate models for each possible N-0 condition (“normal system condition”) under a variety of stressing scenarios. The inserted language does not seem to provide additional clarity. Suggested language may be “This establishes the initial ‘Normal System’ condition corresponding to category P0 in Table 1.” Also, in Requirement R1.1.5, how are the Firm Transmission Service commitments supposed to be modeled in Power Flow Cases? Are they just to be modeled as loads, generation, and control area interchanges? Suppose a POR or POD is not at a generator or load bus. What selection of generation and load would represent the projected system conditions for this Firm Transmission Service commitment?
CenterPoint Energy	No	The SDT did not incorporate CenterPoint Energy’s previous comment regarding R1; therefore, CenterPoint Energy’s concerns remain.

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 3 Comment
United Illuminating National Grid Central Maine Power Company New York State Electric & Gas Corp	No	For R1 Ambiguity regarding base case assumptions, in combination with lack of clarity and clear direction of purpose regarding the sensitivity analysis, undermines the objectives of the standard; R1.1 Part 1.1.2. With respect to known outages, there needs to be greater flexibility in the standards (e.g. more tolerance to non-consequential load shedding or limitations to the contingencies that need to be considered (e.g. P0, P1, & P2)). Regional allowances for load shedding under this condition should be approved. Duration of known outages should be increased from six months to one year; R1.1 Part 1.1.6 Delete "required for Load". Resources may also be used for export to other areas, not just internal load.
ISO New England Inc.	No	R1.1 Part 1.1.2. With respect to known outages, there needs to be greater flexibility in the standards (e.g. more tolerance to non-consequential load shedding or limitations to the contingencies that need to be considered (e.g. P0, P1, & P2)). Regional allowances for load shedding under this condition should be approved. Duration of known outages should be increased from six months to one year; R1.1 Part 1.1.6 Delete "required for Load". Resources may also be used for export to other areas, not just internal load.
American Transmission Company	No	We propose the following changes and questions: R1 - We offer the minor suggestion of replacing the wording of "maintain System models within their respective areas" with "maintain System models of elements that are interconnected to any portion of the BES that is owned or operated by the TP or PC". This wording would avoid the ambiguity that can occur when a BA that is associated primarily with one TP declares ownership of a bus in another TP's geographic area, but expects its primary TP to maintain the BA's model data for the remote generation or load. R1.1.2 - We request a SDT opinion on how two individual outages should be modeled if they are both in excess of six months duration and they overlap by less than six months. Should the overlapping condition only be modeled if the condition is expected to last more than six months?
Tri-State Generation & Transmission	No	We suggest changing the added sentence to "This establishes the Category P0, No Contingency, Initial System Conditions in Table 1."
Lakeland Electric	No	Consider removing "...the latest..." from R1 and changing R1.1.2 to state "...six months during the period of

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 3 Comment
		study.”
Northeast Utilities	No	<p>NU believes that the Normal System Conditions as stated in Requirement R1 should establish the base case conditions to be used for the assessment studies. More guidelines for developing base cases should be addressed in the requirements. What the statement in Requirement R1 lacks is the manner of creating generation dispatches and the level of interface flows (level of stress), which are central to any base case to be used to assess the reliability of the electric power network. Depending upon how the base case dispatches and the level of interface flows are created, a study may reveal reliability violations in the power system. This is a weakness of the existing TPL standards. NU, however, will support the idea of developing regional guidelines in regard to the nature of the base cases to be used for the NERC reliability studies.</p> <p>Comment on Requirement R1.1, Part 1.1.2: With respect to known outages NU requests that the six month duration listed by the requirement should be changed to one year duration.</p> <p>Requirement R1.1 Part 1.1.6: The phrase "required for Load" should be deleted as this confuses the issue [since resources may also be used for export to other areas and not just internal load].</p>
NBSO	No	R1 should have some language to state that base case assumptions should be made such that they appropriately stress the system to be tested and are in accordance with good engineering practice.
Tucson Electric Power Company	No	<p>Proposed changes 1.1.1 Existing Facilities that will not be changed before the study year</p> <p>1.1.3 New planned Facilities and planned changes to existing facilities</p>
GDS Associates, Inc.	No	The Time Horizon should be for both Near-Term and Long-Term Planning.
MidAmerican Energy	No	There are concerns over the FERC outstanding March order on TPL and how FERC interprets “normal” or base case conditions and “assuming” an entities primary protection system is out of service and must rely on its backup protection system to operate. This concept combined with the new tables cannot be perpetuated.
Xcel Energy	No	<p>Although we support the change conceptually, we believe the sentence added in R1 needs more specificity to ensure a better correlation to the relevant portions of Table 1. Please make it clear that the system model created as per R1 corresponds to Category P0 by explicitly referring to it.</p> <p>Suggested language is: ‘This establishes the “Normal System” initial condition corresponding to category P0 in Table 1.’ Further, consider omitting the word “System” in Table 1 Column 2 heading by calling it “Initial Condition” – the redundancy produced by its usage in both heading and entry does not appear to provide any</p>

Organization	Yes or No	Question 3 Comment
		<p>value.</p> <p>Alternative suggested language is: ‘This establishes the “Normal” initial system condition corresponding to category P0 in Table 1.’ This alternative approach envisages changing the Column 2 entries to “Normal” since the word “System” is now retained in the heading.</p>
MRO's NERC Standards Review Subcommittee	Yes	<p>We propose the following changes and questions:R1 - We offer the minor suggestion of replacing the wording of “maintain System models within their respective areas” with “maintain System models of elements that are interconnected to any portion of the BES that is owned or operated by the TP or PC”. 3.1 Requirement R2 and Part 2.1 – past studies

Summary Consideration:

The majority of respondents agree with the changes to these requirements and only the changes to these requirements noted below have been made.

The SDT believes that the supposed inconsistencies mentioned in the language are not inconsistencies at all but necessary qualifiers. No change made.

Based on comments received, the SDT has modified Requirement R2, part 2.6.2 as follows to provide additional clarity:

2.6.2 For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. ~~shall not include any material changes unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area.~~ Documentation to support the technical rationale for determining material changes shall be included.

The following change was made to clarify that the list following the statement is not all inclusive:

2.7.1 List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions may include:

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered them. In some of the cases relating to the above comments, the SDT has already responded to similar comments and those responses are quoted here for convenience:

2.1.5 – “When a piece of long lead-time Equipment is unavailable, System adjustments will need to be made. The System, after it is adjusted to accommodate that piece of Equipment out of service will be treated as the “normal” (PO) condition in Table 1 and the rest of Table 1 will be applied as stated. This requirement is intended for the Planning Coordinator and/or Transmission Planner to take into account their spare equipment strategy for long lead time Equipment when assessing the performance of their System. If the loss of a piece of major Equipment can be replaced within a reasonable period of time, planning studies for the following year can assume that that piece of Equipment will be replaced. If not, its impact of unavailability would need to be assessed. Actions such as out of merit dispatch, operational restrictions, System reconfiguration can be part of a Corrective Action Plan if the System cannot meet performance requirements without the Facility in service.”

Organization	Yes or No	Question 4 Comment
<p>Northeast Power Coordinating Council Consolidated Edison Co. of New York, Inc.</p>	<p>No</p>	<p>The revisions made to Requirement R2 Part 2.1 appear to resolve the concern that past studies could not be used to comply with the short-term steady state study requirements. This revision must be carried through to other sections (R2.2, 2.2.1). However, the language of Requirement R2 Part 2.2 still seems to suggest that current annual studies are always required for the long-term steady state assessment to be compliant. This may have been an oversight, for consistency Requirement R2 Part 2.2 should be modified to similarly read as Requirement R2, Part 2.1.</p> <p>Regarding R2.2, the language should be consistent with 2.1. For example, use "current or qualified past studies" instead of "the following annual current study".</p> <p>Revisions made to Requirement R2.1.5 have made it worse than was originally drafted. This would require the PC & TP to study (meaning performing a technical analysis) of the impact and probability of the possible unavailability of any piece of equipment with a lead time of one year or more. Such an evaluation of spare equipment strategies would require significant additional resources and data, but provide no benefit to system reliability, as it is redundant to the existing N-1-1 contingency requirement (P6).</p> <p>R2.7 requires that Corrective Action Plans are included in each Planning Assessment and states "Such actions may include..." followed by a list of actions. Restricting allowable actions, and excluding runback/tripping of HVDC would have a direct impact on multiple existing facilities in New York and would adversely impact the reliability planning of the NYCA. Runback/tripping of HVDC must be added to the list, and also suggest revising to "Such actions may include but not be limited to:".</p>
<p>Florida Reliability Coordinating Council, Inc - Transmission Working Group</p>	<p>No</p>	<p>No, Please consider removing R.2.6.2. The overwhelming majority of PAs use a 10 year set of planning models developed annually by Regions or Subregions. These annual sets of planning models will always have some changes. The annual study requirement is especially problematic for Stability and Short circuit studies that require much more engineering time to complete and are much less likely to have results impacted by minor model changes such as different load forecasts. Uncertainty with audit review of technical rationale documentation will serve to focus Transmission Planning engineering resources on short term compliance to an extent that is counter productive.</p>
<p>Western Area Power Administration</p>	<p>No</p>	<p>R 2.1.5: The issue in this Requirement is studied in the Operations next-day; next-week; next-month studies required under the TOP Standards; and are also covered by processes such as the Operational Transfer Capability Policy Committee (OTCPC) seasonal study process within the WECC. It would be quite onerous to run a complete power flow simulation on separate base cases for each transformer (or other equipment with long lead time) initially out of service. The revision in language from "Planning Assessment" to "studies" does not clarify that a power flow simulation is not necessarily required for each situation. A valid assessment could include other methods such as using sound technical reasoning to relate the initial out-of-service</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 4 Comment
		<p>condition to a condition that has already been studied. This condition may have taken place in previous operational studies. The language in the standard could be improved to make this clarification - perhaps reference R2.6. Additionally, this Requirement still needs further clarification. Currently the scope of equipment applicable to the requirement could be misinterpreted as larger than that contemplated by FERC. The standard as written seems to say that the responsible entity needs to study the spare equipment strategy for all "major transmission equipment" with long lead times. In the directive to include this requirement, FERC used the term "critical facilities". In the NOPR to Order No. 693 they stated, "Critical facilities are those facilities that impact IROLs and deliverability of generation to firm load" (P1081). In Order No. 693 FERC also said, "if an entity's spare equipment strategy for the permanent loss of a transformer is to use a 'hot spare' or to relocate a transformer from another location in a timely manner, the outage of the transformer need not be assessed under peak system conditions" (P1725). Finally, the drafting team could clarify if this requirement applies to radial branches (such as generator step-ups or step-down to load). Such branches may be construed as "critical facilities" but the impediment to deliverability of generation to firm load is consequential to the initial outage.</p>
Lakeland Electric	No	Please consider removing R.2.6.2
Platte River Power Authority	No	<p>I like that you have requirements for qualifying past studies, but Part 2.6.2 is confusing. Please change Part 2.6.2 to read something like: "For steady state, short circuit or Stability analysis: no material changes have occurred to the System represented in the study or, if material changes have occurred, a technical rationale can be provided to explain that the changes do not impact the performance results in the study area."</p>
Orlando Utilities Commission	No	<p>Allowing the use of past studies in lieu of new studies for part or all of an assessment when the underlying system hasn't changed in a significant change if very prudent. However the wording in 2.6.2 of "unless a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area" is of concern. By this wording is it intended that the planner must demonstrate that every material change has no impact? In essence doing more work to prove that a study isn't required then the study would take? Or that the planner must essentially have a technical rationale (overarching) for determining when a material change is "material enough" to impact system performance?</p>
Minnesota Power	No	<p>Requirement 2 - This requirement states that Stability analyses be performed as part of the annual Planning Assessments. Minnesota Power would like to see the term "Stability analysis" more clearly defined as there are several different types of stability related analysis that can be performed for power systems including: transient stability, voltage stability and small signal stability.</p>
US Bureau of Reclamation	No	The question is misleading in that R2 also include current studies. The overall structure of the standard

Organization	Yes or No	Question 4 Comment
		<p>could be greatly improved if the standard were segmented into Near Term and Long Term with sub segments for each specific type of analysis to be performed.</p> <p>Second, the standard does not use consistent terms. The Planning Assessment is to include Near Term and Long Term portions which must have steady state analysis, short circuit analysis, and stability analysis (ref. R2). Requirement R 2.1 introduces sensitivity analysis for the Near Term portion, and then refers to the Planning Analysis which is in reality both Near Term and Long Term portions. That implies that sensitivity analysis must be required for both? The standard repeats the requirement for annual stability studies in 2.4 which was already a requirement for Planning Assessments.</p> <p>The requirement 2.1.5 is one the most problematic requirements in this standard. This requirement implies that an entity must have spare equipment and a strategy to employ it. That is beyond the scope of the Energy Policy Act 2005. Spare equipment is not on-line and does not contribute to the reliability of the existing system. The Energy Policy Act of 2005 specifically prohibits the requirement to enhance or modify the system. The use, application, or requirement to have spare equipment violates that prohibition. This section should be removed. In addition, this requirement suffers from an ability to implement. In the first case, the requirement is invoked if the spare equipment strategy could result in unavailability of transmission equipment. How is that determined? There is no nexus to that determination. The unavailability may have already occurred once the transmission equipment has failed. The only way to avoid unavailability if the transmission equipment that fails has a hot stand-by with automatic fail-over. The presence or not of a suitable replacement will still result in unavailability by virtue of the failure o the first piece of transmission equipment. Next problem, who will second guess the owner of the replacement. Where is the requirement to make the replacement strategy available? The standard should focus on system performance with existing equipment to meet current and future loads.</p>
CenterPoint Energy	No	The SDT did not incorporate CenterPoint Energy's previous comments regarding R2; therefore, CenterPoint Energy's concerns remain.
ISO New England Inc. United Illuminating National Grid	No	We can agree with R2.1 however with respect to R2.2 Language should be consistent with 2.1 for example - use "current or qualified past studies" instead of "the following annual current study."
Northeast Utilities	No	The revisions made to Requirement R2 Part 2.1 appear to resolve the concern that past studies could not be used to comply with the short-term steady state study requirements. However, the language of Requirement R2 Part 2.2 still seems to suggest that current annual studies are always required for the long-term steady state assessment to be compliant. This may have been an oversight, for consistency Requirement R2 Part

Organization	Yes or No	Question 4 Comment
		2.2 should be modified to similarly read as Requirement R2, Part 2.1.
Hydro-Quebec TransEnergie	No	Requirement R2 Part 2.2 should be modified to read as 2.1 (not impose current annual studies as the only requirement for assessment)
American Transmission Company	No	R2.1.3 - We offer the minor suggestion of revising R2.1.3 to state, “Known outages of generation or Transmission Facilities with a duration of at least six months be simulated along with P1 events for the System peak or Off-Peak conditions when the outages are scheduled to occur.” We interpret that the requirement should only call for the simulation of individual outages with duration of six months or more and not imply the simulation of sequential (back-to-back) outages where each individual outage is less than six months, but the composite duration of the back-to-back outages is more than six months. We also interpret that if two or more known outages with duration of at least six months are overlapping, then the overlapping outage condition would only be simulated for the conditions when the overlapping outages are scheduled to occur if the duration of the overlapping condition is at least six months.
Tri-State Generation & Transmission	No	2.1.5 - Change “shall be performed for” to “shall have been performed for.”
Lakeland Electric	No	No, the phrase any material changes used in requirement R.2.6.2 will effectively cause all Planning Authorities to run all studies every year regardless of minor changes in the model. The overwhelming majority of PAs use a 10 year set of planning models developed annually by Regions or Subregions. These annual sets of planning models will always have some changes. The annual study requirement is especially problematic for Stability and Short circuit studies that require much more engineering time to complete and are much less likely to have results impacted by minor model changes such as different load forecasts. Uncertainty with audit review of technical rationale documentation will serve to focus Transmission Planning engineering resources on short term compliance to an extent that is counter productive. Please consider removing R.2.6.2
NBSO	No	NBSO agrees with the language for R2.1, but the language with R2.2 should be changed to be consistent with R2.1. NBSO disagrees with the revisions to R2.1.5. Requiring PAs to study instead of assess the possible unavailability of equipment with a lead time of a year or more will result in significant demand on resources with little impact on system reliability. NBSO also questions what additional value such studies will bring in addition to the N-1-1 requirements (P6).

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 4 Comment
Central Maine Power Company New York State Electric & Gas Corp	No	<p>We completely agree with the revision to R2.1, but this revision must be carried through to other sections (R2.2, 2.2.1) and R2.2 language should be consistent with 2.1 for example - use "current or qualified past studies" instead of "the following annual current study".</p> <p>Revisions made to Requirement R2.1.5 have made it worse than as originally drafted. This would require the PC & TP to study, or in other words perform technical analysis of, the impact and probability of the possible unavailability of any piece of equipment with a lead time of one year or more. Such an evaluation of spare equipment strategies would require significant additional resources and data, but provide no benefit to system reliability, as it is redundant to the existing N-1-1 contingency requirement (P6).</p>
Progress Energy	No	<p>While PE does not disagree with the basic premise of 2.1, PE disagrees with the language to the extent that 2.1 is qualified by language in 2.6 and 2.6.2. The issue of managing modeling of case data is already adequately handled in MOD Standards. Furthermore, PE does not feel that the term “material” can be defined with any mutually agreed-upon boundaries, and could be construed to require any and all Transmission Planners and/or Planning Authorities to make multiple revisions of base cases each year. PE therefore appeals to the SDT to remove the language referring to R2 Part 2.6.2 and furthermore appeals for the deletion of R2.6.2.</p> <p>Furthermore, PE appeals to the SDT to modify R2.6.1 to say “For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate the validity of the results of any studies older than five years or any studies using cases containing major modeling differences from other submitted studies.”</p>
ERCOT ISO	No	<p>Previous Comment unaddressed: Requirement 2.1.5: Including the spare equipment strategy will be difficult for a PC that doesn’t own or manage the transmission equipment or the strategies. This requirement should only be applicable to TP.</p> <p>Furthermore, R7 should be deleted and the responsibilities of each entity should be explicitly stated within the specific requirements.</p>
New York Independent System Operator	No	<p>NYISO completely agrees with the revision to R2.1, but this revision must be carried through to other sections (R2.2, 2.2.1).</p> <p>Revisions made to Requirement R2.1.5 have made it worse than as originally drafted. This would require the PC & TP to study, or in other words perform technical analysis of, the impact and probability of the possible unavailability of any piece of equipment with a lead time of one year or more. Such an evaluation of spare equipment strategies would require significant additional resources and data, but provide no benefit to system reliability, as it is redundant to the existing N-1-1 contingency requirement (P6).</p>

Organization	Yes or No	Question 4 Comment
		<p>R2.7 requires that Corrective Action Plans are included in each Planning Assessment and states “Such actions may include...” followed by a list of actions. Restricting allowable actions, and excluding runback/tripping of HVDC would have a direct impact on multiple existing facilities in New York and would adversely impact the reliability planning of the NYCA. Runback/tripping of HVDC must be added to the list.</p>
Xcel Energy	No	<p>Specifically, the phrase “as follows” at the end of Part 2.1 does not appear to be an appropriate lead-in for the sub-parts under 2.1. Please consider re-wording Part 2.1 consistent with Part 2.4 to use the lead-in “The following studies are required:”</p> <p>Why is it essential to use the qualifier “annual” for “current studies” in Part 2.1? Can a study be considered current if it is conducted less frequently than once every year? Note that Parts 2.3, 2.4 and 2.5 do not use the “annual” qualifier, nor does Requirement R2. Recommend deleting this apparently non-essential qualifier in both 2.1 and 2.2 to improve consistency.</p> <p>In Part 2.5, should “annually” be inserted after “shall be assessed” to make it consistent with Parts 2.1, 2.2, 2.3 and 2.4? If the omission is intentional in 2.5, please explain why.</p> <p>To improve semantics and consistency, please modify 2.2.1 as follows to make it consistent with 2.1.1 and 2.4.1 “System peak Load for one of the years in the...”</p> <p>We are unable to appreciate why the wording in Part 2.3 is not consistent with that in Part 2.1, 2.2, 2.4 or 2.5. Note that the semantics of the wording “... (steady state / stability) analysis shall be assessed annually...” can be interpreted to be much different than the semantics of the Part 2.3 wording “The short circuit analysis.... shall be conducted annually ...”. The former requires the analysis to be *assessed* annually but 2.3 requires the analysis to be *conducted* annually without explicitly requiring it be assessed — is the usage of “conducted” instead of ‘assessed” consistent with the intent?</p> <p>It is unclear why the stipulation to use “current or qualified past studies“ needs to be repeated in each of the Parts 2.1, 2.2, 2.3, 2.4 and 2.5 when it is already specified in Requirement R2 at the highest hierarchy level. Suggest eliminating redundant usage by deleting from the parts under R2.</p> <p>In Part 2.6.2, the intent is awkwardly conveyed within the phrase “...the System represented in the study shall not include any material changes unless...”. In the context of a *past* study, how can the System represented possibly include any material changes (that would have presumably occurred after the study)? Suggest modifying Part 2.6.2 to read “For steady state, short circuit or Stability analysis: no material changes have occurred in the System represented in the study or, if material changes have occurred, a technical rationale shall be provided to explain why they do not significantly impact the study results.”</p> <p>In Parts 2.6.1 and 2.6.2, the lead-in phrase “For steady state, short circuit or Stability analysis:” does not appear to be essential. Even in the absence of this phrase, wouldn’t these two attributes of a qualified past study apply (by default) to all types of analysis? Suggest deleting this seemingly redundant phrase in both 2.6.1 and 2.6.2.</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 4 Comment
		<p>Perhaps this comment is more persuasive when considered together with the next comment.</p> <p>Recommend moving Part 2.6 to the first part under R2 (Part 2.1) because it defines the qualified past studies which are applicable to all types of analysis (steady state, stability and short circuit) that are detailed in the subsequent parts.</p>
MRO's NERC Standards Review Subcommittee	Yes	<p>R2.1.3 - We offer the minor suggestion of revising R2.1.3 to state, "Known outages of generation or Transmission Facilities with a duration of at least six months be simulated along with P1 events for the System peak or Off-Peak conditions when the outages are scheduled to occur." We interpret that the requirement should only call for the simulation of individual outages with duration of six months or more and not imply the simulation of sequential (back-to-back) outages where each individual outage is less than six months, but the composite duration of the back-to-back outages is more than six months. We also interpret that if two or more known outages with duration of at least six months are overlapping, then the overlapping outage condition would only be simulated for the conditions when the overlapping outages are scheduled to occur if the duration of the overlapping condition is at least six months.</p> <p>R2.1.5 - We offer a major suggestion regarding the phrase "could result in the unavailability of major transmission equipment" because this phrase is ambiguous and not defined. So, there is a significant risk of different and possibly contradictory interpretations by TPs, PCs, and auditors. We proposed adding that the TP and PC "shall provide documentation to support the technical rationale for defining unavailability of major transmission equipment" similar to R2.5.</p>
NERC staff	Yes	NERC staff supports the use of qualified past studies for the Near Term horizon.
American Electric Power (AEP)	Yes	R2, Part 2.1 - idicates that 'qualified' past studies can be utilized. This is an ambiguous term and we suggest the SDT consider the implications.

3.2 Requirement R2, Parts 2.1.4 & 2.4.3 – sensitivity analysis:

Summary Consideration:

The SDT intent is that multiple condition sensitivities will be assessed since you are required to run the cases for peak and Off-peak conditions, multiple years, etc. If the problem exists in two or more of these cases, it would be an indication of ‘multiple’ problems. No change made.

The SDT understands that running sensitivities may require additional work for some entities. The sensitivities studied should be used to compare system response to different conditions to provide a broader perspective for the planner and the SDT believes that this is important enough to justify the additional work.

The SDT has made a clarifying change to the words in Requirement R2, part 2.1.4 based on comments received:

2.1.4 For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response performance:

The SDT has made the language in Requirement R2, part 2.7, bullet 7 consistent with the other parts of the standard as follows:

- List System deficiencies and the associated actions needed to achieve required System performance. Examples of Ssuch actions may include:

The majority of respondents agree with the changes to these requirements and only the changes to the requirements noted above have been made in response to stakeholder comments.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 5 Comment
Northeast Power Coordinating Council Consolidated Edison Co. of New York, Inc.	No	Part 2.1.4, requires an entity to vary one or more conditions to demonstrate a change in performance. If the cases were initially stressed, this may force an entity to simulate conditions with less severe stresses. At this point, there is limited to no value to this additional workload. Having a requirement to test at least one sensitivity as a blanket requirement may not be informative by itself and is more unclear since sensitivities are being required on an undefined base set of conditions. If an entity does a case with a stressed set of assumptions, is it

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 5 Comment
		<p>necessary to do a non-stressed case? Additionally, our concern involves wording under 2.1.4 and 2.4.3 that sensitivities are required varying one or more conditions. Subsequently, in requirement 2.7.2 corrective action plans need to be developed to resolve performance deficiencies “only” if identified in multiple conditions or require a rationalization why no corrective action plan is necessary. Multiple conditions sensitivities under 2.1.4 and 2.4.3 are necessary to satisfy requirement 2.7.2.</p> <p>Requirement 2.7.2 adds ambiguity and should be removed. If not, a suggested revision to Requirement 2.7.2 as follows:2.7.2. Corrective Action Plans are not required for performance deficiencies identified in a sensitivity analysis. In general, the scope of this requirement is too broad and non-specific, and only results in undue study burden. Is it necessary for sensitivity analysis to be included in requirements since in accordance with good engineering practices a conservative approach should be used in studies? The standard is referring to requirements for sensitivity and other issues without a reference to base assumptions as commented in issue #3. The standard must describe base assumptions. To define a sensitivity condition, NERC must define base assumptions.</p>
Hydro One Networks Inc.	No	The scope of this requirement is too broad and non-specific and only results in undue study burden.
MRO's NERC Standards Review Subcommittee	No	<p>R2.1.4 & R2.4.3 - We offer a major suggestion regarding the terms of ‘credible’ and ‘measurable change’ because these terms are ambiguous and not defined. So, there is a significant risk of different and possibly contradictory interpretations by TPs, PCs, and auditors. We proposed adding that the TP and PC “shall provide documentation to support the technical rationale for determining the range of credible conditions and measurable change in performance” similar to R2.5.</p> <p>R2.1.4 & R2.4.3 bullet items - We offer the minor suggestion that the number and description of the bullet items in R2.1.4 match the bullet points in R2.4.3. Otherwise, please explain the reasons for any differences between the bullet items in R2.1.4 and R2.4.3.</p> <p>R2.1.4 bullet #2 & # 5 - We suggest that the wording in bullet #2 be changed to “Expected transfers and other generation dispatch scenarios”. This modification would put the transfer and dispatch element, which are complementary, together in the same bullet item, rather than grouping the ‘generation dispatch’ (operating level) element together with the generation capacity elements in bullet item #5.</p> <p>R2.1.4 bullet #7 - We offer the minor suggestion that the term “planned” be replaced with “known” to be consistent with R1.1.2 and R2.1.3. Besides the term “planned outage” has a specific meaning in the Reliability Standards that are specific to the Operating horizon.</p> <p>R2.7.2 - With regard to "include actions to resolve performance deficiencies identified in multiple sensitivity</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 5 Comment
		studies", we do not think that mitigation plans should be required for deficiencies found in multiple sensitivity studies because the conditions in some sensitivity studies are more extreme and less likely than base case conditions. It's impractical to require corrective actions for longer term horizon sensitivities due to how fast the electric grid changes. We believe sensitivity analyses are valuable to improving the development of mitigation plans to address base case performance limit concerns. Some of the sensitivity study conditions are not credible or plausible enough to warrant the implementation of mitigation measures. What is the interpretation of multiple sensitivity studies - more than one or a majority of the number that were studied?
IRC Standards Review Committee	No	The primary concern involves wording under 2.1.4 and 2.4.3 that sensitivities are required by varying one or more conditions. Subsequently, in requirement 2.7.2 corrective action plans need to be developed to resolve performance deficiencies "only" if identified in multiple conditions or require a rationalization why no corrective action plan is necessary. Multiple conditions sensitivities under 2.1.4 and 2.4.3 are necessary to satisfy requirement 2.7.2. Requirement 2.7.2 adds ambiguity and should be removed. Alternatively, Requirement 2.7.2 could be revised as follows: 2.7.2. Corrective Action Plans are not required for performance deficiencies identified in a sensitivity analysis. If a Planning Coordinator includes Corrective Action Plans to resolve performance deficiencies identified in multiple sensitivity analysis, the Planning Coordinator shall provide documentation to support those Plans.
Florida Reliability Coordinating Council, Inc - Transmission Working Group	No	This change does not clarify the required sensitivity analysis. A measureable change in performance is unclear? Instead of a measurable change in performance, a measurable change in contingency response of the Bulk Electric System would be more appropriate. A change in performance implies not meeting one of the performance requirements as specified in Table 1.
Lakeland Electric	No	A "measureable change in performance" can be interpreted as not meeting one of the performance requirements as specified in Table 1 in order for the condition to be selected as a sensitivity. This will cause utilities to perform sensitivity analysis for all system conditions listed in R2.1.4 to determine which one fails to meet one of the performance requirements in Table 1, as one may not be able to tell performance impact until after the studies are performed. Suggested change: "...one of the following conditions by a sufficient amount...system conditions that may demonstrate a measurable change in system response."
Orlando Utilities Commission	No	What is meant by "measurable change in performance"? Is this a measure that the sensitivity should move the system from meeting the performance requirements to not meeting the performance requirements? Or just a measurable change in system response, IE the loading was 45% on this corridor but is now 76%.
US Bureau of Reclamation	No	Sensitivity analysis is not included in R2. This gets back to the structure of the standard. There should a clear indication of the studies that are to be included in the Near-Term and Long-Term portions of the Planning

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 5 Comment
		Assessments.
CenterPoint Energy	No	The SDT did not incorporate CenterPoint Energy's previous comments regarding R2; therefore, CenterPoint Energy's concerns remain.
California ISO	No	Requirement 2.7.2 could be revised as follows:2.7.2. Corrective Action Plans are not required for performance deficiencies identified in a sensitivity analysis. If a Planning Coordinator includes Corrective Action Plans to resolve performance deficiencies identified in multiple sensitivity analysis, the Planning Coordinator shall provide documentation to support those Plans.
ISO New England Inc.	No	Part 2.1.4, requires an entity to vary one or more conditions to demonstrate a change in performance. If the cases were initially stressed, this may force an entity to simulate conditions with less severe stresses. At this point, there is limited to no value to this additional workload. Having a requirement to test at least one sensitivity as a blanket requirement may not be informative by itself and is more unclear since sensitivities are being required on an undefined base set of conditions Additionally, our concern involves wording under 2.1.4 and 2.4.3 that sensitivities are required varying one or more conditions. Subsequently, in requirement 2.7.2 corrective action plans need to be developed to resolve performance deficiencies “only” if identified in multiple conditions or require a rationalization why no corrective action plan is necessary. Multiple conditions sensitivities under 2.1.4 and 2.4.3 are necessary to satisfy requirement 2.7.2. Requirement 2.7.2 adds ambiguity and should be removed. Requirement 2.7.2 should be revised as follows:2.7.2. Corrective Action Plans are not required for performance deficiencies identified in a sensitivity analysis.
United Illuminating National Grid	No	If an entity does a stressed set of assumptions do they always need to do a non-stressed case?
Hydro-Quebec TransEnergie	No	It is questionable that sensitivity analysis be included in Requirements since a conservative approach should already be used in studies, in accordance with good engineering practices.
American Transmission Company	No	<p>R2.1.4 & R2.4.3 - We offer a major suggestion regarding the terms of ‘credible’ and ‘measurable change’ because these terms are ambiguous and not defined. So, there is a significant risk of different and possibly contradictory interpretations by TPs, PCs, and auditors. We proposed adding that the TP and PC “shall provide documentation to support the technical rationale for determining the range of credible conditions and measurable change in performance” similar to R2.5.</p> <p>R2.1.4 & R2.4.3 bullet items - We offer the minor suggestion that the number and description of the bullet items in R2.1.4 match the bullet points in R2.4.3. 		<p>the bullet items in R2.1.4 and R2.4.3.</p> <p>R2.1.4 bullet #7 - We offer the minor suggestion that the term “planned” be replaced with “known” to be consistent with R1.1.2 and R2.1.3. Besides the term “planned outage” has a specific meaning in the Reliability Standards that are specific to the Operating horizon.</p> <p>R2.7.2 - With regard to "include actions to resolve performance deficiencies identified in multiple sensitivity studies", we do not think that mitigation plans should be required for deficiencies found in multiple sensitivity studies because the conditions in sensitivity studies are more extreme and less likely than base case conditions. Some sensitivity study conditions are not credible or plausible enough to warrant the implementation of mitigation measures. What is the SDT interpretation of multiple studies - more than one or a majority of the sensitivities that were studied?</p>
Lakeland Electric	No	<p>It is recommended that the phrase “...measureable change in performance...” be changed to “...measurable change in system response...” A change in performance is unclear, and could suggest that a sensitivity study is valid only if the System is stressed to the point that it no longer performs within the criteria established by Table 1.</p> <p>In addition, it is recommended that the following text appear after the last sentence of 2.4.3: “The condition or conditions to be varied shall be left to the discretion of the Transmission Planner or Planning Coordinator, provided they are selected from the list below.”</p>
Northeast Utilities	No	<p>The standard is referring to requirements for sensitivity and other issues without a reference to base assumptions as commented in Question #3. The standard must describe base assumptions. To define a sensitivity condition, NERC must define base assumptions.</p>
Modesto Irrigation District	No	<p>This new requirement will expand the scope of the study work beyond a reasonable extent.</p>
NBSO	No	<p>Base case assumptions should be made such that they appropriately stress the system to be tested and are in accordance with good engineering practice. If the base cases are already stressed, the requirement to study sensitivity cases may result in the study of less severe conditions, and thus require additional time and resources while providing little additional value to the overall assessment.</p>
Central Maine Power Company New York State Electric & Gas	No	<p>These sensitivities need to be considered if not already included in the base case assumptions.</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 5 Comment
Corp		
Progress Energy	No	PE does not have concerns in general with either 2.1.4 or 2.4.3. PE does, however, disagree with the wording at the end of the main paragraph of 2.4.3. Whether or not analysis qualifies as sensitivity analysis should not be predicated upon the end results; rather, it should be based upon major case modeling differences. PE therefore recommends that the phrase "...that demonstrate a measurable change in performance" be removed so that the last sentence in the main paragraph read "...by a sufficient amount to stress the System within a range of credible conditions."
ERCOT ISO	No	The stress test requirements should be deleted. The purpose of this proposed Standard is to establish planning performance standards that support reliable operation. This is achieved by imposing performance requirements relative to specific conditions and contingencies. Compliance with the performance metrics within these boundaries is presumably indicative of a reliable system. It is unclear what value is added by stress testing the system in accordance with undefined, vague parameters, as required by Requirements 2.1.4 and 2.4.3. The criteria in the relevant requirements that govern the stress testing are defined by the following ambiguous phrase: 1) "by a sufficient amount"; 2) "range of credible conditions"; and 3) "measurable change of performance". Application of these criteria introduces uncertainty for both the regulated community and the relevant compliance enforcement authorities, which, in turn, creates audit risks for regulated entities. Furthermore, there is no reliability value because the stress test requirements do not establish objective criteria and do not prescribe any actions based on the stress test results. Reliability Standards should set specific obligations that are readily discernible and achievable on a consistent basis. The existing Standard does this by setting specific performance obligations relative to specific conditions and contingencies. Conversely, the stress test requirements introduce ambiguity and uncertainty with no reliability benefit; the only apparent effect is unnecessary audit liability risk for regulated entities. Accordingly, ERCOT believes that these requirements should be deleted.
Tucson Electric Power Company	No	TEP agrees with removing the phrase "not already included in the studies." However, TEP does not understand the purpose of sensitivity studies. TEP is concerned that imposing additional sensitivity studies could lead to requirements that exceed the proposed standards. TEP recommends removing sensitivity analysis from the standard.
New York Independent System Operator	No	Our concern involves wording under 2.1.4 and 2.4.3 that sensitivities are required varying one or more conditions. Subsequently, in requirement 2.7.2 corrective action plans need to be developed to resolve performance deficiencies "only" if identified in multiple conditions or require a rationalization why no corrective action plan is necessary. Multiple conditions sensitivities under 2.1.4 and 2.4.3 are necessary to satisfy requirement 2.7.2.

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 5 Comment
		Requirement 2.7.2 adds ambiguity and should be removed. Requirement 2.7.2 should be revised as follows:2.7.2. Corrective Action Plans are not required for performance deficiencies identified in a sensitivity analysis.
GDS Associates, Inc.	No	The requirements are extremely burdensome. We recommend changing the last sentence of 2.1.4 requirement by removing “by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:” because there are instances where listed conditions may not result in measurable changes in performance (Ex. An increase in load in a well built system may not cause any measurable changes in performance because there is sufficient transmission capacity to serve the load).
SMUD		What is the significance of changing the wording for section R2.1.5 from ‘assessed’ to ‘studied’ and ‘Planning Assessments’ to ‘studies’?
Western Area Power Administration	Yes	<p>In Requirement 2.1.4, "Sensitivity Analysis". How much change does it take in any of the modeling assumptions (load, generation, voltage support, topology, etc.) to significantly stress the system within a range of credible condition? As this Requirement relates to R2.7, Would it be necessary to have Corrective Action Plan(s) if needed to meet all the Sensitivity Cases? How many Sensitivities before must have Corrective Action Plan?</p> <p>Also - why is it essential to use the qualifier “annual” for “current studies” in Part 2.1? Can a study be considered current if it is conducted less frequently than once per year? Note that Parts 2.3, 2.4 and 2.5 do not use the “annual” qualifier, nor does Requirement R2. Recommend deleting this apparently non-essential qualifier in both R2.1 and R2.2.</p> <p>We are unable to appreciate why the wording in Part 2.3 is not consistent with that in Part 2.1, 2.2, 2.4 or 2.5. Note that the semantics of the wording “... (steady state / stability) analysis shall be assessed annually...” can be interpreted to be much different than the semantics of the Part 2.3 wording “The short circuit analysis.... shall be conducted annually ...”. The former requires the analysis to be *assessed* annually but 2.3 requires the analysis to be *conducted* annually without explicitly requiring it be assessed -- is the usage of “conducted” instead of ‘assessed’ consistent with the intent?</p> <p>In Part 2.6.2, the intent is awkwardly conveyed within the phrase “...the System represented in the study shall not include any material changes unless...”. In the context of a *past* study, how can the System represented possibly include any material changes (that would have presumably occurred after the study)? Suggest modifying Part 2.6.2 to read “For steady state, short circuit or Stability analysis: no material changes have occurred in the System represented in the study or, if material changes have occurred, a technical rationale shall be provided to explain why they do not significantly impact the study results.”</p>

3.3 Requirement R2, Part 2.4.1 – dynamic load models:

Summary Consideration:

The majority of respondents agree with the changes to these requirements and no changes to these requirements have been made in response to stakeholder comments.

The SDT does not intend that detailed dynamic Load models will be required for Loads in the System models used for the assessments. In particular, Requirement R2, part 2.4.1 states that an aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

The SDT has placed this requirement in TPL standards because it is not presently covered in MOD standards.

Organization	Yes or No	Question 6 Comment
NERC staff	No	NERC staff understands why the SDT has inserted the word “expected” before “dynamic behavior of Loads,” but we have concerns with this addition. We understand that a PC or TP that models the best current industry understanding of load behavior should not need to worry about compliance if that model does not match actual load response for all possible system conditions. However, we are concerned that this change to part 2.4.1 of Requirement R2 may be too accommodating. If a PC or TP has unrealistic expectations about load behavior, would this permit the use of unrealistic models? While we have struggled to develop an alternative proposal, we hope that the SDT will identify a way to address this concern.
Northeast Power Coordinating Council	No	There is insufficient information and experience regarding dynamic load modeling. It may also be included as a “sensitivity” analysis in 3.2, rather than requiring and expecting accurate representation of a dynamic load model. If this requirement is kept, a modeling standard must be written that is specific to dynamic loads. Change belongs in a modeling standard, not in TPL-001.
Hydro One Networks Inc.	No	There is insufficient information and experience regarding dynamic load modeling. Hence, this should not be a requirement but a guide or an item to be considered to the extent possible. It may also be included as a “sensitivity” analysis in 3.2, rather than requiring and expecting accurate representation of dynamic load model.
Transmission Issues Subcommittee	No	TIS believes that the term “expected” leaves the question as to “whose expectation.” It should be stated as to “expected...by the Transmission Planner.”

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 6 Comment
Exelon Transmission Planning	No	There is not an industry consensus around best practices for modeling the dynamic behavior or characteristics of load. It is premature to make this a requirement in an enforceable standard which would be held to this degree of subjective auditing.
Manitoba Hydro	No	The last two sentences “System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.” belong in the MOD standards. They are not required in TPL-001-2.
US Bureau of Reclamation	No	Not included in R2. See response to Question 3.2
CenterPoint Energy	No	The SDT did not incorporate CenterPoint Energy's previous comments regarding R2; therefore, CenterPoint Energy's concerns remain.
Ameren	No	Industry needs guidance regarding how to provide reasonable induction motor representation as opposed to generic models.
Hydro-Quebec TransEnergie	No	There is insufficient data available to accurately model system wide motor loads.
LCRA TSC	No	The first bullet item in Section 3.3.1 should be the same as the second bullet in Section 4.3.1. The wording is somewhat confusing in both. Also, the wording as proposed does not recognize that a high voltage limit could also be violated. Edits to the item as shown below are suggested. Tripping of generators where simulations show generation bus voltages or high side generation step up (GSU) voltages are outside known limits, or assumed to be outside generator steady state limits, or have reached the generator ride through voltage limit. Include in the assessment any assumptions made.
Tri-State Generation & Transmission	No	Rather than specifically call out induction motor loads, we recommend changing the second sentence to “Stability analysis shall include models that represent the expected dynamic behavior of system elements that could impact the study area.”
GTC	No	We have concerns for including induction motor representations in the load models without any study or bench-marking activities to meet the requirements of R2.4.1. This information should be supplied by the LSE as part of the MOD standard. We understand that the proposed standard will accept an aggregate system load model which represents the overall dynamic behavior of the load to relieve the burden of trying to develop specific induction motor load representation at each load bus. However this modeled system response will be considerably different compared to the actual system response which will open up the

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 6 Comment
		industry to unwarranted scrutiny and possible compliance violation investigations.
Consolidated Edison Co. of New York, Inc.	No	There is insufficient information and experience regarding dynamic load modeling. It may also be included as a “sensitivity” analysis in 3.2, rather than requiring and expecting accurate representation of a dynamic load model. If this requirement is kept, a modeling standard should be written that is specific to dynamic loads. This change belongs in a modeling standard, not in TPL-001.
NBSO	No	By implication, the response of induction motor load would need to be considered when modeling the expected dynamic behaviour of loads that could impact the study area. NBSO suggests re-wording parts of R2.4.1 as follows: System peak load levels shall include a model which represents the expected dynamic behaviour of loads that could impact the study area. An aggregate system load model which represents the overall expected dynamic behaviour of load is acceptable.
Central Maine Power Company New York State Electric & Gas New York Independent System Operator	No	We have not determined a need to model dynamic loads, and therefore have not benchmarked any such models. We recommend that prior to this requirement being in place, a modeling standard should exist that is specific to dynamic loads.
ERCOT ISO	No	ERCOT ISO suggests adding “best available” as a descriptor to load models. Distribution Providers (DPs)/Load Serving Entities (LSEs) are the appropriate NERC functional entities to provide dynamic load data. Accordingly, Planning Coordinators (PCs) and Transmission Planners (TPs) must rely on those entities for that data. Despite reliance on DPs/LSEs for this data, the Standard proposes to impose an obligation on PCs and TPs to include a load model representative of “expected” dynamic behavior. Simply put, PCs and TPs do not have this information and should not be subject to compliance liability risk for an issue that is beyond their control. This change will still accomplish the goal of reflecting dynamic data in the relevant models, while mitigating PC/TP compliance risk by basing their compliance on information that is within their control - i.e. the “best available” information. Based on this change, the language should read - “System peak Load levels shall include best available Load models which represent the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads”. This language is also a more accurate reflection of the Consideration of Comments by the Standard Drafting Team after the March 2010 comment period. To address this issue in the most appropriate manner, the Standard should be revised to establish an appropriate process for collection, reporting and use of dynamic data based on assigning obligations to the appropriate functional entities. In essence, DPs/LSEs should be required to collect the data and report it to TPs. Because TP models are the basis for PC models, the dynamic data will be included in PC models as part of the process. However, DPs and TPs should still only be required to use the “best available” data. Continued use of this language will mitigate the liability risk associated with a

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 6 Comment
		requirement related to data that is within the control of a third party. Even under a construct where DPs/LSEs are required to collect and report dynamic data, there is no guarantee they will do so and PCs/TPs should not be held accountable in those circumstances. Accordingly, PC/TP compliance risk will be mitigated by use of a “best available” standard.
GDS Associates, Inc.	No	We disagree with the content of this requirement based on several facts:- We believe that the dynamic behavior of the load cannot be accurately estimated beyond current time. We are concern about the effort required to ascertain the dynamic response of the load- The requirement references “Loads that could impact the study area” without specifying how an entity will identify these loads. Perhaps the standard should provide guidelines to determine which loads would impact the study area.
MidAmerican Energy	No	MidAmerican questions if the widespread use of composite load models really provides significant benefits to additional dynamic analyses over generic load conversion assumptions which have been historically used. The use of composite load models may result in more precise individual load models, but no more accurate dynamic simulations. This poorly worded requirement should be deleted in its entirety as providing additional burden without any additional reliability benefits. If the composite load model requirement must be kept, it should be modified to include the following bolded text:”...System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads, but without requiring a detailed load survey be conducted...”
Platte River Power Authority	Yes	For consistency, use the qualifier “expected” in the second sentence of Part 2.4.1 also, such that it reads “...represents the overall expected dynamic behavior...”
Xcel Energy	Yes	For consistency, use the qualifier “expected” in the second sentence of Part 2.4.1 also, such that it reads “...represents the overall *expected* dynamic behavior...”

3.4 Requirement R2, Part 2.5 – material clarification:

Summary Consideration:

The majority of respondents agree with the changes to these requirements and no changes to these requirements have been made based on stakeholder comments.

The SDT discussed defining ‘material change’ but did not believe that such a definition was appropriate in a continent-wide standard. With the wide variety in sizes and types of systems, the number of parameters that need to be considered, etc., there are too many variables involved. With the inclusion of Requirement R8 and the sharing of information, there is an opportunity for open discussion on such matters.

The SDT notes that Part 2.6.2 allows an entity to rely on a past study with a material change if “a technical rationale can be provided to demonstrate that System changes do not impact the performance results in the study area”. Therefore, it is up to the entities performing the study to provide the rationale based on changes, such as Load growth.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 7 Comment
Exelon Transmission Planning	No	The term ‘material changes’ is subjective. It is very difficult to determine a base case to study combinations of generator additions on a changing transmission network in the 6 to 10 year time period to be used for dynamic simulations. Dynamic studies should be performed whenever new generator interconnections are proposed and it is at that time where meaningful calculations can be performed. The long term six to ten year out dynamic studies for groupings of potential units should be done at a high level, if at all.
Florida Reliability Coordinating Council, Inc - Transmission Working Group	No	This change does not clarify material. Material should be quantified somehow. We recommend changing the phrase “material generation additions or changes” to “generation in the vicinity with additions of changes larger than 200 MW”.
Lakeland Electric	No	Please consider removing R2.6.2. The “any material change” language can cause utilities perform studies due to material changes outside of and remote to its system.

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 7 Comment
Orlando Utilities Commission	No	I agree with what I think is the intent. The word "Material" is meant to allow for changes in model to occur that are "small" relative to the TP/PC. For example the 400 MW generator that might be built in 10 years by another utility over a hundred miles, several dozen buses and generators away to not force new study work. However as written in 2.5 it requires you to define what a material change is, and could be applied to mean every change must be identified and explained rather than an overarching rationale that would only have you looking for changes that meet the material criteria. But then in 2.6.2 the word material is used with no obligation to explain what material is, only to explain if a material change would not impact the results in a study area. I recommend leaving the term material, but setting a requirement, measure, or definition that requires the TP/PC to define what they consider material specific to their system and circumstance. Since this will by the hetroogenous nature of the grid be different for each it may not be reasonable to pre-define what is reliable. Just as was done with many items in the ATC (MOD) standards, require that it be documented and questions on that rationale be answered. If a specific level of technical oversight is desired, consider requiring that description to be on file with the regional entity and approved by their planning committee. I think the team is heading in a good direction, it's just how the words will be applied that concern me. This may be a case where an Example or two would go a long way towards providing guidance to entities and auditors.
Manitoba Hydro	No	Adding the word “material” does not clarify Part 2.5. The word “material” can be interpreted in many ways and is subjective. In order to have a consistent approach by all TPs, the drafting team should add a definition of the term “material”. One TP may consider a new 200 MW unit as not being material because there are several larger units in the TPs system.
US Bureau of Reclamation	No	The term "material" is arbitrary. It is suggested that a specific value be used to trigger the assessment.
CenterPoint Energy	No	The SDT did not incorporate CenterPoint Energy's previous comments regarding R2; therefore, CenterPoint Energy's concerns remain.
Progress Energy	No	PE agrees in general with the changes made to R2.5. PE disagrees, however, with the language stipulating that current and past studies be qualified by the language in R2.6 Part 2.6.2 (see notes for Question 3.1 regarding recommending changes with regard to R2.6.2).
Tucson Electric Power Company	No	If a material change (generator addition/retirement, new generator models based on unit testing, or transmission line or non-distribution transformer addition) is not planned for the longer-term planning horizon, do the longer-term stability studies need to be performed? TEP's agreement/disagreement with Part 2.4.1 is

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 7 Comment
		dependent on the response to this question. If the answer is the studies do not need to be performed, then TEP supports these changes.
GDS Associates, Inc.	No	We are not sure what will be included in these “material generation additions or changes”. Perhaps the standard should provide guidelines to determine what are these material changes or additions?
Xcel Energy	No	It appears that the requirement appended at the end of Part 2.5 “...and shall include documentation to support the technical rationale for determining material changes.” is duplicative of Part 2.6.2. Please address this apparent redundancy.
NERC staff	Yes	NERC staff supports inserting the word “material” in the reference to assessing the impact of proposed generation. We have some concern that this change leaves this part of the requirement open to interpretation, but we also understand the need to permit some degree of engineering judgment to be applied. It would not be appropriate to require that every potential generation addition be included in the assessment where some proposed additions may by inspection be deemed to be immaterial due to size and/or interconnection location.
IRC Standards Review Committee	Yes	However, the requirement infers that a subjective judgment from a compliance auditor will be required.
Bonneville Power Administration	Yes	It should be noted that if there is more generation proposed in an area than there load and export capability, all proposed material generation additions would not be represented. Determining what future generation additions to include in the Long-Term Transmission Planning Horizon may be based on a non-technical rationale rather than a technical rationale.
Western Area Power Administration	Yes	The drafting team could provide guidance on what is "material". In Part 2.5, should “annually” be inserted after “shall be assessed” to make it consistent with Parts 2.1, 2.2, 2.3 and 2.4? If the omission is intentional in 2.5, please explain why.
Platte River Power Authority	Yes	I like the flexibility you give the PC and TP to define what ‘material’ means in their ‘documentation to support the technical rationale for determining material changes.’ In Part 2.5 this rationale will decide whether or not any Long-Term Stability studies are required for the Planning Assessment. And in Part 2.6.2 this rationale will be a factor in qualifying a past study.
Independent Electricity System	Yes	We do not have a concern with this change but we don’t think it is necessary. It is not a requirement, and

4. The SDT has revised the header notes based on industry comments to the initial ballot. If you do not support these changes, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

The SDT clarified the language of header note ‘i’ as a result of comments received as follows:

- i. The response of voltage sensitive Load ~~including Load~~ that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements.

The majority of respondents agree with the changes to the header notes and no other changes to the header notes have been made based on stakeholder comments.

Requirements cannot be ‘hidden’ in the Table because the Table is specifically cited in the requirements text and is thus part of the requirements.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 8 Comment
Northeast Power Coordinating Council	No	Header note (i) in the first Table 1 (p. 10) could imply that voltage-varying load shall not be used to meet steady state performance requirements. Steady state load models in use include voltage-varying loads. The explicit representation of (voltage-dependent) load models is perfectly consistent with the requirements defined in R1 (which calls for a comprehensive representation of system components and their expected operating status in the planning assessment period) and the impetus to the creation of more specific load models in dynamic assessments found Requirement 2.4 of this draft of TPL-001-2. It is a known that depressed voltage conditions cause certain system elements to perform below their rated capacity. For example, capacitors provide less voltage support and voltage controlling transformers are impeded by their finite tap range to direct VAR flow into areas affected by low voltage conditions. Certain load types, on the other hand, provide a self-compensating relief to depressed voltage by naturally decreasing demand in a manner proportional to their characteristics, without operator intervention. Choosing to negate the voltage-dependence of one of these system elements (load, in our case) results in an inaccurate system representation that, in turn, may lead to erroneous assessments of the reliability state of the interconnected system and, potentially, to the implementation of unwarranted system upgrades. This note should be revised

Organization	Yes or No	Question 8 Comment
		to only reference loads which are disconnected due to voltage.
Transmission Issues Subcommittee	No	Delete the word “voltage” from the last header note J concerning Stability Only. All types of transient stability must be observed.
LCRA TSC	No	<p>The third bullet of 4.3.1 requires the addition of relay models for stability studies. This type of analysis is performed today by scripting the tripping of multiple lines due to breaker failure events. The inclusion of relay models into the stability study will result in added complexity and an over reliance on relay models for system stability assessment. The stability assessment should assess stability resulting from the operation of relays as opposed to reliance on a relay model for proper system representations. Assurance of the proper operation of relays results from the analysis performed to set relays not from stability studies. From Section 4.3.1: “Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.”</p> <p>Section 4.5 requires that “The rationale for those Contingencies selected for evaluation shall be available as supporting information.” This will have to be developed.</p> <p>Requirement R5 requires the establishment of criteria for transient voltage response of the system. This seems unnecessary given the proposed changes to Table 1. The proposed changes to table 1 seem to make clear the type of system response that is allowable through its specification of what is allowable in terms of interruptions to Firm Transmission and Non-Consequential loads. R5 states: “Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level.”</p>
Consolidated Edison Co. of New York, Inc.	No	<p>o Header note (i) in the first Table 1 (p. 10) The explicit representation of (voltage-dependent) load models is perfectly consistent with the requirements defined in R1 (which calls for a comprehensive representation of system components and their expected operating status in the planning assessment period) and the impetus to the creation of more specific load models in dynamic assessments found Requirement 2.4 of this draft of TPL-001-2. It is a known that depressed voltage conditions cause certain system elements to perform below their rated capacity. 		system and, potentially, to the implementation of unwarranted system upgrades.
Central Maine Power Company New York State Electric & Gas Corp New York Independent System Operator	No	Header note (i) in the first Table 1 could imply that voltage-varying load shall not be used to meet steady state performance requirements. NYISO steady state load models include voltage-varying loads. This note should be revised to only reference loads which are disconnected due to voltage.
MidAmerican Energy	No	The reference to BES should be placed back into Note a in the header above table 1.
Xcel Energy	No	<p>Although we support the revised header notes, we believe that the following additional changes are needed to enhance clarity and improve consistency:</p> <p>We are unable to see the compelling need and/or the value of separating the header notes in three categories. Since the applicability of each header to either one or both steady-state and stability performance is obvious from its respective verbiage, we suggest eliminating the categorization. This will also allow the header notes to be reordered/regrouped as per related functionality, thus improving the Table 1 readability.</p> <p>Following is a suggested re-ordering of header notes:</p> <ul style="list-style-type: none"> a. Applicable Facility Ratings shall not be exceeded. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Planning event P0 is applicable to steady state only. c. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event except P0. d. The response of voltage sensitive Load including Load that is disconnected from the System by end-user equipment as a consequence of any event shall not be used to meet steady state performance requirements. e. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits established by the Planning Coordinator and Transmission Planner. f. Transient voltage response shall be within acceptable limits as established by the Planning Coordinator and Transmission Planner. g. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. h. Simulate the removal of all elements that Protection Systems and other controls are expected

Organization	Yes or No	Question 8 Comment
<p>MRO's NERC Standards Review Subcommittee</p> <p>American Transmission Company</p>	<p>Yes</p>	<p>to automatically disconnect for each event. Simulate Normal Clearing unless otherwise specified.</p> <p>We offer the major suggestion that Requirements not be created in the Performance Table and be absent from the Requirement section. Requirements should only be referred to in the Performance Table after they already exist in the Requirement section.</p> <p>a. Notes “f” and “g” under “Steady State Only” section in the Table 1 header create requirements (e.g. use the verb, “shall”) that do not appear in the Requirements section. We suggest adding R3.3.5, which could read, “Applicable System Operating Limits for the planning horizon shall not be exceeded.” [After R3.3.5 is added, Notes “f” and “g” should be revised and refer to R3.3.5.]</p> <p>b. Note “i” under “Steady State Only” section in the Table 1 header creates a requirement (e.g. use the verb, “shall”) that does not appear in the Requirements section. We suggest adding R3.3.6, which could read, “The response of voltage sensitive Load including Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state voltage requirements.” [After R3.3.6 is added, Note “d” should be revised to refer to R3.3.6.</p> <p>c. Note “j” under the “Stability Only” section in the Table 1 header creates a requirement (e.g. use the verb, “shall”) that does not appear in the Requirements section. We suggest adding R4.1.4, which could read, “Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner”. [After R4.1.4 is added, Note “j” should be revised to refer to R4.1.4.]</p>
<p>Western Area Power Administration</p>	<p>Yes</p>	<p>Following is a suggested re-ordering of header notes to replace of the three categories concept - same information: a. Applicable Facility Ratings shall not be exceeded. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Planning event P0 is applicable to steady state only. c. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event except P0. d. The response of voltage sensitive Load including Load that is disconnected from the System by end-user equipment as a consequence of any event shall not be used to meet steady state performance requirements. e. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits established by the Planning Coordinator and Transmission Planner. f. Transient voltage response shall be within acceptable limits as established by the Planning Coordinator and Transmission Planner. g. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. h. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. Simulate Normal Clearing unless otherwise specified.</p>
<p>NERC staff</p>	<p>Yes</p>	<p>NERC staff supports the changes to the header notes in Table 1.</p>

5.

The SDT has revised the performance table (including the list of extreme events and footnotes) based on industry comments to the initial ballot. If you do not support these changes, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

The SDT has made the following clarifying changes to address concerns raised in the comments:

- P0 – delete superscript 9 in column 6: No⁹
- P5 event description: Delayed Fault -Clearing –due to the failure of a non-redundant relay¹³ protecting the Faulted element to operate as designed, for one of the following:
- Extreme events language for Stability events has been made consistent with P5.
- Added ‘Breaker’ to the Bus-tie and non-Bus-tie phrases in P2 and P4

No other changes were made to the Performance Table based on stakeholder comments.

The SDT fully realizes that Project 2010-11 must reach resolution prior to finalizing TPL-001-2 and stated same in the information attached with the fifth posting of Project 2006-02.

The SDT has made the language in Requirement R2, part 2.8.2 consistent with that in Requirement R2, part 2.7.4:

2.8.2 Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 9 Comment
NERC staff		NERC staff is concerned with P5 and footnote 9 and thus cannot support these changes in their entirety. First, a revision to the Draft 4 definition of P5 should be used in lieu of the current Draft 5 version: “Loss of multiple elements caused by the Fault clearing consistent with failure of a single Protection System while clearing a fault on one of the following: . . .”After reviewing the P5 contingency throughout various drafts of this standard, along with existing Table 1 for TPL-001 through TPL-004, NERC staff’s primary concern is that this most recent version is going in the wrong direction by becoming too limiting regarding which Protection System component failures are covered. Draft 5 is an improvement because it removes the reference to loss of

Organization	Yes or No	Question 9 Comment
		<p>multiple elements in Draft 4 (which defined P5 as “Loss of multiple elements caused by the failure of a single Protection System while clearing a fault on one of the following: . . .”). Draft 5 takes a step backward, however, by referring to Delayed Fault Clearing. The advantage of not referring to Delayed Fault Clearing is that for cases where redundant protection systems are provided, the fault clearing may not be delayed even when a single Protection System failure occurs. Ideally, NERC staff believes that P5 should refer to “failure of any component of a Protection System,” but NERC staff recognizes that we cannot get there until the term Protection System is redefined and Project 2009-07-Reliability of Protection Systems is underway. Until that change is possible, NERC staff encourages the SDT to use the revised version of P5 proposed above.</p> <p>A second concern is with footnote 9, which is used numerous times in Table 1. System adjustments may be used in two different settings: the first is to address the aftermath of a particular Contingency; the second is to prepare for the next Contingency. Staff suggests that the current footnote 9 have this language added: “Post-Contingency Ccurtailment of Firm Transmission Service to address the simulated contingency, when coupled with” Footnote 9 is used in the column labeled “Interruption of Firm Transmission Service Allowed” whenever a “No” is provided. The footnote 9 in this column has to do with System adjustments that address the aftermath of the Contingency that is being simulated. Therefore, no footnote 9 appears appropriate for category P0 (No Contingency). The reference in footnote 9 to no load loss and staying within applicable Facility rating, including those on a neighboring system, is sufficient for addressing the aftermath of the Contingency being simulated.</p> <p>To address next Contingency, an additional footnote is needed in the “Initial System Condition” column for category P3 and category P6. The following is suggested: “System adjustments to prepare for the next Contingency must be completed within 30 minutes.” Footnote 9 is used in the column labeled “Initial System Condition” for category P3 and category P6, and these two categories define the loss of an Element “followed by System adjustments” and then followed by the loss of a second Element. It is unclear whether the intent in footnote 9 in these two cases is meant to address the same issue referenced above (i.e. the aftermath of the Contingency being simulated) or whether it is intended to address the next Contingency. Thus, both situations need to be addressed using the suggestions indicated above.</p>
<p>Northeast Power Coordinating Council Consolidated Edison Co. of New York, Inc.</p>		<p>To support the change to P5, other items need to also be modified. In Table 1 - Steady State & Stability Performance Extreme Events (p. 12), in the Stability Section, the language should be made similar to wording in P5. Protection System should be removed and replaced with the words “relay failure”. This change should be made for 2a through 2d:2. Local or wide area events affecting the Transmission System such as: a. 3\bar{A} fault on generator with stuck breaker¹⁰ or a relay failure resulting in Delayed Fault Clearing. b. 3\bar{A} fault on Transmission circuit with stuck breaker¹⁰ or a relay failure resulting in Delayed Fault Clearing. c. 3\bar{A} fault on transformer with stuck breaker¹⁰ or a relay failure resulting in Delayed Fault Clearing. d. 3\bar{A} fault on bus section with stuck breaker¹⁰ or a relay failure resulting in Delayed Fault Clearing.</p>

Organization	Yes or No	Question 9 Comment
		<p>Note 11 (p. 14) needs clarification as shown: Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for a total of 1 mile or less.</p> <p>There are two tables labeled “Table 1”. Suggest that the extreme events table be renamed “Table 2”.</p>
MRO's NERC Standards Review Subcommittee		<p>We offer the major suggestion that the P3 Category performance criteria be modified to apply only to the loss of two generators. The SDT properly recognizes that generator outages are significantly more probable than line or transformer outages and should be “higher” in the category list. However given the clearly higher probability of generator outages, the probability of the loss of two generators is clearly higher than the loss of a generator and line or the loss of a generator and transformer. Therefore, if the loss of two generators is in the P3 category, then the loss of a generator and line or transformer should be clearly “lower” in the category list. We suggest the listing of: the loss of a generator and some other element (e.g. transmission circuit, transformer, shunt device, and single pole of DC line) be moved to a lower event category, such as the P6 Category by adding “1. Generator” to the listing in the Initial System Condition (Loss of . . .) column.</p> <p>Item 2.a in the Extreme Events, Steady State section - Clarify the meaning of the loss of multiple circuits in Item 2.a by using wording similar to P7. We suggest this text: “a. Loss of three or more circuits that share a common structure.”</p> <p>Footnote 6 - Further clarify the applicable shunt devices in Footnote 6 with this suggested text: “6. Requirements which are applicable to shunt devices, also apply to FACTS devices that are connected to ground, but not instrument voltage transformers or surge arresters.”</p>
Bonneville Power Administration		<p>Table 1, P5 currently requires the study of “[d]elayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed”. As written, this requirement does not recognize the use of redundant relays for primary protection. In some cases side by side relays are used to provide primary fault tripping if one relay fails to operate. Per the requirement as stated, the redundant relay would provide no value in meeting this requirement. Please revise to acknowledge backup relays: “Single failure of a protection relay¹³ protecting the Faulted element to operate as designed, resulting in backup relay actions or Delayed Fault Clearing, for one of the following”.</p> <p>In Table 1, P2 and P3, the last column “Non-Consequential Load Loss Allowed” where the requirement “No¹²” appears, and in footnote 12, the standard as proposed does not allow for any Non-Consequential Load Loss. When the Non-Consequential Load Loss (footnote b) issue is clarified in Project 2010-11 this requirement may be changed. Therefore the proposed footnote 12 should include a provision to default to the existing footnote “b” in TPL-002-0 until Project 2010-11 is decided. Please revise footnote 12 to read, “Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here. In the interim, planned or controlled interruption of electric supply to radial</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 9 Comment
		customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.”
Exelon Transmission Planning		<p>Comments: The term ‘HV’ in the performance table should be defined as ‘Bulk Electric System elements up to 300 kV, not simply all elements ‘below 300 kV’.</p> <p>Footnote 12 should be clarified to specifically state the requirements before voting takes place. The performance criteria should be based on the voltage level of the element experiencing stress due to the contingency, not based on the voltage level of the outaged element. It does not seem to make sense that the loss of a 500 kV bus would not allow for any non-consequential load shedding unless the bus contained a 500 to 230 kV transformer, in which case additional load shedding would be allowed. If outages on a 230 kV system, such as bus fault with stuck breaker, were to cause overloads on a 500 kV network it is acceptable to shed load, but if the outages were on the 500 kV system originally it would not be acceptable to shed additional load. It seems as if it should be the severity of the situation and the elements involved that would dictate allowable remedial actions and not the initial cause of the disturbance. If, for example, there was a 500 kV contingency outage that caused problems on the 230 kV system there would be a problem that may require load shedding on the 230 kV system. If there were a 230 kV contingency or series of contingencies that caused overloads on the 500 kV system, it would be more difficult to find enough lower voltage load to shed to bring the 500 kV system back to applicable ratings or conditions. The inability to shed non-consequential load could theoretically be resolved by hanging a small EHV / HV transformer on a particular bus, or by tapping a EHV line with an auto transformer.</p>
Southern Company		NO. We wish to make a comment on the stability extreme event table: Changes were made in planning event P5 to narrow the focus to specific relay failures. The same changes are needed for stability extreme event 2a, 2b, 2c, and 2d.
Western Electricity Coordinating Council Arizona Public Service Company PNM SRP California Energy Commission Los Angeles Department of		<p>Table 1, P5 currently requires the study of “[d]elayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed”. As written, this requirement does not recognize the use of redundant relays for primary protection. In some cases side by side relays are used to provide primary fault tripping if one relay fails to operate. Per the requirement as stated, the redundant relay would provide no value in meeting this requirement. Please revise to acknowledge backup relays: “Single failure of a protection relay¹³ protecting the Faulted element to operate as designed, resulting in backup relay actions or Delayed Fault Clearing, for one of the following”.</p> <p>In Table 1, P2 and P3, the last column “Non-Consequential Load Loss Allowed” where the requirement “No¹²” appears, and in footnote 12, the standard as proposed does not allow for any Non-Consequential</p>

Water and Power Pacific Gas and Electric Company Modesto Irrigation District Puget Sound Energy Sacramento Municipal Utility District		Load Loss. When the Non-Consequential Load Loss (footnote b) issue is clarified in Project 2010-11 this requirement may be changed. Therefore, if this proposed Standard is enforced before Project 2010-11 is completed, entities will be required to meet this No Non-Consequential Load Loss requirement without the exception allowed in the existing TPL-002-0, footnote “b”. This will require immediate redesigns to meet this particular requirement. The unintended consequence could be that operators of local systems that are currently networked may opt to begin operation as radial systems, and future designs for local systems may be radial, at any voltage level. We suggest that the proposed footnote 12 include a provision to default to the existing footnote “b” in TPL-002-0 until Project 2010-11 is decided. Please revise footnote 12 to read, “Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here. In the interim, planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.” Timing of this project and project 2010-11 is critical. It would be very difficult to vote to approve the proposed TPL-001-2 prior to knowing the outcome of Project 2010-11 (footnote b issue).
E.ON U.S.		E.ON U.S. believes that Table 1 should be formatted to avoid having the tables split by page breakers. In addition, tables spanning across multiple pages should have headers at the top of each page.
Florida Reliability Coordinating Council, Inc - Transmission Working Group		Footnote 12 performance requirements of Table 1 should allow the loss of non-consequential load for all contingency categories except for P0. The disallowance of load loss does not provide any real benefit to the reliability of the BES and is an unnecessary overreach into local quality of service issues that are best addressed by State, Provincial or Municipal authorities. There may be circumstances such as high local transmission costs or local opposition to transmission construction where prohibition of non-consequential load loss represents a poor cost/benefit or quality of life tradeoff. Having a provision at the regional level that a PA or TP can have a certain amount of non-consequential load loss designed or planned in to its system that would be reasonable if it is acceptable to the RE and does not have an adverse impact on the remaining BES. In lieu of such a RE provision, providing a quantitative cap in non-consequential load loss such as 100 MW may be rationale compromise in the goal of limiting load loss for the more probable outage events. Our preference would be to retain the capability of limited non-consequential load loss. Footnote 9 should also be under consideration as part of Project 2010-11 and should be noted as such for clarification.
Western Area Power Administration		In footnotes 9 and 12, two critical issues are being addressed in large part via these "clarifying" footnotes. These are curtailment of "Firm Transmission Service" (which seems primarily to be a contract/scheduling issue) and the loss of "Non-Consequential Load." Perhaps these issues should receive more attention in the

Timing of this project and project 2010-11 is critical. It would be very difficult to vote to approve the proposed TPL-001-2 prior to knowing the outcome of Project 2010-11 (footnote b issue).</p> <p>In Table 1 - Planning Events - Suggest changing the description for Events P2-3, P2-4, P4 and P4-6 to use the term 'Bus-tie Breaker' or 'non-Bus-tie Breaker' as applicable.</p> <p>In Table 1 - Extreme Events - Stability - Items 2a-2d, do you mean 'Protection System failure' here, or do you want to change to 'relay failure' to be consistent with changes in P5?</p>
Orlando Utilities Commission		<p>I generally agree with the direction the team has gone.</p> <p>Footnote 9 should also be highlighted as being part of the project 2010-11 discussion just as footnote 12 is.</p>
Manitoba Hydro		<p>In point g, violations are noted in terms of post-Contingency voltage deviations rather than post-Contingency voltage limits. This may lead to confusion, as some utilities evaluate performance based on a post-Contingency voltage deviation criterion while other utilities evaluate performance based on post-Contingency voltage limits. This same comment applies to Requirement R5.Suggested rewording for point g: System steady state voltages and post-Contingency voltages or voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. Suggested rewording for the first sentence in Requirement R5: Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltages or voltage deviations, and the transient voltage response for its System.</p> <p>Note 12 states that an outstanding issue related to non-consequential load loss is being discussed. This will create a lot of uncertainty. Manitoba Hydro could not support this standard unless the resolution of Note B is known.</p>
CenterPoint Energy		<p>CenterPoint Energy appreciates the effort put forth by the SDT in revising the performance table. The current draft of P5 is preferable to previous versions.</p>
TVA Transmission Planning & Compliance		<p>TVA is concerned about footnote 12 (known as footnote b in existing TPL standards). TVA believes that utilities should be given some freedom in dropping local load in response to N-1 events as long as overall</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 9 Comment
		<p>BES reliability is not impacted. Otherwise significant capital improvements will be required that will have no overall reliability gain for the Bulk Electric System.</p> <p>TVA does agree with the revisions made specifically to the P5 event.</p> <p>TVA wishes to make a comment on the stability extreme event table: Changes were made in planning event P5 to narrow the focus to specific relay failures. The same changes are needed for stability extreme event 2a, 2b, 2c, and 2d.</p>
SMUD		<p>For the Western Interconnection, the performance level for a Bus-tie breaker fault under TPL-001-2, Table 1, Item P2-4, Notes (a) and (f), requires no thermal overloads and no cascading. While, FAC-010-2.1, R1.2, R2.5-R2.6, as modified by E1.1, E1.1.7, E1.3, and E1.3.1 requires a different performance level of no cascading. Please explain why this regional variance is not included under TPL-001-2, Item E.</p>
California ISO		<p>We support these changes, although we suggest that the proposed footnote 12 include an interim provision to default to the existing footnote “b” in TPL-002-0 until Project 2010-11 is decided. Please revise footnote 12 to read, “Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here. In the interim, planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.”</p>
Seattle City Light		<p>Table 1, P5 does not recognize the existence of redundant (or backup) relays. These are an integral part of the protection system design and should be considered in analysis of SLG faults. The TPL standard should encourage redundant, fail-safe systems, not ignore them.</p> <p>In Table 1, P2 and P3, we have a concern about not allowing non-consequential load loss. Project 2010-11 is deciding on this issue, but is not completed (see footnote 12). Should the standard become effective before this project is completed, no non-consequential load loss would be allowed, requiring many transmission additions and reconfigurations. Please change the "NO" in the last column to "YES" until the completion of Project 2010-11.</p>
ISO New England Inc.		<p>We are supportive of the change to P5. However, in making this modification, other items need to also be changed. In Table 1 - Stability, the language should be made similar to wording in P5. Protection System should be removed and replaced with the words “relay failure”. This change should be made for 2a through 2d:2. Local or wide area events affecting the Transmission System such as: a. 3Å~ fault on generator with stuck breaker10 or a relay failure resulting in Delayed Fault Clearing. b. 3Å~ fault on Transmission circuit with</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 9 Comment
		<p>stuck breaker10 or a relay failure resulting in Delayed Fault Clearing. c. 3Å~ fault on transformer with stuck breaker10 or a relay failure resulting in Delayed Fault Clearing. d. 3Å~ fault on bus section with stuck breaker10 or a relay failure resulting in Delayed Fault Clearing.</p> <p>We also believe that Note 11 needs clarifying wording as shown below:"Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for a total of 1 mile or less"</p>
<p>United Illuminating National Grid Central Maine Power Company New York State Electric & Gas Corp</p>		<p>In Table 1 - Stability, Make language similar to wording in P5. "Protection System" should be removed and replaced with the words "relay failure". This would avoid future interpretation issues about the intent of this requirement (as we understand it) to exclude more severe though less likely failures such as battery systems. This change should be made for 2a through 2d on page 12).In Note 11 (page 14) ADD the wording shown in "quotes" below: Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for "a total of" 1 mile or less.</p>
<p>Hydro-Quebec TransEnergie</p>		<p>In table 1 on page 12 (Stability section), Relay failure should replace Protection System</p>
<p>LCRA TSC</p>		<p>An important footnote to Table 1 is omitted from this proposed revision. This omission prevents adequate evaluation of the footnote. Footnote 12 in Table 1 is no longer applied to P2.1, P2.2, P2.3, P4, and P5. The footnote states: "Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here." The footnote should be removed from the proposed revision until Project 2010-11 is concluded.</p>
<p>American Transmission Company</p>		<p>We offer the major suggestion that the P3 Category performance criteria be modified to apply only to the loss of two generators. The SDT properly recognizes that generator outages are significantly more probable than line or transformer outages and should be "higher" in the category list. However given the clearly higher probability of generator outages, the probability of the loss of two generators is clearly higher than the loss of a generator and line or the loss of a generator and transformer. Therefore, if the loss of two generators is in the P3 category, then the loss of a generator and line or transformer should be clearly "lower" in the category list. We suggest the listing of: the loss of a generator and some other element (e.g. transmission circuit, transformer, shunt device, and single pole of DC line) be moved to a lower event category, such as the P6 Category by adding "1. Generator" to the listing in the Initial System Condition (Loss of . . .) column.</p> <p>We offer the minor suggestion that Item 2.a in the Extreme Events, Steady State section - Clarify the meaning of the loss of multiple circuits in Item 2.a by using wording similar to P7. We suggest this text: "a. Loss of three or more circuits that share a common structure."</p>

Organization	Yes or No	Question 9 Comment
		<p>We offer the minor suggestion that Footnote 6 - Further clarify the applicable shunt devices in Footnote 6 with this suggested text: “6. Requirements which are applicable to shunt devices, also apply to FACTS devices that are connected to ground, but not instrument voltage transformers or surge arresters.”</p> <p>ATC has significant concerns with Q3.2 (R2.1.4 & R2.4.3), Q4 (Table requirements) and Q5 (P3 scope), as noted above.</p> <p>In addition, ATC offers the following suggestions to promote proper Reliability Standard quality and content.</p> <p>(1.) Revise the Planning Assessment definition to more explicitly apply to the BES and the TPL-001 requirements. We suggest text of: “Planning Assessment: Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies in the BES from the steady state and stability performance requirements set forth in the TPL-001 standard.”</p> <p>2.) R2.1.5 - We propose replacing the term ‘major Transmission’ with “BES” because BES is a well defined term, while the term ‘major Transmission’ is not.</p> <p>(3.) Add R2.3.1 - We suggest the addition of a R2.3.1 requirement to emulate the distinction between the requirement to perform a short circuit assessment and conduct required studies or analysis to support the assessment (e.g. R2.1/R2.1.1 and R2.2/R2.2.1). We propose wording such as, “Perform an analysis for at least one year in the Near Term Transmission Planning Horizon.” This requirement would set an expectation that an analysis should be conducted to at least one or more years in the near-term planning horizon, rather than imply that an analysis of all five years in the near-term planning horizon must be conducted.</p> <p>4.) R2.7.4 - We suggest that the wording of R2.7.4 be the same as R.2.8.2. Otherwise, we propose that R2.7.4 and R2.8.2 be revised with wording like, “. . . implementation status of identified Corrective Action Plans for System Facilities and Operating Procedures.” to clarify that the identified system facilities and operating procedures refer only to those that were in the previous year’s Corrective Action Plans.</p> <p>(5.) R3.3.1 - The term of ‘controls’ is ambiguous and not defined, unlike the term, ‘Protection Systems’, which is defined. Therefore, we suggest that this item be defined or more clearly described to avoid the risk of different and possibly contradictory interpretations by TPs, PCs, and auditors.</p> <p>(6.) R3.3., bullet #1 - We suggest qualifying which generating units to consider and which voltage limits to simulate with revised wording like, “Trip generating units that are connected to the BES when actual or assumed minimum generator steady state or ride through voltage limits are known and simulations show voltages may fall below the voltage limit. If assumed voltage limits are used, then they should be included in the assessment”. The requirement should not apply to all relevant generating units until one of the MOD standards requires all Generator Owners to provide their minimum generating unit voltage limits to the TP and PC. If the wording of R3.3.1, bullet #1 must be different from its counterpart, R4.3.1, then please explain the reasons for any differences.</p>

Organization	Yes or No	Question 9 Comment
		<p>(7.) R3.4.1 - Compliance with the requirement “to coordinate” is problematic and non-measurable. We suggest replacing it with the requirement “to communicate”.</p> <p>8.) R3.5 - We interpret that R3.5 requires the TP and PC to conduct an evaluation of possible actions to reduce the likelihood or impact of extreme events, which produce the more severe impacts, if cascading outages may occur. Does the drafting team intend for the TP and PC to fulfill this requirement for at least one event in each of the five categories (i.e. 3 steady state and 2 stability) or in each of the 21 categories/sub-categories (i.e. 14 steady state and 7 stability). Also, if the resulting cascading outages do not result in any overloads, under-voltages, voltage collapse, or loss of generator synchronization, then should the evaluation of possible actions to reduce likelihood or impact be required?</p> <p>(9.) R4.1.1 - We suggest that there should be some qualification of which generating units are referred to in this requirement. We propose that the requirement say, “No generating unit connected to the BES shall pull out of synchronism.” For example, some utilities include smaller generation units that are connected at voltages below 100 kV and even down to distribution voltage in their base cases.</p> <p>(10.) R4.1.2 - We propose that the wording of this requirement be revised to reflect the same BES qualification of the generating unit that we noted in R4.1.1 above.</p> <p>(11.) R4.3.1 - This requirement refers to high speed reclosing and we presume that this is special high speed reclosing that is completed in several cycles, rather than the normal high speed reclosing that is completed in a number of seconds. We recommend that the term high speed reclosing be more clearly defined for this sub-requirement.</p> <p>(12.) R5 - We propose removing the criteria item, “post-Contingency voltage deviation”, because this criterion has not been developed and used widely enough in the industry to be introduced into the standards.</p> <p>(13.) R7 - Revise part of the requirement text to read, “. . . identify each entity’s individual and joint responsibilities . . .” to provide better clarity. Perhaps this requirement should be listed at the beginning of the Requirements section, instead being mentioned near the end of this section.</p> <p>(14.) Change the forward referencing to backward referencing. We agree with R2.6, R3.1, R3.5, R4.1, and 4.2. However, we suggest that the requirements be ordered so that all of the references refer back to earlier text, rather later text to be consistent with the rest of this standard and other referencing in this standard (e.g. R2.1.3, R2.1.4, R2.4.3, R3, R3.3, R3.5, R4, R4.3, R4.4, R4.5), as well as other standards.</p>
Tri-State Generation & Transmission		<p>Table 1, P5 does not seem to account for redundant relays in the Protection System to mitigate potential relay failure. We recommend changing the “Event” to “Delayed Fault Clearing due to the failure of a relay to operate as designed, if that is the only relay protecting the Faulted element, for one of the following:”</p> <p>In Table 1, P2 and P3, the last column “Non-Consequential Load Loss Allowed” where the requirement</p>

Organization	Yes or No	Question 9 Comment
		<p>"No12" appears, and in footnote 12, the standard as proposed does not allow for any Non-Consequential Load Loss. When the Non-Consequential Load Loss (footnote b) issue is clarified in Project 2010-11 this requirement may be changed. Therefore, if this proposed Standard is enforced before Project 2010-11 is completed, entities will be required to meet this No Non-Consequential Load Loss requirement without the exception allowed in the existing TPL-002-0, footnote "b". This will require immediate redesigns to meet this particular requirement. The unintended consequence could be that operators of local systems that are currently networked may opt to begin operation as radial systems, and future designs for local systems may be radial, at any voltage level. We suggest that the proposed footnote 12 include a provision to default to the existing footnote "b" in TPL-002-0 until Project 2010-11 is decided. Please revise footnote 12 to read, "Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here. In the interim, planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers." Timing of this project and project 2010-11 is critical. It would be very difficult to vote to approve the proposed TPL-001-2 prior to knowing the outcome of Project 2010-11 (footnote b issue).</p> <p>Second, we are unclear why voltage relays are included in footnote 13 and think they can be removed.</p> <p>Third, in the Extreme Events - Stability section of Table 1, items 2a-2d "Protection System failure" should be changed to "relay failure" to be consistent with Table 1, Category P5.</p>
Lakeland Electric		<p>The performance requirements of Table 1 do not allow the loss of non-consequential load for single and multiple contingency events. The disallowance of load loss does not provide any real benefit to the reliability of the BES and is an unnecessary overreach into local quality of service issues that are best addressed by State, Provincial or Municipal authorities. There may be circumstances such as high local transmission costs or local opposition to transmission construction where prohibition of non-consequential load loss represents a poor cost/benefit or quality of life tradeoff. Having a provision at the regional level that a PA or TP can have a certain amount of non-consequential load loss designed or planned in to its system that would be reasonable if it is acceptable to the RE and does not have an adverse impact on the remaining BES. In lieu of such a RE provision, providing a quantitative cap in non-consequential load loss such as 100 MW may be rationale compromise in the goal of limiting load loss for the more probable outage events. Our preference would be to retain the capability of limited non-consequential load loss. It is our understanding that footnote 9 is under consideration as part of Project 2010-11 and should be noted as such for clarification.</p>
NBSO		<p>For consistency, 'Protection System' should be replaced with 'relay' on Table 1 (p12) Stability Section, items</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 9 Comment
Progress Energy		<p>2a-2d.</p> <p>PE remains concerned with the present draft of TPL-001-2 regarding the presence or absence of footnotes in particular events. PE believes that, for all events in Table 1 except P0, any “No” designation in the “Non-Consequential Load Loss allowed” column should have Footnote 12 appended to it. Several events do append footnote 12 to a “No” answer, but several do not. PE does not see why certain events should be denied the use of Footnote 12 as long as Footnote 12 is worded in a manner such that the BES will not be adversely affected. PE has additional concerns regarding two Footnotes.</p> <p>Footnote 9 contains language regarding firm transmission service that is very similar to language presently under review in NERC Project 2010-11. PE feels that Footnote 9 should have had a statement at the end similar to that of Footnote 12, such as “Note: Firm Transmission Service is being decided in Project 2010-11. When that project is finalized, the resolution will be copied into Footnote 9.” Without such a statement, PE cannot understand why the Firm Transmission language in footnote (b) under Project 2010-11 is being reviewed, while it is apparently no longer being reviewed in Project 2006-02. Footnote 12 contains the following language as a place holder: “Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here.” PE has filed substantial comments on the footnote (b) issue in previous drafts, pointing out that disallowance of curtailment of non-consequential load is a local load issue and not a BES concern. PE therefore cannot make any positive determination as to whether the draft Standard, TPL-001-2, and its associated Table 1, will be a viable Standard until the language in Footnote 12 is resolved via Project 2010-11. Given the potential for unresolved and confusing issues regarding the parallel development of Project 2006-02 and 2010-11, PE encourages NERC to resolve all issues within Project 2010-11 before taking the draft Standard TPL-001-2 to ballot in Project 2006-02.</p>
Tucson Electric Power Company		<p>Table 1, P5 currently requires the study of “[d]elayed Fault Clearing due to the failure of a relay¹³ protecting the Faulted element to operate as designed”. As written, this requirement does not recognize the use of redundant relays for primary protection. In some cases side by side relays are used to provide primary fault tripping if one relay fails to operate. Per the requirement as stated, the redundant relay would provide no value in meeting this requirement. Please revise to acknowledge backup relays: “Single failure of a protection relay¹³ protecting the Faulted element to operate as designed, resulting in backup relay actions or Delayed Fault Clearing, for one of the following”.</p> <p>In Table 1, P2 and P3, the last column “Non-Consequential Load Loss Allowed” where the requirement “No¹²” appears, and in footnote 12, the standard as proposed does not allow for any Non-Consequential Load Loss. When the Non-Consequential Load Loss (footnote b) issue is clarified in Project 2010-11 this requirement may be changed. Therefore, if this proposed Standard is enforced before Project 2010-11 is completed, entities will be required to meet this No Non-Consequential Load Loss requirement without the exception allowed in the existing TPL-002-0, footnote “b”. This will require immediate redesigns to meet this</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 9 Comment
		<p>particular requirement. The unintended consequence could be that operators of local systems that are currently networked may opt to begin operation as radial systems, and future designs for local systems may be radial, at any voltage level. We suggest that the proposed footnote 12 include a provision to default to the existing footnote “b” in TPL-002-0 until Project 2010-11 is decided. Please revise footnote 12 to read, “Note: Non-Consequential Load Loss is being decided in Project 2010-11. When that project is finalized, the resolution will be copied here. In the interim, planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems. To prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power Transfers.”</p> <p>Timing of this project and project 2010-11 is critical. It would be very difficult to vote to approve the proposed TPL-001-2 prior to knowing the outcome of Project 2010-11 (footnote b issue). Non-Consequential Load Loss and curtailment of Firm Transmission Service should be allowed for loss of EHV BES elements for Category P4 and P5 events.</p>
New York Independent System Operator		There are two tables labeled “Table 1”. The extreme events table should be renamed “Table 2”.
MidAmerican Energy		Voting "no" - Footnote 6 - Further clarify the applicable shunt devices in Footnote 6 with this suggested text: 6. Requirements which are applicable to shunt devices, also apply to FACTS devices that are connected to ground, but not instrument voltage transformers or surge arresters
Southern California Edison Company		SCE supports the revised performance table.
Omaha Public Power District		Why is Footnote 12 used for some occurrences of the word "No" in the last column of Table 1 but not other occurrences of the word "No"?
Hydro One Networks Inc.		No selection boxes in this question. Yes, we support.
SERC Dynamics Review Subcommittee		Yes. The SERC DRS supports the revisions.
Duke Energy		We support the changes.

Organization	Yes or No	Question 9 Comment
South Carolina and Gas		Yes
Xcel Energy		<p>The defined term “Bus-tie Breaker” is not used per se anywhere in the Requirements or in Table 1. Suggest changing the description for Events P2-3, P2-4, P4 and P4-6 to use the term Bus-tie Breaker or non-Bus-tie Breaker, as applicable.</p> <p>Existing P5 event description needs improvement since the phrase “...failure of relay protecting the Faulted element to operate as designed...” reads awkwardly and also includes some superfluous verbiage that can be omitted. For example, isn’t “protecting the faulted element” the basic function of every protective relay? Also, isn’t “(failure) to operate as designed” inherent in the definition of Delayed Fault Clearing?</p> <p>Suggested P5 event description is: “Delayed Fault Clearing due to the operation failure of a primary protection relay¹³ when attempting to clear a fault on one of the following:”</p> <p>Footnote 13 – Delete “voltage (#27, #59)” since the under/over voltage relays are not called upon to provide the primary protection for fault clearing on Transmission elements.</p> <p>In Table 1 – Extreme Events – Stability – Items 2a-2d, change “Protection System failure” to “relay failure” to be consistent with changes in P5.</p> <p>Suggest modifying Event P4 description to be more consistent with Event P5 description by including Delayed Fault Clearing in the description in lieu of “Loss of multiple elements”. Suggested Event P4 description is: “Delayed Fault Clearing caused by a stuck non Bus-tie Breaker attempting to clear a fault on one of the following:”</p>

6. The SDT has revised the Measures based on industry comments to the initial ballot. If you do not support these changes, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

The SDT has made the following changes due to industry comments:

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using ~~the latest~~ data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, ~~any the~~ criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators, adjacent Transmission Planners, and any functional entity who has indicated a reliability need and that ~~the functional entity~~ Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

Data retention for R7 - The current, in force documentation for the agreement(s) on roles and responsibilities, as well as ~~all such~~ documentation for the agreements in force since the last compliance audit, in accordance with Requirement R7 and Measure M7.

Conforming changes were made to M6 and the data retention for R6/M6. Conforming changes were made to R1 to eliminate the phrase, “the latest.” The majority of respondents agree with the changes to the Measures and no other changes to the Measures have been made based on stakeholder comments.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 10 Comment
--------------	-----------	---------------------

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 10 Comment
Florida Reliability Coordinating Council, Inc - Transmission Working Group	No	It appears that there is a disagreement between R8 and M8, regarding public posting. We Agree with M8 posting option.
NorthWestern Energy (NWMT)	No	Measure M6 is too vague. It is unclear how to identify the conditions of Cascading, voltage instability, or uncontrolled islanding. The Glossary of Terms defines Cascading as “The uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.” Does the loss of system elements have to extend beyond the Control Area to be considered “Cascading”? Is there a Megawatt threshold that must be satisfied? Is there a time duration involved? Also, “cascading outages” needs to be defined. In addition, “voltage instability” and “uncontrolled islanding” should both be defined.
Lakeland Electric	No	please consider remove “the latest” from M1
Ameren	No	For measurements M3 and M4, there is some question as to what is to be provided as evidence of a study. Would the study results alone provide sufficient evidence, or does the entire powerflow, stability, or short circuit effort need to be documented in a formal study report? There are no measures for the creation and coordination of contingency lists that are to be developed in R3.4, R3.5, R4.4, and R4.5. Are these contingency lists required to be a documented part of the study?
MidAmerican Energy	No	Revise measures to be consistent with requirements. 1. R6 Delete “any”. The use of the word any in standards should not be allowed. 2. Revise the Planning Assessment definition to more explicitly apply to the BES and the TPL-001 requirements. We suggest text of: “Planning Assessment: Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies in the BES from the steady state and stability performance requirements set forth in the TPL-001 standard.” 3. R2.1.5 - We propose replacing the term ‘major Transmission’ with “BES” because BES is a well defined term, while the term, ‘major Transmission’, is not. 4. Add R2.3.1 - We suggest the addition of a R2.3.1 requirement to emulate the distinction between the requirement to perform a short circuit assessment and conduct required studies or analysis to support the assessment (e.g. R2.1/R2.1.1 and R2.2/R2.2.1). We propose wording such as, “Perform an analysis for at least one year in the Near Term Transmission Planning Horizon.” This requirement would set an expectation

Organization	Yes or No	Question 10 Comment
		<p>that an analysis should be conducted to at least one or more years in the near-term planning horizon, rather than imply that an analysis of all five years in the near-term planning horizon must be conducted.</p> <p>5. R2.7.2 - Delete 2.7.2. With regard to "include actions to resolve performance deficiencies identified in multiple sensitivity studies", mitigation plans should not be required for deficiencies found in multiple sensitivity studies because the conditions in some sensitivity studies are more extreme and less likely than base case conditions. Some of the sensitivity study conditions are not credible.</p> <p>6. R2.7.4 - We suggest that the wording of R2.7.4 be the same as R.2.8.2.</p> <p>7. R3.5 - We interpret that R3.5 requires the TP and PC to conduct an evaluation of possible actions to reduce the likelihood or impact of extreme events, which produce the more severe impacts, if cascading outages may occur. Does the drafting team intend for the TP and PC to fulfill this requirement for at least one event in each of the five categories (i.e. 3 steady state and 2 stability) or in each of the 21 categories/sub-categories (i.e. 14 steady state and 7 stability). Also, if the resulting cascading outages do not result in any overloads, under-voltages, voltage collapse, or loss of generator synchronization, then should the evaluation of possible actions to reduce likelihood or impact be required?</p> <p>8. R4.1.1 - We suggest that there should be some qualification of which generating units are referred to in this requirement. We propose that the requirement say, "No generating unit with a Point of Interconnection connected to the BES shall pull out of synchronism." For example, some utilities include smaller generation units that are connected at voltages below 100 kV and even down to distribution voltage in their base cases.</p> <p>9. R4.1.2 - We propose that the wording of this requirement be revised to reflect the same BES qualification of the generating unit that we noted in R4.1.1 above.</p> <p>10. R4.3.1 - This requirement refers to high speed reclosing and we presume that this is special high speed reclosing that is completed in several cycles, rather than the normal high speed reclosing that is completed in a number of seconds. We recommend that the term high speed reclosing be more clearly defined for this sub-requirement.</p> <p>11. R.4.3.2 - We suggest qualifying which generating units to consider and which voltage limits to simulate with revised wording like, "Trip generating units that are connected to the BES when actual or assumed minimum generator transient voltage limits are known and simulations show voltages may fall below the voltage limit. If assumed voltage limits are used, then they should be included in the assessment". The requirement should not apply to all relevant generating units until one of the MOD standards requires all Generator Owners to provide their minimum generating unit voltage limits to the TP and PC. If the wording of R4.3.2 must be different from its counterpart, R3.3.2, then please explain the reasons for any differences.</p> <p>12. R5 - This requirement should allow the applicable entity (such as the TOP / TO) to define a "Post-Contingency Voltage Deviation" as this criteria is not used widely enough in the industry to be a well</p>

7. The SDT has revised the Requirement R8 VSL based on industry comments to the initial ballot. If you do not support these changes, please specify why you disagree and include specific alternative language to resolve your concern.

Summary Consideration:

The SDT made the following clarification due to industry comments:

4.3.1, bullet #1: Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

The VSL was not changed as the majority response was that the industry is in general agreement with the VSL.

The SDT did not pose questions for items that were not redlined, i.e., changed, in this posting since those items not redlined were considered by the SDT as sufficiently vetted by the industry through the various phases of the project to date. However, the SDT has reviewed all comments regardless of whether specific questions were asked and has considered the comments.

Organization	Yes or No	Question 11 Comment
Northeast Power Coordinating Council Consolidated Edison Co. of New York, Inc.	No	<p>Requirement 8 is an administrative burden to TPs and PCs that adds no value to Bulk Power System reliability. PCs should be including TPs, neighboring PCs and interested parties in its planning processes when developing the Planning Assessments. Therefore, the inclusion of a set of VSLs for Requirement 8 is unnecessary. Should the VSLs for Requirement 8 remain, Requirement 8.1 should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response as follows: If a recipient of the planning assessment final results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments. If Requirement 8 and 8.1 are retained, they should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response and there should be a limit on the comment period as follows: If a recipient of the planning assessment final results provides documented comments on the results within 90 days of receipt, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments.</p> <p>Other comments not addressed by this Comment Form as follows: Section 3.3 - The last sentence of 3.3.1 should be removed. This is addressed in PRC-023. Line ratings are addressed in PRC-023. PRC-023 requires coordination with the Reliability Coordinator. Remove "Tripping of Transmission elements where relay loadability limits are exceeded."</p> <p>Section 4.3 - High speed reclosing is not defined, and to help eliminate any confusion that it may introduce</p>

Organization	Yes or No	Question 11 Comment
		<p>into the standard it will be worthwhile for the SDT to define this term.</p> <p>Several specific examples from previous comments on sensitivity analysis and guidance for base case assumptions: The requirements for sensitivity analysis already address issues going beyond what is expected to meet reliability requirements.</p> <p>Requiring extreme event analysis is requiring two layers of event analysis beyond what is required and there is no requirement for corrective action if anything is identified.</p> <p>The standard is referring to requirements for sensitivity and other issues without a reference to base assumptions. The standard must describe base assumptions. To define a sensitivity condition, NERC must define base assumptions.</p> <p>As for allowing con-consequential load loss for Categories P1 through P5, suggest approval at the Regional level, with a concept of allowing it in a “local area” that does not impact BPS reliability.</p> <p>All references to 300 kV in document should be replaced with EHV (for example in the Introduction, Section 5).The first phrase of Note 3 on p. 14 should be revised as follows: “Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as those representing the backbone of the System, generally at voltage greater than 300 kV, and high voltage (HV) Facilities defined as those not representing the backbone of the System, as determined by the Planning Coordinator and approved by Regional Entity.”</p>
IRC Standards Review Committee	No	<p>(AESO is not a party to the following comments since its VSLs are set by the Alberta regulatory authority.)Requirement 8 is an administrative burden to TPs and PCs that adds no value to reliability. PCs should be including TPs, neighboring PCs and interested parties in its planning processes when developing the Planning Assessments. Therefore, the inclusion of a set of VSLs for Requirement 8 is unnecessary.Should the SDT decide to leave the VSLs for Requirement 8, Requirement 8.1 should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response as follows: 8.1 If a recipient of the planning assessment final results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments.For a Planning Coordinator (PC) who distributes the Planning Assessment to many different entities (to adjacent PCs, TPs, and other functional entities), a concern regarding the Requirement R8 VSL is that it is overly restrictive to apply a violation for failing to distribute the results of its Planning Assessment to only one PC, TP, or functional entity (and to apply a High VSL for failing to distribute to more than one entity), particularly since an entity’s contact is subject to change over time, and since Measure M8 allows for publicly posting the results of its Planning Assessment to its website. Should the SDT decide to include the VSLs for Requirement 8, we would recommend revising to use a percentage approach rather than applying a violation to a Planning</p>

Organization	Yes or No	Question 11 Comment
		<p>Coordinator who fails to provide the results of its Planning Assessment to one PC, TP, or other functional entity (or applying a High VSL for failing to distribute to more than one entity.) Recommend applying a similar percentage approach to the VSLs drafted by NERC Staff for Project #2007-23 VSLs (e.g., for FAC-013-1) to be considered for the TPL-001-2 R8 VSLs. For example,</p> <ul style="list-style-type: none"> o Lower VSL: The responsible entity failed to provide the Planning Assessment final results to 5% or less of the required entities. o Moderate VSL: The responsible entity failed to provide the Planning Assessment final results to more than 5% up to (and including) 10% of the required entities. o High VSL: The responsible entity failed to provide the Planning Assessment final results to more than 10% up to (and including) 15% of the required entities. o Severe VSL: The responsible entity failed to provide the Planning Assessment final results to more than 15% of the required entities OR [the existing language for the Severe VSL].Explanation: The VSLs were modified for consistency with other standards and VSLs.Reference: Link to VSLs drafted by NERC Staff for Project #2007-23 VSLs (e.g., for FAC-013-1):http://www.nerc.com/docs/standards/sar/Staff_Proposed_VSLs_2010July27.pdf
Southern Company	No	<p>We wish to make a comment on R4.3.1: it appears that this requires stability simulations of both successful and unsuccessful high-speed reclosing for all contingency simulations regardless of whether high-speed reclosing is used on the faulted line. We suggest the following wording be used to replace the first bullet: “Successful high-speed reclosing and unsuccessful high-speed reclosing onto a fault, where such reclosing is applied, and where such additional simulations are deemed appropriate by the PC or TP.”</p> <p>Also, we wish to make a comment on footnote #13 of Table 1. 13. Applies to any of the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, & 67), voltage (#27 & 59), directional (#32 & 67), and associated tripping (#86 & 94) relays.</p>
Florida Reliability Coordinating Council, Inc - Transmission Working Group	No	<p>The requirement to distribute the Planning Assessment should be more flexible and allow for making the Planning Assessment available, such that those entities that desire the information can have it readily available. R8 should be modified to replace distribute with “make available:”, so the new requirement would read as follows: Each Planning Coordinator and Transmission Planner shall make available its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.</p>
PacifiCorp	No	<p>The language for Requirement R8 is ambiguous with regard to which adjacent entities must request in writing the results of the Planning Assessment. The language should be clarified to read: “Upon request made in</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 11 Comment
		writing, each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators, adjacent Transmission Planners, and any other functional entity that has a reliability related need.” The Requirement R8 VSL language should also be revised accordingly.
ReliabilityFirst	No	<p>TPL-001-2 Draft 5 is much better than Draft 4. There is still one significant concern, that I do not believe the drafting team adequately addressed. It is unclear as to what “Planning Assessment results” and “results of its Planning Assessment” entail. The Draft 5 response that “Planning Assessment” is a defined term does not fully address this concern. “Planning Assessment results” or “results of its Planning Assessment” is not necessarily the same thing as “Planning Assessment”. As written, “Planning Assessment results” or “results of its Planning Assessment” could be anything from a single sentence, to a few brief high level paragraphs, to a detailed and technically complete Planning Assessment. The Standard needs to more clearly state what is required in the report to other entities. Based on the drafting team response in Draft 4, it seems that replacement of “Planning Assessment results” or “results of its Planning Assessment” with the term “Planning Assessment” or “its Planning Assessment” would be appropriate.</p> <p>Violation Severity Levels: R8 The failure to provide documented responses to documented comments to “Planning Assessment results” is deemed to be a higher severity level than failing to distribute “results of its Planning Assessment”. Failure to distribute denies functional entities an opportunity to comment, and could prevent coordinated planning, and thus should be deemed to be more severe than failing to provide documented responses to documented comments.</p>
Lakeland Electric	No	The requirement to distribute the Planning Assessment should be more flexible and allow for making the Planning Assessment available, such that those entities that desire the information can have it readily available. R8 should be modified as follows: Each Planning Coordinator and Transmission Planner shall make available its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners and to any functional entity that indicates a reliability related need for the Planning Assessment results.
Orlando Utilities Commission	No	R8 should require that the PC and TP make available its planning assessment results when requested, rather than requiring the preemptive transmittal. There is no reliability purpose served by providing unsolicited information.
US Bureau of Reclamation	No	The language implies that the responsible entity may choose to not distribute it if it feels the entity making the request does not have a "reliability related need". It is not clear why that distinction is being made?
California ISO	No	Requirement 8 is an administrative burden to TPs and PCs that adds no value to reliability. PCs should be including TPs, neighboring PCs and interested parties in its planning processes when developing the

Organization	Yes or No	Question 11 Comment
		<p>Planning Assessments. Therefore, the inclusion of a set of VSLs for Requirement 8 is unnecessary. Should the SDT decide to leave the VSLs for Requirement 8, Requirement 8.1 should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response as follows:</p> <p>8.1 If a recipient of the planning assessment final results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments. For a Planning Coordinator (PC) who distributes the Planning Assessment to many different entities (to adjacent PCs, TPs, and other functional entities), a concern regarding the Requirement R8 VSL is that it is overly restrictive to apply a violation for failing to distribute the results of its Planning Assessment to only one PC, TP, or functional entity (and to apply a High VSL for failing to distribute to more than one entity), particularly since an entity's contact is subject to change over time, and since Measure M8 allows for publicly posting the results of its Planning Assessment to its website. Should the SDT decide to include the VSLs for Requirement 8, would recommend revising to use a percentage approach rather than applying a violation to a Planning Coordinator who fails to provide the results of its Planning Assessment to one PC, TP, or other functional entity (or applying a High VSL for failing to distribute to more than one entity.) Recommend applying a similar percentage approach to the VSLs drafted by NERC Staff for Project #2007-23 VSLs (e.g., for FAC-013-1) to be considered for the TPL-001-2 R8 VSLs. For example,</p> <ul style="list-style-type: none"> o Lower VSL: The responsible entity failed to provide the Planning Assessment final results to 5% or less of the required entities. o Moderate VSL: The responsible entity failed to provide the Planning Assessment final results to more than 5% up to (and including) 10% of the required entities. o High VSL: The responsible entity failed to provide the Planning Assessment final results to more than 10% up to (and including) 15% of the required entities. o Severe VSL: The responsible entity failed to provide the Planning Assessment final results to more than 15% of the required entities OR [the existing language for the Severe VSL]. <p>Explanation: The VSLs were modified for consistency with other standards and VSLs. Reference: Link to VSLs drafted by NERC Staff for Project #2007-23 VSLs (e.g., for FAC-013-1): http://www.nerc.com/docs/standards/sar/Staff_Proposed_VSLs_2010July27.pdf</p>
Ameren	No	<p>The sharing issues of requirement R8 are still not clear, therefore the R8 VSL is not clear. It is not clear if the intent of the SDT is for the PC to share the assessments with PCs and TPs are to share the assessments with TPs, or whether the intent is for the TP to share its assessments with its PC. Will posting the assessment to a secure web-site meet the intent of the requirement?</p> <p>Although the comment form is not designed to allow for such, we need to comment on R4.3.1: As written, it appears that this requires stability simulations of both successful and unsuccessful high-speed reclosing for all contingency simulations, regardless of whether high-speed reclosing is actually implemented. A suggested wording change for the first bullet: "Successful high-speed reclosing and unsuccessful high-speed reclosing onto a fault, where such reclosing is applied, and where such additional simulations are deemed appropriate by the PC or TP."</p>

Organization	Yes or No	Question 11 Comment
		<p>Another comment needs to be made regarding the stability extreme event table: Changes were made in planning event P5 to concentrate on specific relay failures. The same changes need to be made for stability extreme events 2a, 2b, 2c, and 2d. The proposed standard will significantly increase the amount of work required to develop more detailed and complex system models, to perform and document the engineering studies to meet the performance requirements, and to develop the assessments necessary for compliance. All of these increased engineering activities are perceived to provide marginal benefit to the reliability of the bulk electric system, but will require significant increases in manpower across the industry. Further, the manpower is presently not available to develop these more detailed models and to perform these studies with any reasonable assuredness. It will be a continuing challenge to the industry to obtain and keep the engineering talent needed to perform these compliance activities for such marginal benefits.</p>
<p>Central Maine Power Company New York State Electric & Gas Corp</p>	<p>No</p>	<p>Requirement 8 is an administrative burden to TPs and PCs that adds no value to reliability. PCs should be including TPs, neighboring PCs and interested parties in its planning processes when developing the Planning Assessments. Therefore, the inclusion of a set of VSLs for Requirement 8 is unnecessary. Furthermore, the requirement lacks a specified time frame to receive comments, thereby implying that TPs and PCs would be required to reply to comments forever following the finalization of a Planning Assessment. The NYISO proposes a limit of six months. Should the SDT decide to leave the VSLs for Requirement 8, Requirement 8.1 should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response as follows: If a recipient of the planning assessment final results provides documented comments on the results within 180 calendar days of the issuance of those final results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments.</p> <p>We also have other comments not addressed by this Comment Form as follows - Section 2.7, Section 3.3, Section 4.3, and overall: Section 2.7 requires that Corrective Action Plans are included in each Planning Assessment and states "Such actions may include..." followed by a list of actions. Restricting allowable actions, and excluding runback/tripping of HVDC would have a direct impact on multiple existing facilities in New York and would adversely impact the reliability planning of the NYCA. Runback/tripping of HVDC must be added to the list.</p> <p>Section 3.3 - We feel that the last sentence of 3.3.1 should be removed. This is handled by PRC-023. Line ratings are addressed by PRC-023. PRC-023 requires coordination with the Reliability Coordinator. Remove "Tripping of Transmission elements where relay loadability limits are exceeded."</p> <p>Section 4.3 - High speed reclosing is not defined. Overall - We have previously made comments which have not been addressed in the current version of the proposed standard. Support for the standard can at most be limited without addressing comments.</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 11 Comment
		<p>We have previously commented on sensitivity analysis and guidance for base case assumptions.</p> <p>Also, extreme event analysis should not be mandated in this standard as no corrective action is required. The requirements for sensitivity analysis already address issues going beyond what is expected to meet reliability requirements. Requiring extreme event analysis is requiring two layers of event analysis beyond what is required, and there is no requirement for corrective action if anything is identified. The standard is referring to requirements for sensitivity and other issues without a reference to base assumptions. The standard must describe base assumptions. To define a sensitivity condition, NERC must define base assumptions.</p>
New York Independent System Operator	No	<p>Requirement 8 is an administrative burden to TPs and PCs that adds no value to reliability. PCs should be including TPs, neighboring PCs and interested parties in its planning processes when developing the Planning Assessments. Therefore, the inclusion of a set of VSLs for Requirement 8 is unnecessary. Furthermore, the requirement lacks a specified time frame to receive comments, thereby implying that TPs and PCs would be required to reply to comments forever following the finalization of a Planning Assessment. The NYISO proposes a limit of six months. Should the SDT decide to leave the VSLs for Requirement 8, Requirement 8.1 should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response as follows: If a recipient of the planning assessment final results provides documented comments on the results within 180 calendar days of the issuance of those final results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments.</p>
NERC staff	Yes	NERC staff supports the changes to the VSL for Requirement R8.
SERC Planning Standards Subcommittee	Yes	<p>Comments: We wish to make a comment on R4.3.1: it appears that this requires stability simulations of both successful and unsuccessful high-speed reclosing for all contingency simulations regardless of whether high-speed reclosing is used on the faulted line. We suggest the following wording be used to replace the first bullet: "Successful high-speed reclosing and unsuccessful high-speed reclosing onto a fault, where such reclosing is applied, and where such additional simulations are deemed appropriate by the PC or TP."</p> <p>We wish to make a comment on the stability extreme event table: Changes were made in planning event P5 to narrow the focus to specific relay failures. The same changes are needed for stability extreme event 2a, 2b, 2c, and 2d.</p>
Hydro One Networks Inc.	Yes	Requirement 8 is an administrative burden and adds little or no value to the BPS reliability. Therefore, the inclusion of a set of VSLs for Requirement 8 is unnecessary.
SERC Dynamics Review	Yes	We wish to make a comment on R4.3.1: it appears that this requires stability simulations of both successful

Organization	Yes or No	Question 11 Comment
Subcommittee		<p>and unsuccessful high-speed reclosing for all contingency simulations regardless of whether high-speed reclosing is used on the faulted line. We suggest the following wording be used to replace the first bullet: "Successful high-speed reclosing and unsuccessful high-speed reclosing onto a fault, where such reclosing is applied." We wish to make a comment on the stability extreme event table: Changes were made in planning event P5 to narrow the focus to specific relay failures. The same changes are needed for stability extreme event 2a, 2b, 2c, and 2d.</p>
MRO's NERC Standards Review Subcommittee	Yes	<p>Other Comments:</p> <ol style="list-style-type: none"> 1. How are backup relays handled (TPL-002-0, R1.3.10 & TPL-001-2 R1 & P5)? What does FERC construe as normal system for a protection system. The TPL-001-2 R1 & P5, this standard doesn't appear to address primary protection and how this handled. 2. Revise the Planning Assessment definition to more explicitly apply to the BES and the TPL-001 requirements. We suggest text of: "Planning Assessment: Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies in the BES from the steady state and stability performance requirements set forth in the TPL-001 standard." 3. R2.1.5 - We propose replacing the term 'major Transmission' with "BES" because BES is a well defined term, while the term, 'major Transmission', is not. 4. Add R2.3.1 - We suggest the addition of a R2.3.1 requirement to emulate the distinction between the requirement to perform a short circuit assessment and conduct required studies or analysis to support the assessment (e.g. R2.1/R2.1.1 and R2.2/R2.2.1). We propose wording such as, "Perform an analysis for at least one year in the Near Term Transmission Planning Horizon." This requirement would set an expectation that an analysis should be conducted to at least one or more years in the near-term planning horizon, rather than imply that an analysis of all five years in the near-term planning horizon must be conducted. 5. R2.7.4 - We suggest that the wording of R2.7.4 be the same as R.2.8.2. Otherwise, we propose that R2.7.4 and R2.8.2 be revised with wording like, ". . . implementation status of identified Corrective Action Plans for System Facilities and Operating Procedures." to clarify that the identified system facilities and operating procedures refer only to those that were in the previous year's Corrective Action Plans. 6. R3.3.1 - The term of 'controls' is ambiguous and not defined, unlike the term, 'Protection Systems', which is defined. Therefore, we suggest that this item be defined or more clearly described to avoid the risk of different and possibly contradictory interpretations by TPs, PCs, and auditors. 7. R3.3.1, bullet #1 - We suggest qualifying which generating units to consider and which voltage limits to simulate with revised wording like, "Trip generating units that are connected to the BES when actual or assumed minimum generator steady state or ride through voltage limits are known and simulations show voltages may fall below the voltage limit. If assumed voltage limits are used, then they should be included in the assessment". The requirement should not apply to all relevant generating units until one of the MOD

Organization	Yes or No	Question 11 Comment
		<p>standards requires all Generator Owners to provide their minimum generating unit voltage limits to the TP and PC. If the wording of R3.3.1 bullet #1 must be different from its counterpart, R4.3.1 bullet #2, then please explain the reasons for any differences.</p> <p>8. R3.4.1 - Compliance with the requirement “to coordinate” is problematic and non-measurable We suggest replacing it with the requirement “to communicate”.</p> <p>9. R3.5 - We interpret that R3.5 requires the TP and PC to conduct an evaluation of possible actions to reduce the likelihood or impact of extreme events, which produce the more severe impacts, if cascading outages may occur. Does the drafting team intend for the TP and PC to fulfill this requirement for at least one event in each of the five categories (i.e. 3 steady state and 2 stability) or in each of the 21 categories/sub-categories (i.e. 14 steady state and 7 stability). Also, if the resulting cascading outages do not result in any overloads, under-voltages, voltage collapse, or loss of generator synchronization, then should the evaluation of possible actions to reduce likelihood or impact be required?</p> <p>10. R4.1.1 - We suggest that there should be some qualification of which generating units are referred to in this requirement. We propose that the requirement say, “No generating unit connected to the BES shall pull out of synchronism.” For example, some utilities include smaller generation units that are connected at voltages below 100 kV and even down to distribution voltage in their base cases.</p> <p>11. R4.1.2 - We propose that the wording of this requirement be revised to reflect the same BES qualification of the generating unit that we noted in R4.1.1 above.</p> <p>12. R4.3.1 - This requirement refers to high speed reclosing and we presume that this is special high speed reclosing that is completed in several cycles, rather than the normal high speed reclosing that is completed in a number of seconds. We recommend that the term high speed reclosing be more clearly defined for this sub-requirement.</p> <p>13. R5 - This requirement should remove the criterion item, “post-Contingency voltage deviation”, because this criterion is not used widely enough in the industry to be well established criterion.</p> <p>14. R8 - This requirement should be revised to limit the need to provide the Planning Assessment as follows “adjacent Planning Coordinators and adjacent Transmission Planners and to any registered functional entity...” This suggestion is added to the requirement to clarify that the word adjacent also applies to Transmission Planners and to clarify that the functional entity must be registered in order for the entity to be applicable to the requirement.</p>
TVA Transmission Planning & Compliance	Yes	<p>Additional TVA comments:TVA wishes to make a comment on R4.3.1: it appears that this requires stability simulations of both successful and unsuccessful high-speed reclosing for all contingency simulations. Does high speed reclosing occur in less than 60 cycles or 60 seconds? If a utility does not have reclosing on a</p>

Organization	Yes or No	Question 11 Comment
		<p>transmission line - then must the utility still perform stability studies assuming that there is reclosing? TVA suggests the following wording be used to replace the first bullet: "Successful high-speed reclosing and unsuccessful high-speed reclosing onto a fault, where such reclosing is applied, and where such additional simulations are deemed appropriate by the PC or TP."</p> <p>In R4.1.1, TVA is concerned that no generating unit shall pull out of synchronism in a local area only (thus not impacting the overall reliability of the BES) for Planning Event P1, while the standard does allow generator runback/tripping for the same event. Thus the generating unit may be tripped by a special protection scheme - but may not be tripped by an out of step relay. TVA believes that out of step relaying should be allowed for this unit tripping as long as this does not affect the overall reliability of the BES.</p>
South Carolina and Gas	Yes	<p>We wish to make a comment on the revisions to R4.3.1. We believe that the analysis of both successful and unsuccessful high speed reclosing for all cases is not justified and should be left to the discretion of the Transmission Planner.</p>
ISO New England Inc.	Yes	<p>Requirement 8 and 8.1, should be revised to reflect that comments only to the final Assessment (not drafts developed during a process) need a response and there should be a limit on the comment period as follows: If a recipient of the planning assessment final results provides documented comments on the results within 90 days of receipt, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments.</p> <p>We have other comments not addressed by this Comment Form as follows - Sections 2.7, 3.3, 4.3 and overall. R2.7 requires that Corrective Action Plans are included in each Planning Assessment and states "Such actions may include..." followed by a list of actions. Runback/tripping of HVDC should be added to the list.</p> <p>Section 3.3 - We feel that the last sentence of 3.3.1 should be removed. This is handled by PRC-023. Line ratings are addressed by PRC-023. PRC-023 requires coordination with the Reliability Coordinator. Remove "Tripping of Transmission elements where relay loadability limits are exceeded."</p> <p>Section 4.3 - High speed reclosing needs to be defined.</p>
Hydro-Quebec TransEnergie	Yes	<p>o All references to 300 kV in document should be replaced with EHV (In the introduction, section 5) o The first phrase of Note 3 on p 14 should be revised as follows: "Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as those representing the backbone of the System, generally at voltage greater than 300 kV, and high voltage (HV) Facilities defined as those not representing the backbone of the System, as determined by the Planning Coordinator and approved by Regional Entity."</p>

Consideration of Comments from Informal Comment Period – Assess Transmission Future Needs – Project 2006-02

Organization	Yes or No	Question 11 Comment
National Grid	Yes	<p>Other Comments:Section 3.3 - We feel that the last sentence of 3.3.1 should be removed. This is handled by PRC-023. Line ratings are addressed by PRC-023. PRC-023 requires coordination with the Reliability Coordinator. Remove “Tripping of Transmission elements where relay loadability limits are exceeded.”</p> <p>Section 4.3 - High speed reclosing is not defined. We have previously commented on sensitivity analysis and guidance for base case assumptions. Also, extreme event analysis should not be mandated in this standard as no corrective action is required.</p>
Tri-State Generation & Transmission	Yes	<p>None regarding R8.</p> <p>The following comments refer to parts of the proposed standard for which no questions are asked.R4, Part 4.1.2: The response to our previous comment indicated that our description was for a system Stability issue. R4 is addressing system Stability and we believe the comment still applies and that it was not answered in the response. We have two issues with 4.1.2: Sometimes out-of-step (loss of generator synchronism) is better mitigated through islanding by tripping transmission rather than by tripping generators; the second point is that the ability of present modeling programs does not include the capability to model all types of impedance relays and their associated OOS blocking and tripping capabilities that are available.</p> <p>R4, Part 4.3.1: The third bullet implies that all impedance relays (and perhaps others) will need to be modeled in the stability databases. We question whether the existing simulation programs can accommodate this large magnitude of data inclusion and whether there is any benefit to BES reliability. Certainly using generic models rather than actual models would be of no benefit. We recommend changing the third bullet to “Evaluation of Protection System behavior when transient power swings are detected or predicted to have impedance characteristics that may approach relay operating characteristics.”</p>
Northeast Utilities	Yes	<p>No comments on Question 7.Other Comments: As detailed below, NU has other comments that are not addressed by this Comment Form as follows - Section 3.3, Section 4.3, Non-Consequential Load Loss as referenced in the events Table 1 and studies using extreme event contingencies. Section 3.3 - NU believes that the last sentence of Part 3.3.1 should be removed since this is handled by PRC-023. Line ratings are addressed by PRC-023 which requires coordination with the Reliability Coordinator. NU suggests the removal of the following sentence: “Tripping of Transmission elements where relay loadability limits are exceeded.”</p> <p>Section 4.3 - High speed reclosing is not defined and to help eliminate any confusion that it may introduce into the standard it will be worthwhile for the SDT to define this term. Non-Consequential Load Loss - Depending upon the resolution of “Project 2010-11, TPL Table 1, Footnote b” NU may have additional comments regarding this issue.</p> <p>Studies Using Extreme Event Contingencies: The requirements for sensitivity analysis already address issues</p>

Organization	Yes or No	Question 11 Comment
		going beyond what is expected to meet the reliability requirements of the standard. Therefore, requiring extreme event analysis is requiring two layers of event analysis beyond what is required and there is no requirement for corrective action if a concern is identified.
NBSO	Yes	NBSO suggests considering rewording the VSL so that they address the failure to distribute the final results of planning assessments.
ERCOT ISO	Yes	<p>ADDITIONAL COMMENTS: Short circuit analysis (R2.3 and R2.8) should only be applicable to TPs. Fault duty issues are typically local in nature and it would be an overlap for PCs to perform this same analysis done by the local Transmission Planner.</p> <p>Furthermore, R7 should be deleted and the responsibilities of each entity should be explicitly stated within the specific requirements.</p> <p>Previous Comment Unaddressed : Requirement 2.6.2: Reads as if a change is being made to an existing study. It is confusing. Possibly restate: "2.6.2 For steady state, short circuit, or stability analysis: previous studies can be used only if a material change to the system has not occurred or if a change that did occur does not impact the study area."</p> <p>R4.1.2 - Planning Coordinators do not perform protection coordination nor do they have access to the relay settings information required to do this analysis. This requirement should apply to Transmission Planners only because they perform system protection. The substantive scope of the standard is relative to Long-Term Transmission Planning Horizon and Near-Term Transmission Planning Horizon. The Purpose section is described in terms of the "planning horizon" generally. It may be worthwhile aligning the two to mitigate the potential for any confusion.</p> <p>ERCOT proposes the following revisions to the Purpose section: 3.Purpose: Establish Transmission system planning performance requirements within the relevant planning horizon (i.e. Long-Term or Near-Term) to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies</p> <p>.In addition, the "Time Horizon" for the Standard is "Long-Term Planning". Obviously, this necessarily encompasses both Long-Term and Near-Term Transmission Planning Horizons. However, the scope of the Long-Term Planning time horizon is not readily apparent. ERCOT recommends appropriate revisions that clearly define the applicable time horizons.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

The Assess Transmission Future Needs and Develop Transmission Plans Drafting Team thanks all commenters who submitted comments on the 6th draft of the TPL-001-2 standard for Assess Transmission Future Needs (Project 2006-02). These standards and associated documents were posted for a 45-day public comment period from April 18, 2011 through May 31, 2011. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. There were 43 sets of comments, including comments from approximately 78 different people and approximately 69 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

No changes were made to the text of any Requirement. The SDT made several changes in response to comments submitted during the formal comment period and successive ballot that ended May 31, 2011.

- The 5th and 6th bullets of the Data Retention section to make the language in the data retention statements consistent with the language in the requirements.
- The third part of the Severe VSL for Requirement R1 to make the language consistent with the requirement.
- The VSL for Requirement R8 to make the language consistent with the language in the requirement.
- The Effective Date section of the Implementation Plan to make the language consistent with the language in the Effective Date section in the proposed TPL-001-2.
- The bullets in Requirement R3, Part 3.3.1 were replaced with numbers because the bullets were inconsistent with NERC's protocol on the use of bullets in Requirements.
- The bullets in Requirement R4, Part 4.3.1 were replaced with numbers because the bullets were inconsistent with NERC's protocol on the use of bullets in Requirements.

The SDT is requesting that this project be moved to the recirculation ballot stage.

All comments submitted may be reviewed in their original format on the standard's project page:

<http://www.nerc.com/filez/standards/Assess-Transmission-Future-Needs.html>

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.¹

¹ The appeals process is in the Reliability Standards Development Procedures:
<http://www.nerc.com/standards/newstandardsprocess.html>.

Index to Questions, Comments, and Responses

1. The SDT has made revisions to the requirements language of TPL-001-2 based on industry comments and the Quality Review. Do you agree with these changes? If you do not support these changes or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments with clear indications as to which requirement you are commenting on. 10
2. The SDT has made revisions to the VRF and VSL of TPL-001-2 which will be part of a non-binding poll with this posting based on industry comments and the Quality Review. Do you agree with these changes? If you do not support these changes or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. 39
3. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here. 54

1. **The SDT has made revisions to the requirements language of TPL-001-2 based on industry comments and the Quality Review. Do you agree with these changes? If you do not support these changes or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments with clear indications as to which requirement you are commenting on.**

Summary Consideration: Several commenters stated that Requirement R1, Part 1.1.5 should not include interchange because interchange introduces economic considerations into a Reliability Standard. The SDT explained that the requirement is to include known commitments for interchange and therefore the requirement is not for economic purposes, but rather planning to meet obligations.

A number of commenters stated that they believed that there was an inconsistency between Requirement R2, Parts 2.1 and 2.2, since qualified studies were not allowed for the Long-Term Transmission Planning Horizon case. The SDT believes that the requirement to conduct the annual study on one of the study years in the Long-Term Transmission Planning Horizon ensures that the planner conducts a new study annually to evaluate the System improvement needs in the Long-Term Transmission Planning Horizon, even if they utilize qualified past studies for the Near-Term Transmission Planning Horizon cases.

Several commenters stated that they believed that Requirement R2, Part 2.1.5 was ambiguous since it was not clear that the planner did not have to include multiple outages of long lead time components simultaneously. The SDT explained that Requirement R2, Part 2.1.5 does not require simultaneous outages of multiple long lead time components.

Some commenters expressed concerns with Requirement R2, Part 2.4.1 since they were concerned with the ability for planners to adequately model the dynamic behavior of Load. The SDT explained that since it is important to correctly model the characteristics of the Load, it believes that the requirement to represent the dynamic behavior of the Load is needed to ensure BES reliability.

A number of commenters expressed concern that Requirement R7 was administrative and was not required. The SDT explained that it believes that the requirement is necessary to ensure that there are no gaps created between the Transmission Planners and the Planning Coordinators when they determine their individual responsibilities.

Several commenters stated that they had concerns with Requirement R8. These concerns are that the requirements create excessive work and should include time limits on requesting the Planning Assessment, are ambiguous, and should include the ability to post the Planning Assessment. The SDT explained that the requirements are only to distribute the Planning Assessment, which should not require a large amount of work, and the requirements are clear that the planners must distribute to adjacent Transmission Planners and Planning Coordinators and others with a reliability need. The SDT further explained that posting the Planning Assessment could meet the requirement to distribute.

Several commenters stated that they believed that Table 1, P2-1 was inconsistent with Footnote 7. The SDT explained that Footnote 7 was included to clarify that “Opening a line section without a fault” could include, but does not always, creating a radial line section with Load and that the planner must evaluate this situation as a part of P2-1.

A number of commenters expressed concern that Footnote 12 was not appropriate or that this standard should be delayed until FERC approved TPL-002-1 Footnote ‘b’. The SDT explained that Footnote 12 was consistent with language in the recent NERC Board of Trustees approved TPL-002-1 Footnote ‘b’ and that this standard should not be delayed until FERC rules on the other standard.

No changes were made to requirements due to industry comments to question 1. However changes were made to the wording of the Implementation Plan to make it consistent with the language in the Effective Date section of the standard. Also, the language in the data retention section was changed for bullets five and six to make it consistent with the language in the requirements – no changes were made to the timeframe for data retention.

DR, 5th bullet: The documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and transient voltage response since the last compliance audit in accordance with Requirement R5 and Measure M5.

DR, 6th bullet: The documentation specifying the criteria or methodology utilized in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding in support of its Planning Assessments since the last compliance audit in accordance with Requirement R6 and Measure M6.

Organization	Yes / No	Question 1 Comment
Lower Colorado River Authority	Ballot Comment	<p>1. R2 (2.5): The requirement for stability assessment in years 6-10 should be limited for new generation interconnections or for planned major transmission system improvements that have regional impact. The standard should clarify the ‘material changes’ that would necessitate stability planning assessments and documentation.</p> <p>2. R8 requirement to distribute all Planning Assessment results to adjacent PCs and TPs are excessive and cumbersome. Regarding R8, LCRA TSC suggests the following language: Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners in accordance with the overseeing Reliability Coordinator requirements. Any functional entity that has a reliability related need and submits a written request for the Planning Assessment results, the Transmission Planner and Planning Coordinator shall provide the latest Planning Assessment results within 30 days of such request.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
<p>Response: For Requirement R2, Part 2.5, the SDT believes it is important to evaluate Stability when the planners are evaluating new generation additions or changes which can be more than 5 years in the future, as required in NERC Standard FAC-001-0. The SDT discussed defining 'material change' but did not believe that such a definition was appropriate in a continent-wide standard. With the wide variety in sizes and types of systems, the number of parameters that need to be considered, etc., there are too many variables involved. No change made.</p> <p>For Requirement R8, the SDT disagrees that the requirement is excessive and cumbersome and did not make the suggested change. In addition, the proposed language would place requirements on the Reliability Coordinators, who are not included in the Applicability for this standard, and they should not be involved in determining the extent of the distribution of the Planning Assessments.</p>		
Florida Municipal Power Agency	Ballot Comment	<p>FMPA has minor comments to help improve the clarity of the standard. R7 is not needed and administrative in nature. Instead it should say that an entity can use as evidence another entity's study, but not in the requirement and rather in the measures.</p> <p>R8 is ambiguous, does the requirement require submitting the Planning Assessment only after receiving a written request, or automatic distribution to neighboring PCs and TPs without a written request, and to others with a reliability related need following a written request?</p> <p>Table 1, under first heading of "Steady State and Stability", bullet c should be removed since it is duplicative of the standard, and not entirely consistent with the standard (e.g., open to interpretation whereas the standard better clarifies how to study protection system operation)</p>
<p>Response: Requirement R7 ensures that there are no gaps between Transmission Planners or the Planning Coordinators that may cause reliability concerns. No change made.</p> <p>Requirement R8 requires the automatic distribution to neighboring Planning Coordinators and Transmission Planners without a written request and to others with a reliability related need following a written request. The SDT believes this is an important considerations and not ambiguous. No change made.</p> <p>Table 1, bullet c under first heading, is not in conflict with the requirements. The SDT decided to include additional details in Table 1 so that it would have the basic information necessary for the planner to develop the simulations for their studies without always referring back to the requirements language. No change made.</p>		
Madison Gas and Electric Co.	Ballot Comment	Please revise the words "System" to "system" or preface with BES System. NERC defines System to include distribution components. Plus this Standard is only applicable to PCs and TPs.

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
MidAmerican Energy Co.	Ballot Comment	Resolve the conflict between R2 and other requirements in the TPL standards by replacing the term, “System” with “BES” in various places throughout the standard when the reference should not be to the collective generation, transmission, and distribution systems, which is the definition of the NERC Glossary term, “System”. These locations are: R2.1.4, R2.1.5, R2.4.3, R2.6.2, R2.7, R2.7.1, R2.7.4, R2.8.1, R2.8.2, R3.5, R4.5, R5, and R6.
<p>Response: Even though the capitalized term “System” includes distribution components, the SDT believes that its usage within this standard is correct because the Reliability Standards apply only to the BES. Therefore, adding additional qualifiers is not needed. No change made.</p>		
City of Austin dba Austin Energy Lower Colorado River Authority	Ballot Comment	<p>Previous TPL Standard balloting included the FERC Order that clarified footnote ‘b’, regarding the planned or controlled interruption of electric supply for an N-1 situation. In our view, a Registered Entity’s Board of Directors, local public utility commission, and/or its customers should determine what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.</p> <p>Regarding R2 (2.5): The value of annually assessing system stability for years 6-10 is questionable. The requirement for stability assessment in years 6-10 should be limited to new generation interconnections or planned major transmission system improvements with regional impact. The standard should clarify the ‘material changes’ that would necessitate stability planning assessments and documentation.</p> <p>Regarding the R8 requirement to distribute all Planning Assessment results to adjacent Planning Coordinators and Transmission Planners is excessive and cumbersome. Regarding R8, we suggest the following language: Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners in accordance with the requirements of the applicable Reliability Coordinator. Any Registered Entity with a reliability-related need may submit a written request for the Planning Assessment results and the Transmission Planner or Planning Coordinator shall provide the latest Planning Assessment results within 30 days of such request.</p>
<p>Response: The SDT incorporated the language in Footnote 12 that was approved in Project 2010-11 TPL Table 1 Footnote B.</p> <p>For Requirement R2, Part 2.5, the SDT believes it is important to evaluate Stability when the planners are evaluating new generation additions or changes which can be more than 5 years in the future, as required in NERC Standard FAC-001-0. The SDT discussed defining ‘material change’ but did not believe that such a definition was appropriate in a continent-wide standard. With the wide variety in sizes and types of systems, the number of parameters that need to be considered, etc., there are too many variables involved. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
<p>For Requirement R8, the SDT disagrees that the requirement is excessive and cumbersome and did not make the suggested change. In addition, the proposed language would place requirements on the Reliability Coordinators, who are not included in the Applicability for this standard, and they should not be involved in determining the extent of the distribution of the Planning Assessments.</p>		
<p>City of Green Cove Springs City of Vero Beach Fort Pierce Utilities Authority Keys Energy Services</p>	<p>Ballot Comment</p>	<p>R7 is not needed and administrative in nature. Instead it should say that an entity can use as evidence another entity's study, but not in the requirement and rather in the measures.</p> <p>R8 is ambiguous, does the requirement require submitting the Planning Assessment only after receiving a written request, or automatic distribution to neighboring PCs and TPs without a written request, and to others with a reliability related need following a written request? <p>Response: Requirement R7 ensures that there are no gaps between Transmission Planners or the Planning Coordinators that may cause reliability concerns. No change made.</p> <p>Requirement R8 requires the automatic distribution to neighboring Planning Coordinators and Transmission Planners without a written request and to others with a reliability related need following a written request. The SDT believes this is an important consideration and not ambiguous. No change made.</p>		
<p>Alberta Electric System Operator</p>	<p>Ballot Comment</p>	<p>With respect to R2, Part 2.7.1 which lists system deficiencies and the associated actions needed to achieve System performance, the 3rd and 4th bullet identify the following actions as being acceptable: :Installation or modification of automatic generation tripping as a response to a single or multiple contingency to mitigate Stability performance violations. :Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations. The current Alberta transmission policy does not allow for the tripping or runback of generation for a single contingency; however for multiple contingencies it is acceptable.</p> <p>The AESO will bring TPL-001-2, with any modifications, through the standard development consultation process in Alberta and ultimately to the Alberta Utilities Commission for approval.</p>
<p>Response: The list in Requirement R2, Part 2.7.1 are examples of actions that are acceptable under the NERC Reliability Standard, however, certain actions may not be acceptable under state, provincial, or other regulatory policies or requirements and are not intended to supersede other regulations or policies.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
ReliabilityFirst	Yes	<p>1. In requirement 4.3, the high speed recloser time of 1 second is too restrictive. We suggest that the time be expanded to 2 seconds to capture all reclosing operations that might impact stability studies. We interpret the use of bullet points in Requirement 4.3.1 to mean that any one of the statements can be included in the analyses. In this requirement, the use of bullet points should be removed and replaced with language that requires all of the statements to be included in the analyses. We strongly believe that the language needs amended in requirement 4.3.1, such that, we will reconsider our voting position.</p> <p>2. In Table 1 labeled Steady State and Stability Performance Extreme Events we contend that the change to “relay failure” is unnecessarily limiting. The previous use of Protection system was satisfactory. Protection System is a defined term and encompasses many components that may fail and not just the relay.</p> <p>3. In table 1 Steady State & Stability Performance Planning Events under P5 “non-redundant” needs to be better defined. We suggest saying in a footnote that two devices do not need to be identical in order to be redundant. Redundant relays or relay schemes need to have the same performance level to be considered redundant but do not need to be identical equipment.</p>
<p>Response: The SDT believes that high speed reclosing is less than one second and has not received other comments that the time should be extended. The SDT believes that the language is clear that any of the three items shall be included in the analyses, if applicable. No change made.</p> <p>Table 1, Extreme Events, Stability Item 2 – The SDT made the language consistent with the language in the Planning Events to ensure that the planner was evaluating Stability based on performance of the System after the failure of a relay to operate and the planner should not address the many component failures that could create different failure modes. No change made.</p> <p>The SDT believes that non-redundant is understood by the industry. No change made.</p>		
Bonneville Power Administration	Yes	<p>1. If current study is performed to assess the system, there is no need to supplement with past studies. o Suggested language for R2.2:- For the planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed and be supported by the following annual current study or qualified past studies as indicated in Requirement R2, Part 2.6</p> <p>2. Load models should be consistent across the region o Suggested language for R2.4.1:- System peak load for one of the five years. System peak load levels shall include a the latest load model developed by the regional planning coordinator which represents the expected dynamic behavior of loads that could impact the study area, considering the behavior of induction motor loads.</p> <p>3. R2.5 is redundant and should be deleted. It is already included in R1.1.3 and R2.6.2.4. R3.5: This</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>standard requires mitigating the consequences of extreme events. Requiring potentially very costly mitigation actions for very low probability event is unnecessary burden to utilities.</p> <p>o Suggested language for R3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. Evaluation of the risk, consequences and adverse impacts of the event(s) shall be conducted.</p>
<p>Response: For Requirement R2, Part 2 - If the planner chooses to annually complete current studies to assess the system, the planner is not required to use past studies, but rather is allowed to use information from past studies in lieu of completing additional current studies. No change made.</p> <p>For Requirement R2, Part 2.4.1 – Not all Transmission Planners and Planning Coordinators are under a regional Planning Coordinator. However, for areas with a regional Planning Coordinator, that regional Planning Coordinator may have a requirement for all Transmission Planners and Planning Coordinators in its area utilize the regional Load model. No change made.</p> <p>Requirement R2, Part 2.5 is not redundant since the referenced requirements do not require the planner to assess the impact in the Long-Term Transmission Planning Horizon. The requirement is that the planners assess the impact of proposed material changes and have corrective action plans to resolve concerns from those proposed changes. The planner is not required to implement the corrective action plans unless the proposed material changes occur and the issues remain unresolved. No change made.</p> <p>Requirement R3, Part 3.5 – The SDT does not believe that the suggested language adds clarity and is also concerned that evaluation of possible actions to reduce the likelihood or mitigate the consequences and adverse impacts of the event are not required by the proposed language. No change made.</p>		
Ameren Services	Ballot Comment	<p>(1) Requirement R2.4.1, which addresses dynamic load modeling, has been a cause for concern because of the lack of guidance regarding reasonable induction motor representation as opposed to generic load models. While it is recognized that the effort to simulate the effects of induction motor loads is important, it is premature to include such modeling as part of the requirements for this standard.</p> <p>(2) For Measurements M3 and M4, there is still some question as to what is to be provided as sufficient evidence of a study. It is not clear whether the study results would be sufficient, or whether the entire powerflow, stability, or short circuit effort needs to be documented in a formal study report. For example, it is not clear whether contingency lists used in performing the study work would need to be retained as part of the documentation.</p> <p>(3) The standard as written is too prescriptive with regard to critical system conditions which are to be modeled. Such conditions would vary considerably for different systems across the continent. (4) Overall,</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		we believe that this standard does not improve the clarity of what is required, and would give additional occasions for disputes between compliance monitors and various registered entities.
<p>Response: For Requirement R2, Part 2.4.1, the SDT believes that there are models available that account for the dynamic nature of the Load. No change made.</p> <p>For Measurements M3 and M4, the planner is required to retain evidence that they completed the tasks required in each sub-part of Requirements R3 & R4. These sub-parts require evidence including steady state power flow, Stability and short circuit. Further, the Contingency lists are specifically required in Requirement R3, Parts 3.4 & 3.5 and Requirement R4, Parts 4.4 & 4.5. No change made.</p> <p>The SDT disagrees that the standard is too restrictive about the system conditions to be evaluated. The SDT believes that this standard is a significant improvement and adds needed clarity to the existing TPL standards. No change made.</p>		
New York State Reliability Council	Ballot Comment	<ol style="list-style-type: none"> 1. In R1.1.5, known commitments for Firm Transmission Service, plus other Interchange that does not violate reliability constraints - it is imperative to model other Interchange after accounting for all existing and planned Firm Transmission Service to ensure that reliability-based transactions are not confused with economic interchange. 2. In R2.2.5, the current requirement language can be interpreted to require evaluation of the simultaneous unavailability of multiple long-lead-time components. Also, as a transformer outage is already evaluated as part of category P6 in Table 1, additional studies should not be required; however, spare equipment strategies could be assessed in the context of the planning assessment. 3. In R2.2, the language in this requirement is materially inconsistent with R2.1, unnecessarily requiring a current study.
<p>Response: The SDT selected known commitments for Firm Transmission Service and Interchange to separate the planning requirements of commitments from the economic transactions. No change made.</p> <p>In Requirement R2, Part 2.1.5, the requirement is for the planner to make an assessment of the loss of long lead time (>1 year) equipment, unless the entity's spare equipment strategy can mitigate the issue in less than one year. Therefore, in those instances, the system will be evaluated against the system with the component out of service (multiple Contingencies). While P6 will simulate the same set of outages, the requirements of P1 and P2 are different than P6. Therefore, the planner needs to make an assessment of their system under the more stringent performance requirements. No change made.</p> <p>Requirement R2, Part 2.1 and 2.2 – The SDT left the requirement to conduct the annual study on one of the study years in the Long-Term Planning Horizon to ensure that the planner would conduct a new study annually to evaluate the System improvement needs in the Long-Term Planning Horizon. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
Tennessee Valley Authority	Ballot Comment	<p>1. TVA is concerned about the additional studies, modeling, and projects that must be performed to meet this proposed standard. TVA believes that this amount of work will have little overall improvement on the reliability of the BES.</p> <p>2. TVA believes that the 7 year implementation plan allowed for “Raising the bar” facilities does not allow sufficient time for TVA to construct the required new facilities. TVA average time for constructing a new 500-kV line can be up to 10 years, given the lead time on ROW and following all NEPA requirements. TVA does understand that the team has language (R2.7.3) regarding the TP or PC inability to get the projects completed through no fault of its own; however, there is no safeguard that the entity will be found non-compliant if all the work cannot be accomplished in this time frame.</p> <p>3. TVA believes that the footnotes b and c that allow for local load drop in the current TPL standards should still be allowed. TVA understands that this is addressed in FERC Order 693; however, the capital improvements to fix many of these issues will have little overall reliability gain for the Bulk Electric System. TVA believes that this is a local load reliability issue and not a BES concern.</p> <p>4. TVA is concerned that no generating unit shall pull out of synchronism for Planning Event P1, while the standard does allow generator runback/tripping for the same event. TVA believes that this requirement is overly burdensome without providing any material improvement in system reliability. Does distributed generation have to meet the same requirements for not pulling out of synchronism as a large nuclear unit?</p> <p>5. The Implementation Plan should include a five-year delay in the effective date for short circuit studies (R2 parts 2.3 and 2.8) since these studies are a new TPL requirement and are not required in the current version 0 standards.</p>
<p>Response: 1) The SDT appreciates the concern about additional work compared to the reliability benefits. The SDT believes that the changes within the proposed standard represent the appropriate work to ensure BES reliability. No change made.</p> <p>2) The SDT believes that the Implementation Plan gives entities the necessary time to develop and implement Corrective Action Plans. No change made.</p> <p>3) The SDT incorporated the language in Footnote 12 that was approved in Project 2010-11 TPL Table 1 Footnote B. No change made.</p> <p>4) The SDT does not believe that any generator should pull out of synchronism for a single Contingency. No change made.</p> <p>5) While short circuit study requirements may be new in the realm of mandatory enforceable standards, the SDT does not believe that they present a significant “raising of the bar” for industry. The SDT believes that prudent short circuit practices are effectively in place today to ensure safe operation of the equipment.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
<p>Therefore, no extension in the Implementation Plan was made in regard to short circuit studies.</p>		
<p>Florida Municipal Power Pool</p>	<p>Ballot Comment</p>	<p>A. Spare Equipment, R2.1.5 - The requirement reaches beyond the FERC directive. The directive was: "Accordingly, the Commission directs the ERO to modify the planning Reliability Standards to require the assessment of planned outages consistent with the entity's spare equipment strategy." So, the directive is only to address planned outage, not unplanned outages. Also note that the applicability to GSUs is ambiguous. "Transmission" is defined as: "An interconnected group of lines and associated equipment for the movement or transfer of electric energy between points of supply and points at which it is transformed for delivery to customers or is delivered to other electric systems." Is the "point of supply" the generator terminal, or the GSU high side terminal?</p> <p>B. Table 1, under first heading of "Steady State Only", bullet i is open to interpretation. Many utilities use steady state P-V analyses to study voltage stability and design UVLS systems in apart around those steady state analyses. Would this bullet essentially eliminate P-V and Q-V studies and the related use of UVLS?</p> <p>C. R7 is not needed and administrative in nature. Instead is should say that an entity can use as evidence another entity's study, but not in the requirement and rather in the measures.</p> <p>D. R8 is ambiguous, does the requirement require submitting the Planning Assessment only after receiving a written request, or automatic distribution to neighboring PCs and TPs without a written request, and to others with a reliability related need following a written request?</p> <p>E. Table 1, under first heading of "Steady State and Stability", bullet c should be removed since it is duplicative of the standard, and not entirely consistent with the standard (e.g., open to interpretation whereas the standard better clarifies how to study protection system operation)</p>
<p>Response: The SDT respectfully disagrees that the Commission directive regarding a spare equipment strategy is limited to planned outages. In Order 693, Par 1725, the Commission states in its discussion "Thus, if an entity's spare equipment strategy for the permanent loss of a transformer is to use a "hot spare" or to relocate a transformer from another location in a timely manner, the outage of the transformer need not be assessed under peak system conditions." The SDT believes FERC clearly intended the spare equipment strategy to cover a catastrophic loss of such long lead-time equipment. Further, the SDT believes it has appropriately limited this review to a small subset of the overall Planning Events – P0, P1, and P2 and for a loss that would be sustained for a year or longer. No change made.</p> <p>Table 1, Steady State and Stability, Item I does not restrict the use of UVLS since it only addresses equipment disconnected by end-user equipment. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>Requirement R7 ensures that there are no gaps between Transmission Planners or the Planning Coordinators that may cause reliability concerns. No change made.</p> <p>Requirement R8 requires the automatic distribution to neighboring Planning Coordinators and Transmission Planners without a written request and to others with a reliability related need following a written request. The SDT believes this is an important consideration and not ambiguous. No change made.</p> <p>Table 1, Bullet c under first heading, is not in conflict with the requirements. The SDT decided to include additional details in Table 1 so that it would have the basic information necessary for the planner to develop their simulations for their studies without always referring back to the requirements language. No change made.</p>
Modesto Irrigation District	Ballot Comment	<p>Both Sections 2.1.4 (seven sensitivities) and 2.4.3 (five sensitivities) require sensitivity studies to be run for all planning events and for all years specified , which increases the number of required studies beyond a reasonable and manageable limit.</p> <p>Also, both Section 2.1.4 and 2.4.3 specify that running studies over "...a range of credible conditions that demonstrate a measurable change in System response (performance)." must be completed, yet using "credible conditions" and also "demonstrating a measurable change in System response (performance)", may be mutually exclusive. "Measurable change in System response (performance)" is open to a broad interpretation, which increases the risk that the auditor may very likely interpret it differently than the utility system planner. The definition of the extreme events that have to be analyzed has been made nebulous, where in the existing standards they are quite specific.</p> <p>Requirement 2.1.5 requires the modeling of the loss of any system element that does not have a back-up or spare available sooner than 1 year, as part of the system normal state. It is not clear why using 1 year of loss of use for a system element is being used as the triggering point requiring further system enhancements. Thank you.</p>
		<p>Response: Requirement R2, Part 2.1.4 and Part 2.4.3 do not require an unreasonable amount of sensitivities, since they both state the planner must “vary one or more of the following conditions”. No change made.</p> <p>Requirement R2, Parts 2.1.4 and Part 2.4.3 allow the planner to use engineering judgment to determine the sensitivities to be completed. No change made.</p> <p>Requirement R2, Part 2.1.5 uses one year as a typical definition of a long lead time for equipment, so that the planner will assess their system performance without that equipment over peak periods. No change made.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
Hydro One Networks, Inc.	Ballot Comment	Hydro One Networks is casting a negative vote. Other than a few changes related to Footnotes 9 and 12 of Table 1 and VSLs, the other changes in the proposed draft are minor. The concerns of the industry on several important issues have not been sufficiently addressed in this draft. For detailed comments please refer to our submission through the on-line comment form.
<p>Response: The SDT posted a redline draft against the last posted draft and also posted a redline draft against the previous ballot draft. The SDT addressed important issues that were raised during the first ballot. Please see specific responses to your comments where they were submitted.</p>		
Luminant Energy	Ballot Comment	<p>Our most significant concerns are related to the following: (1) The requirements for Sensitivity Analysis are not stringent enough.</p> <p>(2) Studies should include variations in the duration and timing of transmission outages. "Anticipated" outages should be included in the studies and not just "known" transmission outages. It is our experience that only including "known" outages drastically under represents the actual number of transmission outages.</p> <p>(3) Major equipment outages lasting three or more months, as a result of Spare equipment strategies should be included in studies. The time limit of one year as specified in the Standard is too lax.</p> <p>Specific suggested language: 1.1.2. Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months or any known outage(s) of generation or Transmission Facility(ies) that will extend into the high stress period of the BES.</p> <p>2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies (as indicated in Requirement R2, Part 2.6, as follows). Qualifying studies shall include the following conditions:</p> <p>Add language between 2.1.3 and 2.1.4 to account for generation limitations due to Ancillary Services. Suggested wording: All planning studies must recognize and make provision for secure delivery of each of the Ancillary Services (eg Operating Reserve). In no case shall these studies double count capacity as being available for congestion management and Ancillary Services unless processes are in place to allow for location specific deployment of these Ancillary Service reserves for congestion management purposes.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>2.1.4 (bullet 7) Duration and timing of anticipated Transmission outages such as required maintenance activities.</p> <p>2.1.4 (bullet 8 added) Reasonable variations of anticipated generator availability after accounting for equivalent forced outage rate.</p> <p>2.1.5 If an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that would cause an outage of three months or more, (such as a transformer) the impact of this outage on System performance shall be studied.</p> <p>2.4.3. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:  Load level, Load forecast, or dynamic Load model assumptions.  Expected transfers.  Expected in service dates of new or modified Transmission Facilities.  Reactive resource capability.  Generation additions, retirements, or other dispatch scenarios.  Duration or timing of anticipated Transmission outages such as required maintenance activities.  Reasonable variations of anticipated generator availability after accounting for equivalent forced outage rate.</p> <p>2.4.4. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.</p> <p>2.4.5 If an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that would cause an outage of three months or more, (such as a transformer) the impact of this outage on System performance shall be studied.</p>
<p>Response: 1) The sensitivities addressed in Requirement R2, Parts 2.1.4 and Part 2.4.3 allow the planner to use engineering judgment to determine the sensitivities to be completed. Since sensitivities are included to ensure that the planner evaluates alternative conditions, it is necessary to allow flexibility to evaluate different types of changes that could occur. No change made.</p> <p>2) Reliability Standards are the minimum requirements and if conditions warrant, entities may add additional outages to be evaluated in their planning studies.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>No change made.</p> <p>3) Requirement R2, Part 2.1.5 uses one year as a typical definition of a long lead time for equipment, so that the planner will assess their system performance without that equipment over peak periods. No change made.</p> <p>For Requirement R2, Part 2.1, the SDT did not add language between Parts 2.1.3 and 2.1.4 to account for generation limitations due to Ancillary Services. The proposed addition assumes a particular market structure and that market structure is not uniform across North America. The “projected System conditions” in Requirement R1 would be violated if an entity double counted its Ancillary Services. No change made.</p> <p>Requirement R2, Part 2.1.4, bullet 7 & 8 are examples of sensitivities and the examples provided would address those contemplated by the SDT. No change made.</p> <p>Requirement R2, Part 2.1.5 uses one year as a typical definition of a long lead time for equipment, so that the planner will assess their system performance without that equipment over peak periods. No change made.</p> <p>Requirement R2, Part 2.4.3 – Since the five conditions for sensitivities have been vetted through six postings, the SDT did not add the two proposed conditions. No change made.</p> <p>Requirement R2, proposed 2.4.4 – Since the known outages are already included in the cases, as required by Requirement R.1, Part 1.1.2, there is not a need to require specific studies that include them – No change made.</p> <p>Requirement R2, proposed Part 2.4.5 – The proposed requirement is already contained in Requirement 2, Part 2.1.5 and does not need to be duplicated here. The SDT has used the typical one year time period to define long lead time for equipment and believes that three months is too short a time period for this requirement. No change made.</p>
MidAmerican Energy Co.	Ballot Comment	<p>Regarding Requirement 8, there is not a significant risk to the reliability of the BES if an annual Planning Assessment is not distributed to another entity or if a documented response to Planning Assessment comments is not provided within 90 days of a request. Requirement 8 is an administrative requirement that adds little to improve reliability.</p> <p>We recommend that the VRF for Requirement 8 remain “Low”, rather than be changed to “Medium”.</p>
<p>Response: The SDT believes that sharing the Planning Assessments with adjacent Transmission Planners and Planning Coordinators is an important component of the planning process.</p> <p>The SDT did not change the VRF. The previous change reflects the latest guidelines on the topic.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
Consolidated Edison Co. of New York	Ballot Comment	Requirement R1.1.5: Delete “and Interchange.” The inclusion of other than Firm transactions (e.g. economic transactions in Interchange) in a base power flow case utilized for planning/designing the interconnected system blurs the boundary between reliability issues and purely economic issues. Reliability issues are issues that a Transmission Owner (TO) must address for the purpose of meeting its load demand, and are defined by the application of well established reliability standards and criteria that are based on the electrical characteristics of the interconnected system, but without economic considerations. Instead, economic transactions are types of transactions that a TO may enter into once its load obligations are met, and are evaluated based on economic parameters that are markedly different from the aforementioned reliability criteria (e.g. congestion costs). Modeling all types of transactions in a power flow case without distinction detracts from the accuracy and validity of either assessment (reliability and economic).
<p>Response: Requirement R1, Part 1.5 does not require Interchange for economic purposes. The requirement is to represent “Known commitments”. No change made.</p>		
Platte River Power Authority	Ballot Comment	Stability requirements R4.1.2, along with the second and third bullets of R4.3.1, could be misunderstood to require the development of comprehensive relaying models for all Facilities represented in the stability model. These requirements should be made clear that Stability studies are to simulate the effects of relaying (tripping certain Facilities) and not require relaying models to trigger and cause the effects.
<p>Response: The SDT language in Requirement R4, Part 4.3.1 states “The analyses shall include the impact of subsequent” and does not require comprehensive relaying models. However, it does require that the planner take into account the effects of System Protection on System performance. No change made.</p>		
GDS Associates, Inc.	No	<p>1. Footnotea. Footnote should state “Draft 7” instead</p> <p>2. Requirement R1a. Time Horizon should include both Near-term and Long-term Planning3. Requirement R2a. Time Horizon should include both Near-term and Long-term Planningb.</p> <p>Requirement R2, Part 2.1</p> <ul style="list-style-type: none"> o The inclusion of the words "For the Planning Assessment" it seem unnecessary as long as main requirement R2 is only about the Planning Assessment and nothing else. o The term “Qualifying studies” from the last sentence is referring to the qualified past studies, or the annual studies, or both actually? Suggesting adjusting the verbiage so it would not create confusion. o Subpart 2.1.4- Requirement R2, Part 2.1.1 and Part 2.1.2 are referring to system conditions, not studies. The second sentence may be subject of non-objective interpretations and may generate burdensome and

Organization	Yes / No	Question 1 Comment
		<p>unrealistic amount of work. The requirement should state instead "For each of the system conditions described in Requirement R2, Part 2.1.1 and Part 2.1.2, the studies shall include sensitivity cases utilized to demonstrate whether there is any significant impact due to changes on the basic assumptions used in the model. The analysis, by case, may contemplate varying one or more of the following conditions:"</p> <ul style="list-style-type: none"> o Subpart 2.1.5- We suggest adjusting the time threshold of potential equipment unavailability in order to be consistent with the time frame for the "known Transmission outages". c. Requirement R2, Part 2.2 o The inclusion of the words "For the Planning Assessment" it seem unnecessary as long as main requirement R2 is only about the Planning Assessment and nothing else. o While the Near-Term portion of the Planning Assessment details the premises of the study, the Long-Term is lacking in such thing. d. Requirement R2, Part 2.3 o Although both the steady-state and transient stability studies are required for the Near-Term and Long-Term, the short-circuit study is required only for the Near-Term. This is big disconnect, because there can be stability analyses conducted without a short-circuit assessment. o Breakers should be checked for their breaking capability, as well as to withstand the fault. All other disconnecting equipment, as well as current transformers in particular shall be also verified for their withstand capabilities. The current statement should be replaced with "The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term and Long-Term Transmission Planning Horizon and can be supported by current or past studies as indicated in Requirement R2, part 2.6. The analysis shall be used to assess performances of transmission elements affected by a potential increase of short-circuit contributions to fault" e. Requirement R2, Part 2.4 o The inclusion of the words "For the Planning Assessment" it seem unnecessary as long as main requirement R2 is only about the Planning Assessment and nothing else. o Similar with 2.1, the last sentence should read "The studies should include the following conditions:" o Subpart 2.4.1- We believe that the dynamic behavior of the load cannot be accurately estimated beyond current time. We are concerned about the effort required to ascertain the dynamic response of the load. As for the "Loads that could impact the study area" the standard doesn't include any directions in how an entity will identify these loads. Perhaps the standard should provide guidelines to determine which loads would impact the study area. o Subpart 2.4.3- See comments from Subpart 2.1.4f.

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>Requirement R2, Part 2.5 o The inclusion of the words "For the Planning Assessment" it seem unnecessary as long as main requirement R2 is only about the Planning Assessment and nothing else.</p> <p>g. Requirement R2, Part 2.6 o Subpart 2.6.2- We agree with the suggested changes as responding to previous commentsh.</p> <p>Requirement R2, Part 2.7 o Subpart 2.7.1- We disagree with the implemented changes. The standard should not include examples. If needed, a white paper can accompany the standard. We suggest adjusting the last sentence to read "Such actions may include, but are not limited to, the following:"</p> <p>i. Requirement R2, Part 2.8 o This should apply to all disconnecting equipment and CT in particular with respect not only to their interrupting duty, but to their withstand capabilities also. See comment on Part 2.3.4. Table 1a. Footnote 9</p> <p>o With respect to the Curtailment of Firm Transmission Service we suggest SDT to revise the language in order to be consistent with the Implementation Plan.</p> <p>5. Measure M1a. This measure it is hard to read. For simplicity, we suggest adjusting this measure to read "Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format that it is maintaining System models within their respective area, using data consistent with MOD-010 and MOD-012, and the models reflect the System conditions in accordance with Requirement R1."</p> <p>6. Measure M7a. The measure encompasses the particular scenario where the parties involved have reached an agreement for performing the required studies. In order to cover situations where the parties have not reach an agreement, the measure should read "Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies all individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7."</p> <p>7. Compliancea. Data retention o The 5th bullet should read "The documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response since the last compliance audit in accordance with Requirement R5 and Measure M5."</p> <p>o The 6th bullet should read "The documentation specifying the criteria or methodology used to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding since the last compliance audit in accordance with Requirement R6 and Measure M6."</p> <p>o The 7th bullet should be reworded in accordance with suggested changes at M7.</p>

Organization	Yes / No	Question 1 Comment
		<p>Response: 1. This is the sixth time that this standard has been posted for comments. The reference to a seventh posting on the web site is because the standard was posted once for informational purposes. No change made.</p> <p>2. Requirement R1. Per the standards process, the Time Horizon for this standard is Long-term Planning; which includes both the Short-Term and Long-Term Planning Horizon. No change made.</p> <p>3. Requirement R2, Part 2.1 – “For the Planning Assessment” were added in a previous draft for clarity – No change made.</p> <p>Requirement R2, Part 2.1 – “Qualifying Studies” could be either or both – No change made.</p> <p>Requirement R2, Part 2.1.4 – The requirement is for the planner to have a completed study for each of the conditions in Parts 2.1.1 & 2.1.2. The requirement to complete sensitivity studies has been included to ensure that the planner tests their system by stressing the system beyond what is within their base cases. Since the System conditions vary across North America, the relevant sensitivities are best determined by the planner. The proposed language does not convey the same intent. No change made.</p> <p>Requirement R2, Part 2.1.5 – The SDT determined that the impact of “known outages ...” does not directly correlate to the entity’s spare equipment strategy. No change made.</p> <p>c. Requirement R2, Part 2.2 – “For the Planning Assessment” were added in a previous draft for clarity – No change made.</p> <p>Requirement R2, Part 2.2 - The SDT limited the requirements in the Long-Term to allow the planner more latitude in that time frame, while ensuring that the planner conducted a Long-Term assessment of their portion of the BES. No change made.</p> <p>d. Requirement R2, Part 2.3 - A planner may choose to complete a short circuit study in conjunction with its Long-Term Steady State and Stability studies, but the SDT does not believe that the planner should be required to complete a short circuit study in the Long-Term Transmission Planning Horizon. No change made.</p> <p>The SDT agrees that any system element must be able to withstand the stresses that they may be subjected to, however, the standard must ensure BES reliability. Therefore, the SDT limited the requirement to the breakers since they protect other system elements from the fault. No change made.</p> <p>e. Requirement R2, Part 2.4 – “For the Planning Assessment” were added in a previous draft for clarity . The SDT does not believe that replacing the last sentence as proposed adds any additional clarity. No change made.</p> <p>Requirement R2, Part 2.4.1 – The SDT believes that the planner must consider the dynamic behavior of its System Load and develop a representative model, however, the SDT should not dictate “how” the Load should be modeled. Those specific details must be included in the model by the individual planner. No change made.</p> <p>Requirement R2, Part 2.4.3 - The requirement is for the planner to have a completed study for each of the conditions in Parts 2.4.1 & 2.4.2. The requirement to</p>

Organization	Yes / No	Question 1 Comment
		<p>complete sensitivity studies has been included to ensure that the planner tests their system by stressing the system beyond what is within their base cases. Since the System conditions vary across North America, the relevant sensitivities are best determined by the planner. The proposed language does not convey the same intent. No change made.</p> <p>Requirement R2, Part 2.5 – “For the Planning Assessment” were added in a previous draft for clarity – No change made.</p> <p>Requirement R2, Part 2.7.1 – The SDT has included limited examples where we believe that additional clarity is needed. Since the list is clearly marked as “examples”, the SDT believes the phrase “but not limited to”, is not required. No change made.</p> <p>Requirement R2, Part 2.8 - The SDT agrees that any system element must be able to withstand the stresses that they may be subjected to, however, the standard must ensure BES reliability. Therefore, the SDT limited the requirement to the breakers since they protect other system elements from the fault. No change made.</p> <p>The Implementation Plan has been revised as suggested although the SDT wishes to point out that no dates have been changed.</p> <p>Measure M1 – While the suggested language is shorter it does not contain all of the terminology of the matching requirement and thus violates a basic guideline for measures. No change made.</p> <p>6. Measure 7 – The suggested language doesn’t change the assumed scenario cited and provides no additional clarity. No change made.</p> <p>7. Data retention, 5th bullet – The SDT agrees that for consistency the suggested terms should be added so that this bullet matches up with the language of the requirement.</p> <p>DR, 5th bullet: The documentation specifying the criteria <u>for acceptable System steady state voltage limits, post-Contingency voltage deviations, and transient voltage response</u> since the last compliance audit in accordance with Requirement R5 and Measure M5.</p> <p>Data retention, 6th bullet - The SDT agrees that for consistency the suggested terms should be added so that this bullet matches up with the language of the requirement.</p> <p>DR, 6th bullet: The documentation specifying the criteria or methodology utilized <u>in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding</u> in support of its Planning Assessments since the last compliance audit in accordance with Requirement R6 and Measure M6.</p> <p>Data retention, 7th bullet – The SDT declined to make the suggested changes to Requirement R7 so no change is necessary for Measure M7.</p>
<p>United Illuminating ISO New England Inc</p>	<p>No</p>	<p>a. 2.6.2 - What was the intent of this change? The old language seemed to work. The language should not be changed from the previous version.</p> <p>b. For 2.8.2 - Was the phrase changed to reflect modifications of facilities? If so the requirement should be</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>modified to read “Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures with respect to modifications of facilities. Otherwise the requirement is unclear.</p> <p>c. For Section R8.1 - the proposed requirement conflicts with a long standing stakeholder process in our area which posts study results and allows comment within a defined period before studies are finalized. If this section is to be retained then it should be modified to only allow comments on Transmission studies less than one-year old. Requirement 8 and 8.1, should be revised to include a limit on the comment period as follows: If a recipient of the planning assessment final results provides documented comments on the results within 90 days of receipt, the respective Planning Coordinator or Transmission Planner shall provide a documented response to such recipient within 90 calendar days of receipt of those comments.</p> <p>d. With respect to Table 1 - We suggest adding an event 6 to P1 to address the contingent loss of back to back HVDC Facilities. If not added to P1 then this event needs to be added somewhere in the standard.</p> <p>e. We don’t agree with footnote 7 specifying that only one end of the line should be open for this condition. If the SDT is to keep this concept make P2 event 1 simply say “Opening one end of a line section w/o a fault” and delete the footnote. The existing footnote is unclear due to the use of language such as “possibly”.</p>
<p>Response: a. Requirement R2, Part 2.6.2 was revised in response to comments that a “qualified” study may have material changes remote from the area of study and the previous version would not have allowed the use of that study. No change made.</p> <p>b. Requirement R2, Part 2.8.2 – The added phrase – “of identified System Facilities and Operating Procedures” was added to ensure that it was clear what “implementation status” was referencing. No change made.</p> <p>c. Requirement R8, Part 8.1 - The SDT does not believe that the requirement conflicts with other stakeholder processes and does not believe that a time limit is required. Beyond responding to the comment, other actions by the planner are at the discretion of the planner. No change made.</p> <p>d. Table 1, P1 back to back DC - The contingent loss of back to back HVDC facilities is included as a transformer. Footnote 5 states, in part, that “Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. Therefore, the SDT has not explicitly included back-to-back HVDC as a separate Contingency. No change made.</p> <p>e. Table 1, footnote 7 – The SDT added the footnote to further explain its intent for P2-1 and to ensure that the planner assess the voltage of a load bus that was on a radial line. The word “possibly” was used since having load on a radial is not always the outcome of opening one end of a line section. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
Northeast Utilities	No	<p>Definition of Terms Used in the Standard The definitions of “Near-Term Transmission Planning Horizon” and “Year One” have been deleted from the standard, yet they are still used in draft 7. NU is concerned about voting in favor of this standard with these terms being defined by another project without a full discussion of the impact to this proposed standard. NU suggests repeating the definitions in this proposed standard.</p> <p>Requirement R1 NU believes that the Normal System Conditions as stated in Requirement R1 should establish the base case conditions to be used for the assessment studies. However, a more detailed guideline for developing base cases should be addressed by the requirements. By just modifying the language of requirement R1 to indicate that “P0” constitutes the initial system conditions does not address this concern in Draft #7.</p> <p>A more detailed guideline for base case development is needed.</p> <p>Requirement R8 The wording in requirement R8 needs to be amended to restrict comments to the most recent assessment only, for a limited period (say 3 months) after its release. The current wording appears to offer unlimited opportunity to comment on past assessments, long after their release.</p> <p>Footnote 7 It appears there is a discrepancy between Footnote 7 and Event P2-1. Footnote 7 could be eliminated by rewording Event P2-1 as follows: “Opening one end of a line section w/o a fault”.</p> <p>Footnote 12 NU did not agree with the clarification of Table 1 Footnote B of TPL-002 and did not vote for its approval. Therefore, NU does not agree with the same clarification being applied here for Non-Consequential Load Loss. For reference, below is NU’s comment on TPL-002 Table 1, Footnote B:”The revised language of Footnote b suggests that non-consequential demand interruption (load that is not directly served by the elements removed from service as a result of the contingency) could be used to mitigate reliability concerns arising from NERC Category B contingency events (i.e., single element contingencies). This language seems to encourage operational workarounds and adds burdens for operators of the system. NU believes this is not consistent with planning a highly reliable bulk electric system and thus does not support this weaker language”.</p> <p>General comment NU believes that a standard should contain statements and requirements that are direct and measurable. TPL-001-2 should not be an exception to this rule. Therefore, statements like “An objective” which appears in Footnotes 9 and 12 shall not be used.</p>
<p>Response: Definitions of Near-Term Transmission Planning Horizon and Year One are now approved NERC Glossary Terms and are no longer needed in this proposed standard. The definitions have been vetted through this process through the 1st six postings of this standard and were approved by the Commission in</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>FAC-013.</p> <p>With the wide variety of system conditions and market structures across North America, the SDT chose not to establish a single set of conditions for a base case. Each planner shall establish their base case that meets their needs and their other regulatory requirements. No change made.</p> <p>Requirement R8, Part 8.1 - The SDT does not believe that a time limit for commenting on a Planning Assessment is required. Beyond responding to the comment, other actions by the planner are at the discretion of the planner. No change made.</p> <p>Table 1, P2-1 – The SDT does not agree that there is a discrepancy between the Contingency and Footnote 7. Footnote 7 was utilized to clarify a specific condition that would need to be evaluated as a part of P2-1. No change made.</p> <p>Footnotes 12 and 9 were translated from the BOT approved language from TPL-002-1, Footnote 'b'.</p>
<p>Electric Reliability Council of Texas, Inc.</p>	<p>No</p>	<p>ERCOT ISO believes that the revisions do not go far enough in addressing previously submitted comments. As written this standard would require restructuring of the functions in the ERCOT Region because several requirements are being assigned to the PC that are currently performed only by the TPs. It would not provide any reliability benefits to have the ERCOT PC assume these functions.</p> <p>Specifically, the following requirements should be modified: R2.1.5 should be clarified to be applicable to TPs only since the ERCOT PC does not have the information necessary to perform this analysis;</p> <p>R2.3 and R2.8 should be clarified to be applicable to TPs only since the ERCOT PC does not perform this analysis (it is performed by the TPs in ERCOT);</p> <p>R4.1.2 should be clarified to only apply to TPs because the ERCOT PC does not have the modeling information necessary to perform this analysis.</p> <p>Additionally, R2.1.4 and R2.4.3 should be removed because the requirements are subjective and there are no actions prescribed to be taken based on the sensitivity results. The Load model requirement should be removed from R2.4.1 because this would be better addressed in a MOD standard.</p> <p>Alternatively, R2.4.1 should be rewritten as “System peak Load for one of the five years with expected dynamic load models.” A concurrent requirement should be incorporated to mandate DSPs and TPs to supply dynamic load model data to the PC to perform the required studies.</p>
<p>Response: Requirement R2, Part 2.1.5 requires that studies be completed based on an entity's spare equipment strategy. The ERCOT Planning Coordinator could utilize Requirement R7 to document the individual and joint responsibilities for these studies and document the outcome of these studies. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>Requirement R2, Parts 2.3 and 2.8 – The ERCOT Planning Coordinator could utilize Requirement R7 to document the individual and joint responsibilities for these studies and document the outcome of these studies. No change made.</p> <p>Requirement R4, Part 4.1.2 requires the Transmission Planner and Planning Coordinator to accurately represent the behavior of the system if a generator pulls out of synchronism. Therefore, this information is needed by each Transmission Planner and Planning Coordinator to ensure that the appropriate system response is modeled. No change made.</p> <p>Requirement R2, Parts 2.1.4 and R2.4.3 require the completion of sensitivity studies and allows the planner the discretion on which variables to vary. In addition, Requirement R2, Part 2.7 requires Corrective Action Plans to address issues that are present in multiple sensitivities. The MOD standards only require data to be submitted, and this requirement allows the variation of the forecasted load as one of the possible sensitivities. No change made.</p> <p>Requirement R2, Part 2.4.1 – The SDT believes that the drafted language more clearly explains the requirement than the proposed language. This requirement is for the planner to utilize models that reflect the dynamic nature of the load with an expectation that the planner will obtain the required information in Requirement R1 to determine how it is modeled. No change made.</p>
Independent Electricity System Operator	No	<p>IESO is generally supportive of the draft of TPL-001-2 as evidenced by our previous AFFIRMATIVE vote during the last ballot. Further, IESO also supported the revisions to Footnote ‘b’ to Table 1 of the TPL standards under Project 2010-11. That revision was balloted and approved by the ballot pool in February 2011 and filed with FERC for approval in March 2011. The revised footnote has been incorporated into the current draft of TPL-001-2 as Footnotes 9 and 12 but the Commission, by letter to NERC dated May 17, 2011, has requested NERC to provide supplemental information before the revised Footnote ‘b’ could be approved. In light of FERC’s request and the uncertainty regarding the final provisions of these footnotes, coupled with the ongoing work on Project 2010-17 for the revision of the BES definition and development of an Exception Process and the impact that may have, we respectfully suggest that the drafting team delay further work on TPL-001-2 pending FERC’s ruling on NERC’s petition seeking approval of the transmission planning standards that contain the revised Footnote ‘b’ to Table 1.</p>
<p>Response: The SDT believes that it is important to continue with the approval of this standard. If FERC directs changes based on TPL-002-1, Footnote ‘b’, they will be addressed with this project.</p>		
New York Independent System Operator	No	<p>If the following recommended revisions are made to the requirements listed, subject to other unforeseen material changes, NYISO would no longer oppose the approval of this standard.</p> <p>Requirement R2.1.5 The current requirement language can be interpreted to require evaluation of the simultaneous unavailability of multiple long-lead-time components. Also, as a transformer outage is already</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>evaluated as part of category P6 in Table 1, additional studies should not be required, however spare equipment strategies could be ASSESSED in the context of the Planning Assessment.</p> <p>NYISO thus recommends this requirement be revised as follows: R 2.1.5 When an entity’s spare equipment strategy could result in the unavailability of a major Transmission component that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed with due regard to categories P0, P1, and P2 identified in Table 1.</p> <p>Requirement R2.2The language in this requirement is materially inconsistent with R2.1, unnecessarily requiring a current study. NYISO requests that R2.2 and the sub-requirement be revised as follows:2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies shall include: 2.2.1. Expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.</p> <p>Requirement R8.1There is an apparent open ended time frame afforded report recipients in their review of any Planning Assessment. This requirement should apply to only the most recent Planning Assessment. NYISO thus recommends the following language: 8.1. If a recipient of the most recent Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.</p>
<p>Response: Requirement R2, Part 2.1.5 is not the same as P6 – Table 1, however, the analysis for P6 could be utilized, if the results show there will not be load loss. Except for the outages being evaluated under P0, P1, and P2 for individual components out of service without a long term spare, the requirement does not require the evaluation of the simultaneous loss of multiple long lead time components. The SDT believes that the language “with due regard to” is not as clear as the proposed language. No change made.</p> <p>Requirement R2, Part 2.1 and 2.2 – The SDT left the requirement to conduct the annual study on one of the study years in the Long-Term Planning Horizon to ensure that the planner would conduct a new study annually to evaluate the System improvement needs in the Long-Term Planning Horizon. No change made.</p> <p>Requirement R8, Part 8.1 - The SDT does not believe that a time limit for commenting on a Planning Assessment is required. Beyond responding to the comment, other actions by the planner are at the discretion of the planner. No change made.</p>		
NBSO	No	Items that, if not addressed, will likely cause a negative vote from NBSO:R2.2 differs from R2.1, R2.3, R2.4 and R2.5 since R2.2 does not state that the annual assessment of the Long-Term Transmission Planning

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>Horizon portion of the steady state analysis can be supported by qualified past studies. Likely this omission is an oversight, but unresolved it can cause significant burden with little gain in reliability.</p> <p>Individual items that, if not addressed, may not cause NBSO to vote Negative, but in combination may result in a negative vote: The language of requirements R2.1.4 and R2.4.3 allowing the performance of one or more sensitivities appears to be inconsistent with language in R2.7.2 that requires multiple sensitivities to determine if actions to resolve performance deficiencies are necessary.</p> <p>R7 (and M7) seem to indicate that the PC is ultimately responsible for determining the individual and joint responsibilities for performing the required planning assessment studies, with the expectation to consult and come to agreement with its corresponding TPs, but this interpretation is not clear. The correct interpretation of this requirement is important for resolving situations where a PC and TP do not agree on the assignment of responsibilities. Suggested wording: “Each PC shall work in conjunction with each of its TPs to determine and identify...”</p> <p>The language in R8 is unclear. One point of confusion relates to which entity is responsible for sending their Planning assessments to other entities. For example, who does a PC distribute their planning assessments to?: -Adjacent PC? (Seems to be clearly addressed)-TPs within its PC footprint? (Not clearly covered by the language in R8)-TPs adjacent to its PC footprint (Not clear if this is the responsibility of the PC, TP or both) In addition, the language in R8.1 appears to offer unlimited opportunity to request response to comments on any past assessment, long after their release. Providing limits in the language of R8.1 is recommended in order to avoid unnecessary burden on PCs and TPs for little gain in reliability or constructive stakeholder involvement.</p>
<p>Response: Requirement R2, Part 2.1 and 2.2 – The SDT left the requirement to conduct the annual study on one of the study years in the Long-Term Planning Horizon to ensure that the planner would conduct a new study annually to evaluate the System improvement needs in the Long-Term Planning Horizon. No change made.</p> <p>Requirement R2, Parts 2.1.4 and 2.4.3 are not inconsistent with Requirement R2, Part 2.7.2. With the various requirements, the planners are required to conduct multiple sensitivities. Therefore, Requirement R2, Part 2.7.2 could be used when the results of these multiple sensitivities identify common concerns. No change made.</p> <p>Requirement R7 – The SDT believes that the current language addresses the various arrangements that could exist between the Planning Coordinator and Transmission Planner, better than the proposed language. If agreement is not reached, both the Planning Coordinator and the Transmission Planner would be required individually to perform all of the required studies. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
<p>Requirement R8 – Each planner is required to distribute its Planning Assessment to all adjacent planners (Transmission Planners and Planning Coordinators). Requirement R8, Part 8.1 - The SDT does not believe that a time limit for commenting on a Planning Assessment is required. Beyond responding to the comment, other actions by the planner are at the discretion of the planner. No change made.</p>		
Hydro One Networks Inc.	No	Other than a few changes related to Footnotes 9 and 12 of Table 1 and VSLs, the other changes in the April 15, 2011, draft are minor. The concerns of the industry on several important issues have not been sufficiently addressed in this draft (see our response to Question 3).
<p>Response: Please see the response to Question 3.</p>		
Manitoba Hydro	No	-R2.1.4 and R2.4.3: 'Expected transfers' should be replaced with 'Firm Transmission Service and Interchange' to correlate to R1 (R1.1.5 states 'Known commitments for Firm Transmission Service and Interchange' must be represented in system mode
<p>Response: Requirement R2, Parts 2.1.4 and R2, Part 2.4.3 use the more inclusive term - Expected transfers – for sensitivities. The SDT does not want to unnecessarily restrict the transfers that could be evaluated as a part of a sensitivity study. No change made.</p>		
Associated Electric Cooperative Inc	No	<p>R2.4.1:The SDT has put a stronger emphasis on dynamic load behavior in stability studies (FIDVR, induction motor loads, etc) to be included in the peak models. The standard does indicate that “An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.” We feel that this should be clarified to ensure that the current modeling processes address what NERC desires with this requirement. At a minimum, we recommend that a grace period be implemented to account for any regional modeling practices which need time to implement dynamic load behavior per the draft standard.</p> <p>R2.5:It is our understanding that the Long-Term Transmission Planning Horizon does not require the sensitivity analysis which is required in R2.4 for the Near-Term Transmission Planning Horizon for the stability portion of the studies.</p> <p>R2.7:It is our understanding that Corrective Action Plan(s) do not need to be developed for performance violations observed in the sensitivity analysis (steady state and stability) unless the violation is observed in several sensitivities as it is indicated in R2.7.2: “Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide rationale for why actions were not necessary”. We feel</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>that this needs to be further clarified.</p> <p>R3.3.1:This requirement indicates that steady state analysis should include the effect of ride-through voltage limitations of generating units. We are having difficulty seeing how this is a steady-state issue. Generally one would expect a generator to experience ride-through voltage issues during faults. Per Table 1, P1.1 already require generator outages be taken - wouldn't that cover this issue? We feel that this needs to be further clarified.</p> <p>R3.4.1:This requirement states that "Transmission Planners shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list". We feel that the coordination requirement should be removed from the standard as this will result in a massive increase in workload/time required to perform the TPL studies. AECI has several ties to adjacent Transmission Planners and Planning Coordinators - it will be a very time intensive task to coordinate with all of these parties. If the standard wants to ensure that the Contingencies overlap - we can agree to that, however we feel that the SDT needs to give some firm clarity on how far to go with it (how many buses away, only include ties, etc?).</p> <p>R4.1.2:We would like clarification on what is mean by "apparent impedance swings".</p> <p>R4.3.1:Is the intent of the SDT to require that generic or actual relay models be added to the stability models? We feel that this needs to be further clarified.</p> <p>R8:This requirement states that the Planning Assessments shall be distributed within 90 days of their completion to adjacent Planning Coordinators, Transmission Planners, and functional entities that have a reliability need (3rd Interconnection Customers?). We do not agree with the mandatory requirement of distributing the results of our TPL studies: We consider this information to be CEII We can agree to distribute the results upon request, but do not agree with the 30 day timeframe as more time will be needed to sign applicable Non-Disclosure Agreements, etc.</p>
<p>Response: Requirement R2, Part 2.4.1 – The SDT has allowed flexibility for the planner to determine how to meet this requirement. The implementation plan has allowed at least 24 months for coordination and development of modeling practices. No change made.</p> <p>Requirement R2, Part 2.5 – Sensitivities are not required for years in the Long-Term Transmission Planning Horizon.</p> <p>Requirement R2, Part 2.7 – Your understanding of the need for Corrective Action Plans to address deficiencies identified by sensitivity studies is correct. The SDT believes that the proposed language is clear. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>Requirement R3, Part 3.3.1 – Within the steady state analysis, the planner is required to represent the actual state of each generator based on the system response to a contingency and this includes voltage ride-through for generators. Table 1, P1-1 does not address this issue, since it is only a single generator outage and the requirements of Requirement R3, Part 3.3.1 could be a generator out of service (because it doesn't ride-through) as a result of a more severe contingency. No change made.</p> <p>Requirement R3, Part 3.4.1 – The SDT added the requirement to coordinate Contingency lists to ensure that these lists do not omit Contingencies on adjacent systems that may cause performance concerns. The SDT believes that most planners are already considering outages on the fringes of their neighbors system to ensure that they meet the performance requirements. The SDT does not agree that this will be a massive increase in workload for planners. No change made.</p> <p>Requirement R4, Part 4.1.2 – The “apparent impedance swing” is the trajectory of changes in the apparent impedance seen by a distance relay for various system and fault conditions. In the case contemplated in Requirement R4, Part 4.1.2, it is the trajectory seen by the distance relay for the initial fault and the subsequent generator(s) pulling out of synchronism. If that trajectory were to come within the tripping characteristic of the relay for a sufficient length of time, the relay would cause its associated line to trip. No change made.</p> <p>Requirement R4, Part 4.3.1, bullet 3 – The planner may reflect the effects of either generic or actual relay models. No change made.</p> <p>Requirement R8 – The SDT believes that 30 days should be adequate time to get the necessary agreements in place to make the Planning Assessment available. No change made.</p>
National Grid	No	<p>R2.8.2We recommend this requirement be clarified with the following modification: The Corrective Action Plan shall:2.8.1. List System deficiencies and the associated actions needed to achieve required System performance. 2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of planned modifications to System Facilities and Operating Procedures.</p>
<p>Response: The proposed change of “identified” to “planned modifications to” does not change the proposed requirement or add clarity. No change made.</p>		
Consolidated Edison Co. of NY, Inc.	No	<p>Requirement R1.1.5: Delete “and Interchange.” The inclusion of other than Firm transactions (e.g. economic transactions in Interchange) in a base power flow case utilized for planning/designing the interconnected system blurs the boundary between reliability issues and purely economic issues. Reliability issues are issues that a Transmission Owner (TO) must address for the purpose of meeting its load demand, and are defined by the application of well established reliability standards and criteria that are based on the electrical characteristics of the interconnected system, but without economic considerations. Instead, economic transactions are types of transactions that a TO may enter into once its load obligations are met, and are evaluated based on economic parameters that are markedly different from the aforementioned reliability criteria (e.g. congestion costs). Modeling all types of transactions in a power flow</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		case without distinction detracts from the accuracy and validity of either assessment (reliability and economic).
<p>Response: Requirement R1, Part 1.5 does not require Interchange for economic purposes. The requirement is to represent “Known commitments”. No change made.</p>		
Nebraska Public Power District	No	<p>The existing TPL-001 through TPL-004 Standards and Requirements are clear and concise. The new merged TPL-001-1 Standard and Requirements is no longer clear and concise.</p> <p>Further, the modification made to allow an SPS to trip a remote generator for an N-1 (TPL-002) type of event is a degradation of system reliability. Transmission system facilities should be added to maintain stability for a new generator interconnection for any N-1 Category B event. An SPS should not be relied upon for a Category B event, an SPS should only be allowed for Category C & D (TPL-003 & TPL-004) type events.</p>
<p>Response: The SDT believes that there is much less ambiguity in the proposed standard than the existing standards.</p> <p>There is no restriction in the existing TPL-002-1 on a planner’s ability to utilize an SPS to trip a remote generator for a Category B event and the SDT did not change this. No change made.</p>		
Northeast Power Coordinating Council	No	<p>The wording of Part 1.1.2, “known outages...with a duration of at least 6 months” should be revised to “...at least 1 year”. Also for consideration is that “known outages...with a duration of at least 6 months” are dealt with in operational studies rather than planning studies. Any adverse impacts that these outages might have are mitigated by operational decisions rather than planning decisions within a 6 month horizon. Moving this requirement out of the TPL Standard to an operational standard should be considered.</p> <p>Make the wording consistent between 2.1 and 2.2 as it relates to qualified past studies. Specifically:Parts 2.1.2, 2.1.4, 2.1.5The language of requirements 2.1.4 and 2.4.3 allowing the performance of one or moresensitivities appears to be inconsistent with language in 2.7.2. 2.7.2 requires multiplesensitivities to determine if actions to resolve performance deficiencies are necessary.Will varying only one measurable quantity several times in multiple simulationssatisfy multiple sensitivity studies or just one sensitivity study? The numbers and types of required sensitivity studies is unclear, and subject to interpretation by PCs and TPs.</p> <p>The current wording in Part 2.1.5, “spare strategy”, appears to be open-ended regarding the number of</p>

Organization	Yes / No	Question 1 Comment
		<p>permutations to be analyzed. It should be restricted to assessing only one piece of equipment being unavailable or outaged at a time.</p> <p>2.1.5 should be consistent with R2 and 2.1 regarding the use of the terms assessment and studies. As with the preceding comment regarding Part 1.1.2, moving this requirement out of the TPL Standard and to an operational standard should be considered. It is unclear if the last sentence of R2.1.5 allows for the curtailment of firm transmission service before the application of category P0, P1 and P2 events. This last sentence states: "...with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment."</p> <p>The wording in Part 2.2 "be supported by the following annual current study, supplemented with qualified past studies" should be replaced with the similar statement in Part 2.1: "be supported by current annual studies or qualified past studies".</p> <p>Part 2.7.1 lists potential system actions to address System deficiencies. It is suggested that this list be moved to a guideline or white paper.</p> <p>The wording in Part 8.1 needs to be amended to restrict comments to the most recent assessment only. Contingencies on back to back HVDC installations are not mentioned in the standard. The treatment of combined cycle facilities (all units in outage?) needs to be clarified, as well as Footnote 7 of Table 1 requiring clarification.</p> <p>In Table 1, Event 1 of Category P2 and related Footnote 7 are not clear because of the use of the word "possibly". If the intension is to simulate the line end opening condition of tapped lines, this should be clearly stated in the table (without reference to "Opening of a line section" and use of different language in the footnote).</p> <p>From Table 1b: "Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0." Firm Transmission Services Loss is also acceptable and should be added (particularly in P1 loss of a single pole of a DC line for which the transfer is reduced accordingly to the remaining pole capability).</p>
<p>Response: Requirement R1, Part 1.1.2 does not address the outages in the operational time frame. However, if a planner knows that a System component is going to be out of service for more than 6 months, the planner must model the component outage in the appropriate models and evaluate the System to ensure that the System meets the performance requirements of the standard. No change made.</p> <p>Requirement R2, Part 2.1 and 2.2 – The SDT left the requirement to conduct the annual study on one of the study years in the Long-Term Planning Horizon to</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>ensure that the planner would conduct a new study annually to evaluate the System improvement needs in the Long-Term Planning Horizon. No change made.</p> <p>Requirement R2, Part 2.1.4 and 2.4.3 each require two studies on sensitivity cases, but more studies can be performed by the planner. Requirement R2, Part 2.7.2 states that Corrective Action Plans are required (or rationale for why they are not needed) are required if performance deficiency exists in multiple sensitivity studies, not just one study. No change made.</p> <p>Requirement R2, Part 2.1.5 requires the study of each major Transmission equipment outage, consistent with spare equipment strategy, for System normal and P1 and P2 Contingencies. It does not require the study of P1 and P2 Contingencies with more than one major Transmission equipment, except for other equipment that are modeled out as “Known outages” consistent with Requirement R1, Part 1.1.2. No change made.</p> <p>Requirement R2, Part 2.1.5 is a planning requirement to ensure that an entity's spare equipment strategy is considered during the development of the Planning Assessment. The curtailment of Firm Transmission Service (FTS) for the situation outlined would be considered curtailing FTS for Normal System conditions and is not allowed. No change made.</p> <p>Requirement R2, Part 2.1 and 2.2 – The SDT left the requirement to conduct the annual study on one of the study years in the Long-Term Planning Horizon to ensure that the planner would conduct a new study annually to evaluate the System improvement needs in the Long-Term Planning Horizon. No change made.</p> <p>Requirement R2, Part 2.7.1 – The list represents examples, but not an exhaustive list of actions that could make up a Corrective Action Plan. No change made.</p> <p>Requirement R8, Part 8.1 - The SDT does not believe that a time limit for commenting on a Planning Assessment is required. Beyond responding to the comment, other actions by the planner are at the discretion of the planner. No change made.</p> <p>Table 1, P1 {back to back DC - The contingent loss of back to back HVDC facilities is included as a transformer. Footnote 5 states, in part, that “Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. Therefore, the SDT has not explicitly included back-to-back HVDC as a separate Contingency. No change made.</p> <p>Combined cycle generation outages are expected to be modeled in the manner that they would be tripped, per Requirement R3, Part 3.3.1 and Requirement R4, Part 4.3.1. Therefore, if the outage of one generator causes more generation to be lost (via the Protection System or other automatic controls are expected to disconnect), then, the entire amount of generation lost must be modeled for that specific contingency. No change made.</p> <p>Table 1, footnote 7 – The SDT added the footnote to further explain its intent for P2-1 and to ensure that the planner assess the voltage of a load bus that was on a radial line. The word “possibly” was used since having load on a radial is not always the outcome of opening one end of a line section. No change made.</p> <p>Table 1, Top note 1b – The SDT disagrees that Firm Transmission Service (FTS) may be interrupted for all events. The events where the interruption of FTS is not permitted are shown with a “No” in the column titled “Interruption of Firm Transmission Service Allowed”, however, footnote 9 clarifies that interruption of Firm Transmission Service can be used as both a corrective action and system adjustment as permitted within Table 1. For the specific issue raised, loss of a single pole of a DC line, to the extent the availability of the DC pole is a condition of the transfer being viable, footnote 4 may also address the commenter's</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
concern. No change made.		
Ameren	No	<p>There were a number of comments made on the previous draft of TPL-001-2 for which there were few, if any, changes made to the latest draft of the standard. Specifically: Requirement R1 does not address normal (pre-contingency) operating procedures or system configurations. Language should be added to the requirement (possibly as an additional Requirement R1.1.7) to include normal operating procedures or system configurations in place prior to any contingency occurring.</p> <p>Requirement R2.4.1, which addresses dynamic load modeling, has been a cause for concern because of the lack of guidance regarding reasonable induction motor representation as opposed to generic load models. While it is recognized that the effort to simulate the effects of induction motor loads is important, it is premature to include such modeling as part of the requirements for this standard. In addition, it appears that only the peak load model in R2.4.1 is required to represent expected dynamic behavior of Load. Such load models, if adopted should represent dynamic behavior of the load for all dynamic studies.</p>
<p>Response: The SDT posted a redline draft against the last posted draft and also posted a redline draft against the previous ballot draft. The SDT addressed many important issues that were raised during the first ballot.</p> <p>The SDT did not include all of the different procedures that are permitted. Normal operation procedures or system configuration may be utilized as long as they are consistent with the way the System would be operated and not inconsistent with the requirements within the standard.</p> <p>Requirement 2, Part 2.4.1 – One focus of dynamic Load model requirement in Part 2.4.1 is “considering the behavior of induction motor Load”. The areas of concern for induction motor Load are the Peak Load periods since Fault Induced Delayed Voltage Recovery (FIDVR) is primarily a concern at high Load levels with a high penetration of induction motor Loads. The SDT has spelled out this requirement in the Peak Load studies but did not include the explicit requirement, with focus on induction motor Load, for the other Load periods. Even though the standard doesn’t have the explicit requirement for other Load levels, Requirement R1 includes the statement “shall represent projected System conditions”, so the planner cannot ignore the dynamic behavior of the Load for those other Load periods. No change made.</p>		
Western Area Power Administration	No	<p>We concur that the standard is an improvement over previous drafts, but we vote "No" to the existing draft and request additional clarifications and/or modified language for a re-circulated vote prior to adoption. The following are areas where we suggest improvement or have questions: Please further define Consequential and/or Non-Consequential Load Loss: Does the Consequential Load Loss definition include underfrequency or undervoltage load shedding installed to protect transmission system reliability?</p> <p>Does the Consequential Load Loss definition include load tripped by a Special Protection System (SPS) or a</p>

Organization	Yes / No	Question 1 Comment
		<p>Remedial Action Scheme (RAS)?</p> <p>Either how underfrequency and undervoltage load shedding or how load shedding by a RAS relates to Consequential Load Loss should be clear in the Consequential and/or Non-Consequential Load Loss definition of the approved version of this NERC standard.</p> <p>Why is Near-Term Transmission Planning Horizon deleted from the definitions of Terms Used in this Standard, yet it is used throughout the standard? This definition should remain.</p> <p>R1.1.5: How are “known commitments for Firm Transmission Service” to be modeled and tracked in power flow cases? Is it acceptable for Transmission Planners to simply assume what the ultimate sources and ultimate sinks are for each firm transmission service commitment or are Transmission Planners to know exactly which ultimate sources and ultimate sinks are associated with each commitment and to track each one accordingly in each power flow case? Assuming the intent here is reliability based and not marketing based, is the application of Firm Transmission intended to apply to reliability designated ‘paths’? Most all Firm Transmission service contracts have caveats for unplanned interruption and such agreements should qualify as “re-dispatch” per Footnote 9?</p> <p>R2.1.5: If a group of utilities were to develop and manage among themselves a coordinated spare equipment program, such that the risk to any one of its participating entities of experiencing a significant unavailability for any major Transmission equipment that has a lead time of one year or more is deemed not significant, then would those utilities still have to do the studies required by R2.1.5 to evaluate the system impact of extended outages of such equipment? Scenario for Clarification: Short of spare equipment for items with a greater than 1 yr lead time, assessment studies are required to include sensitivities and operating plans for sustained loss of these equipment items, as a prior outage. For example, if an EHV facility is lost for more than 1 yr, and firm transmission interruption is not allowed, it appears the only compliant alternative (to a redundant facility) is a redispatch plan that is well documented and accepted by all stakeholders, per Footnote 9.</p> <p>R2.3: Is only the 5-year Near-Term Transmission Planning Horizon case required for the annual short-circuit analysis?</p> <p>R2.4.1: How is the dynamic modeling of induction motor Loads to be developed by the Transmission Planners? Is it acceptable for Transmission Planners to assume the same induction motor modeling as has generally been assumed and applied by most Transmission Planners throughout the Western Interconnection or will the induction motor modeling have to be based upon the type and amount of actual</p>

Organization	Yes / No	Question 1 Comment
		<p>induction motors installed in the system?</p> <p>R2.5: Does NERC have a particular technical rationale about what determines “proposed material generation additions or changes?”</p> <p>R2.6.2: Does NERC have a particular technical rationale about what determines “material changes?”</p> <p>R2.7.3: Please define “beyond the control” under Definition of Terms Used in Standard. This is an important concept. Without NERC definition, this term is highly debatable and should be eliminated. Scenario for Clarification: If the stakeholder rate payers do not approve expenditures for facility improvements required to eliminate non-consequential load loss, is this beyond the control of the Transmission Planner? Rate payers should be able make the ultimate free market choice determination of risk versus cost associated with their reliability. Otherwise market interests (particularly generation) disproportionately pressure excessive reliability based improvements that must be borne by all rate payers.</p> <p>R3.3.1: Please define “relay loadability limit” under Definitions of Terms Used in Standard. This is an extremely important concept. This term has been used quite commonly for decades and is now used in this latest proposed standard. Without NERC definition, this term is highly debatable and should be eliminated. Scenario for Clarification: If PRC-023 is met whereby all “relay loadability limits” are set at least 150% of the highest thermal limiter (0.85 voltage and 30 lagging powerfactor) this sensitivity would justifiably not be needed so long as verification is shown that no element overloaded greater than 150%.</p> <p>R3.1 and R3.4: The interrelation between these two paragraphs needs additional clarification. R3.1 calls for verification via studies that the BES meets Table 1 performance criteria based on the contingency list resulting from R3.4. However, R3.4 states that the contingency list used to meet R3.1 only need include “Those planning events in Table 1, that are expected to produce more severe System impacts on.....the BES” and the associated “rationale” for those chosen contingencies. Is NERC suggesting that the studies do not need to include all contingencies based on Table 1, so long as ample “rationale” is provided? However, the Transmission Planner must provide studies to determine if every contingency of Table 1 meets performance requirements. How are the “more severe” contingencies determined if the Table 1 contingencies are not evaluated comprehensively? It seems R3.4 could be eliminated and the contingencies be based simply on Table 1. Please define “more severe”, relative to less severe under Definitions of Terms Used in Standard, in an effort to help evaluate the suitability of a particular contingency for inclusion on this list. Looking at context, it appears that the purpose of this statement is to ensure that the worst contingencies are studied. Is the intent here simply to allow a given contingency to cover for a less severe or similar contingency and avoid duplicate simulations?</p>

Organization	Yes / No	Question 1 Comment
		<p>R3.4.1 and R4.4.1 Please include and define a reasonable number of contingent buses into adjacent systems that should be considered. No more than 2 are recommended for the standard.</p> <p>R3.5 and R4.5: How many of the “events in Table 1 that are expected to produce more severe system impacts” should the required evaluation identify and evaluate?</p> <p>To what extent should the evaluation focus on the “other” Extreme Events described under items 3.b and 2.f in Table 1, particularly if existing disturbance reports in the Western (or Eastern) Interconnection have recorded and evaluated the occurrence of particular events that have already created cascading? Because the requirement seems to involve a check for Cascading, perhaps some clarity could be provided with respect to the NERC definition of “Cascading.” In particular, in the Cascading definition, how widespread is “widespread;” is the phrase “electric service interruption” only about the loss of firm load or could it also be only about the loss of firm generation or only about the loss of firm transmission service or is it about some combination of loss of firm load, loss of firm generation, and loss of firm transmission service; how large an area is meant by the expression “spreading beyond an area predetermined by studies” when the simulations that analyze the initiating Extreme Event will model the entire Western (or Eastern) Interconnection? So how does the study determine that the sequentially spreading service interruption has spread beyond the entire Western (or Eastern) Interconnection that is modeled in the simulation? Or is the term “area” meant to describe only that part of the Western (or Eastern) Interconnection that the Transmission Planner has evaluated for system impacts while ignoring impacts to the rest of the Interconnection?</p> <p>Table 1 - Planning Events, Steady State Only Note i: “The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event” seems to be included as items 2) and 3) under the Non-Consequential Load Loss definition. So, it seems acceptable to use this form of load loss to meet the stability performance requirements. However, the “Steady State Only” note i in Table 1 specifically does not allow its use to meet steady state performance requirements. Therefore, the “Steady State Only” note i in Table 1 should clarify why it seems acceptable to use it to meet stability performance requirements but not to meet steady state performance requirements.</p> <p>Table 1 - Planning Events, Category P2: Category P2 seems to include an unrelated mix of planning events ranging from a seemingly benign event (i.e., opening of a line section without a fault) to what would seem to be much more severe events (i.e., bus section fault or internal breaker fault). A clarification of why these planning events were lumped into the same Category P2 would be helpful to the Transmission Planner. Also, does the language in footnote 7 (i.e., “opening one end of a line section without a fault on a normally networked Transmission circuit ...”) mean that P2-1 (“opening of a line section without a fault”) should be</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>modeled as an open-ended line section?</p> <p>Table 1 - Planning Events, P2-2 (EHV) and P2-3 (EHV): For each of these planning events, its corresponding “Non-Consequential Load Loss Allowed” column should include a footnote 12 with each of the “No” boxes, similar to that allowed under the seemingly much less severe event P2-1 (“opening of a line section without a fault”). Otherwise, please explain why the seemingly much less severe P2 event (P2-1) has a footnote 12 exception for Non-Consequential Load Loss Allowed but the two seemingly more severe P2 events (P2-2 and P2-3) do not.</p> <p>Table 1 - Planning Events, P4-1 through P4-5 (EHV): For the stuck breaker planning events of P4-1 through P4-5 on the EHV system, their corresponding “Non-Consequential Load Loss Allowed” column should include a footnote 12 with their “No” box, similar to that allowed under the seemingly much less severe N 1 planning events (P1-1 through P1-5). Otherwise, please explain why the seemingly much less severe N 1 events (P1-1 through P1-5) have a footnote 12 exception for Non-Consequential Load Loss Allowed but the seemingly much more severe stuck breaker events (P4-1 through P4-5) do not.</p> <p>Table 1 - Planning Events, P5-1 through P5-5 (EHV): For the relay failure planning events of P5-1 through P5-5 on the EHV system, their corresponding “Non-Consequential Load Loss Allowed” column should include a footnote 12 with their “No” box, similar to that allowed under the seemingly much less severe N 1 events (P1-1 through P1-5). Otherwise, please explain why the seemingly much less severe N 1 events (P1-1 through P1-5) have a footnote 12 exception for Non-Consequential Load Loss Allowed but the seemingly much more severe relay failure events (P5-1 through P5-5) do not.</p>
<p>Response: The definition of Consequential Load Loss does not include underfrequency or undervoltage load shedding, since this Load is not interrupted by the “Protection System operation designed to isolate the fault”. No change made.</p> <p>The definition of Consequential Load Loss does not include Load tripped by a Special Protection System (SPS) or a Remedial Action Scheme (RAS), since this Load is not interrupted by the “Protection System operation designed to isolate the fault”. No change made.</p> <p>The definition of Near-Term Transmission Planning Horizon is now an approved NERC Glossary Term. No change made.</p> <p>Requirement R1, Part 1.1.5 (Known commitments for Firm Transmission Service and Interchange) is required to ensure that planners consider those transactions that have been committed to and meet the system performance requirements. “How” the planners account for these commitments should be developed by the planner in accordance to all of the regulatory and market rules that apply to them. No change made.</p> <p>Requirement R2, Part 2.1.5 does not require a planner to study the unavailability of major long lead time equipment if the entity’s spare equipment strategy could</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 1 Comment
		<p>not result in the unavailability of that equipment for one year or more. No change made.</p> <p>Requirement R2, Part 2.3 requires the short circuit analysis only for the years of the Near-Term Transmission Planning Horizon. No change made.</p> <p>Requirement R2, Part 2.4.1 – The SDT believes that the planner must consider the dynamic behavior of its System load and develop a representative model, however, the SDT should not dictate “how” the load should be modeled. No change made.</p> <p>Requirement R2, Part 2.5 does not specify “how” an entity determines that “proposed material generation additions or changes” have occurred. It is up to each entity to develop its technical rationale for its determination. No change made.</p> <p>Requirement R2, Part 2.6.2 does not specify “how” an entity determines that “material changes” have occurred. It is up to each entity to develop its technical rationale for its determination. No change made.</p> <p>Requirement R2, Part 2.7.3 has been included to account that certain Corrective Action Plans may not be able to be implemented due to circumstances that the planner cannot control. The SDT expects that these situations will be limited and that the impact to BES will be limited to interrupting Non-Consequential Load if the Contingency were to occur. Due to the wide variety of circumstances across North America, the SDT did not believe that it was appropriate to articulate the acceptable set of conditions. No change made.</p> <p>Requirement R3, Part 3.3.1 utilizes the term “relay loadability limits” as it is utilized in the PRC standard. No change made.</p> <p>Requirement R3, Parts 3.1 and 3.4 together require the planner to create a list of the “more severe” Contingencies, along with the rationale for “why” those Contingencies were selected, that will be simulated to ensure that the System meets the performance requirements. This language was included to be consistent with the existing TPL standards that do not require the planner to run simulations of all possible Contingencies. No change made.</p> <p>Requirements R3, Part 3.4.1 and Requirement R4 Part 4.4.1 do not include “how” to define the Contingencies in adjacent systems that should be included since it will be variable based on the conditions of the System. It is the responsibility of the planners to coordinate the list of Contingencies to ensure BES reliability. No change made.</p> <p>Requirement R3, Part 3.5 and Requirement R4 Part 4.5 require the planner to identify the “events in Table 1 that are expected to produce more severe system impacts”. The number of “events” that should be included in the list are a “how” that the planner must determine. No change made.</p> <p>Table 1, Extreme Events Steady State 3b and Stability 2f are included to ensure that the planner considers “operating experience” when determining the extent of Contingency analysis to conduct for the entity’s Extreme Event simulations. The term “widespread” categorizes those events that are more far-reaching than the Local Area events identified in Extreme Events Steady State 2 a-e. No change made.</p> <p>Table 1, Top note ‘i’ Steady State Only does not apply to Stability studies. Therefore, voltage sensitive Load disconnected by end-user equipment may be used during Stability simulations. The planner should not depend on this voltage sensitive Load being disconnected to meet the performance requirements (steady state after the system transient reaction ends) but this Load should be disconnected from the System for the Stability simulations to accurately represent how the</p>

Organization	Yes / No	Question 1 Comment
		<p>System will respond. No change made.</p> <p>Table 1, P2 contains single Contingency events that have the same performance requirements. No change made.</p> <p>Table 1, P2-1 covers the opening of line section without a fault and Footnote 7 clarifies that the line section may be energized from one end and still serving Load. The expectation is that both situations are evaluated when appropriate. No change made.</p> <p>Table 1 P2-2 (EHV) and P2-3 (EHV) do not allow the exception allowed by Footnote 12. The SDT believes that the EHV system should be planned to handle these single Contingencies without Non-Consequential Load Loss. No change made.</p> <p>Table 1, P4-1 through P4-5 (EHV) does not allow the exception allowed by Footnote 12. The SDT believes that the EHV system should be planned to handle these Contingencies without Non-Consequential Load Loss. No change made.</p> <p>Table 1, P5-1 through P5-5 (EHV) does not allow the exception allowed by Footnote 12. The SDT believes that the EHV system should be planned to handle these Contingencies without Non-Consequential Load Loss. No change made.</p>
Progress Energy		<p>First, Progress Energy ("PE") notes that many changes to the Requirements language have been appropriate or have improved upon the language of the previous drafts, and PE commends the SDT in this. PE does have concerns, however, with the language in R8 and its corresponding Measure M8, and therefore must select 'no' for Q1 and provide comments. PE disagrees with the language of R8 primarily to the extent that the use of the verb "distribute" with respect to communicating Planning Assessments leads the reader to M8, which lacks language that would provide for the optimal correlation with R8. Regarding the M8 language, PE feels that the term "demonstration of a public posting" is a valid action in demonstrating compliance with R8 and thus should be more clearly described as one of several acceptable methods of distributing Planning Assessments. In addition, given the appropriate concern that NERC and FERC have recently raised regarding Cyber threats and the need for additional Cyber Security measures, PE feels that the public posting language should contain a qualification regarding the security of CEII information. PE thus recommends that an appropriate phrase to use would be "demonstration of a secure public posting", thereby making clear that a public posting would not be a website accessible to just anyone due to CEII concerns.</p>
<p>Response: Requirement R8 - The SDT agrees that posting is an acceptable method of distributing but the intent of the standard requirement is to ensure that affected parties obtain the Planning Assessment. Measure M8 clarifies that posting is acceptable but not the only way to meet the requirement. While the SDT recognizes that certain planning information is covered by CEII requirements, the responsibility to protect that information already resides with the entity and is therefore not needed within this standard. No change made.</p>

2. The SDT has made revisions to the VRF and VSL of TPL-001-2 which will be part of a non-binding poll with this posting based on industry comments and the Quality Review. Do you agree with these changes? If you do not support these changes or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Summary Consideration: Comments received were predominantly about individual assessments of whether a VRF or VSL had been assigned correctly and some pointed out what they thought were incorrect interpretations of established guidelines by the SDT. The SDT followed guidelines established by FERC and NERC in these areas and therefore no changes were made in this regard.

In two particular instances, inconsistencies between wording in the requirement and VSL were pointed out and the SDT made the following changes due to those comments:

R1. VSL – Severe (third part): The responsible entity's System model did not use ~~the latest~~ data consistent with ~~the data that~~ provided in accordance with the MOD-010 and MOD-012 standards and other sources, including items represented in the Corrective Action Plan.

<p>R8 VSL</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 90 days but less than or equal to 120 days following its completion.</p> <p>OR,</p> <p>The responsible entity distributed its Planning Assessment <u>results</u> to functional entities having a reliability related need who requested the Planning Assessment in writing but</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 120 days but less than or equal to 130 days following its completion.</p> <p>OR,</p> <p>The responsible entity distributed its Planning Assessment <u>results</u> to functional entities having a reliability related need who requested the Planning Assessment in writing but</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 130 days but less than or equal to 140 days following its completion.</p> <p>OR,</p> <p>The responsible entity distributed its Planning Assessment <u>results</u> to functional entities having a reliability related need who requested the Planning Assessment in writing but</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 140 days following its completion.</p> <p>OR</p> <p>The responsible entity did not distribute its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners.</p>

--	--	---	---	---

Organization	Yes / No	Question 2 Comment
Consolidated Edison Co. of New York	Ballot Comment	Requirement R1.1.5: Delete “and Interchange.” The inclusion of other than Firm transactions (e.g. economic transactions in Interchange) in a base power flow case utilized for planning/designing the interconnected system blurs the boundary between reliability issues and purely economic issues. Reliability issues are issues that a Transmission Owner (TO) must address for the purpose of meeting its load demand, and are defined by the application of well established reliability standards and criteria that are based on the electrical characteristics of the interconnected system, but without economic considerations. Instead, economic transactions are types of transactions that a TO may enter into once its load obligations are met, and are

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
		evaluated based on economic parameters that are markedly different from the aforementioned reliability criteria (e.g. congestion costs). Modeling all types of transactions in a power flow case without distinction detracts from the accuracy and validity of either assessment (reliability and economic).
<p>Response: The SDT selected Known commitments for Firm Transmission Service and Interchange to separate the planning requirements of commitments from the economic transactions. No change made.</p>		
San Diego Gas & Electric	Ballot Comment	The clarity of this standard is getting worse. Our earlier comments did not seem impacting. At this point, we believe the existing TPL-001-0.1, TPL-002-0a, TPL-003-0a and TPL-004-0 provide much better clarify for us to comply with the TPL standards.
<p>Response: The SDT believes that there is much less ambiguity in the proposed standard than the existing standards, based on feedback from previous postings. . No change made.</p>		
Alberta Electric System Operator	Ballot Comment	The AESO casts an abstain vote as the VSLs and VRFs in Alberta are established by provincial authorities.
<p>Response: Thank you for your response.</p>		
Western Electricity Coordinating Council	Ballot Comment	I'm not certain that I agree with changing the VRF for R2 from Medium to High. I understand that it is accordance with the VRF guidelines, but I guess I disagree with the guidelines. I don't believe that any requirement with a planning time frame, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.
<p>Response: The SDT is required to follow the VRF guidelines established by FERC, which apply to both operations and planning on equal footing. No change made.</p>		
Florida Municipal Power Agency	Ballot Comment	FMPA has minor comments to help improve the clarity of the standard. R7 is not needed and administrative in nature. Instead is should say that an entity can use as evidence another entity's study, but not in the requirement and rather in the measures.

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
		<p>R8 is ambiguous, does the requirement require submitting the Planning Assessment only after receiving a written request, or automatic distribution to neighboring PCs and TPs without a written request, and to others with a reliability related need following a written request?</p> <p>Table 1, under first heading of "Steady State and Stability", bullet c should be removed since it is duplicative of the standard, and not entirely consistent with the standard (e.g., open to interpretation whereas the standard better clarifies how to study protection system operation)</p>
<p>Keys Energy Services City of Green Cove Springs</p>	<p>Ballot Comment</p>	<p>R7 is not needed and administrative in nature. Instead is should say that an entity can use as evidence another entity's study, but not in the requirement and rather in the measures.</p> <p>R8 is ambiguous, does the requirement require submitting the Planning Assessment only after receiving a written request, or automatic distribution to neighboring PCs and TPs without a written request, and to others with a reliability related need following a written request?</p> <p>Table 1, under first heading of "Steady State and Stability", bullet c should be removed since it is duplicative of the standard, and not entirely consistent with the standard (e.g., open to interpretation whereas the standard better clarifies how to study protection system operation)</p>
<p>Response: Requirement R7 ensures that there are no gaps between Transmission Planners or the Planning Coordinators that may cause reliability concerns. No change made.</p> <p>Requirement R8 requires the automatic distribution to neighboring Planning Coordinators and Transmission Planners without a written request and to others with a reliability related need following a written request. The SDT believes this is an important consideration and not ambiguous. No change made.</p> <p>Table 1, Bullet c under first heading, is not in conflict with the requirements. The SDT decided to include additional details in Table 1 so that it would have the basic information necessary for the planner to develop their simulations for their studies without always referring back to the requirements language. No change made.</p>		
<p>City of Austin dba Austin Energy</p>	<p>Ballot Comment</p>	<p>Previous TPL Standard balloting included the FERC Order that clarified footnote "b" regarding the planned or controlled interruption of electric supply for an N-1 event. In our view, a Registered Entity's Board of Directors, local public utility commission or customers should determine the acceptable level of service and the associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.</p> <p>Additionally, with respect to R2 (2.5), the value of annually assessing system stability for years 6-10 is</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
		<p>questionable. The requirement for stability assessment in years 6-10 should be limited to new generation interconnections or planned major transmission system improvements with regional impact. The standard should clarify the "material changes" that would necessitate stability planning assessments and documentation.</p> <p>Finally, The R8 requirement to distribute all Planning Assessment results to adjacent Planning Coordinators and Transmission Planners is excessive and cumbersome. Regarding R8, we suggest the following language: "Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and Transmission Planners in accordance with the requirements of the applicable Reliability Coordinator. Any Registered Entity with a reliability-related need may submit a written request for the Planning Assessment results and the Transmission Planner or Planning Coordinator shall provide the latest Planning Assessment results within 30 days of such request."</p>
<p>Response: Footnotes 12 and 9 were translated from the BOT approved language from TPL-002-1, Footnote 'b'. No change made.</p> <p>For Requirement R2, Part 2.5, the SDT believes it is important to evaluate Stability when the planners are evaluating new generation additions or changes which can be more than 5 years in the future, as required in NERC Standard FAC-001-0. The SDT discussed defining 'material change' but did not believe that such a definition was appropriate in a continent-wide standard. With the wide variety in sizes and types of systems, the number of parameters that need to be considered, etc., there are too many variables involved. No change made.</p> <p>For Requirement R8, the SDT disagrees that the requirement is excessive and cumbersome and did not make the suggested change. In addition, the proposed language would place requirements on the Reliability Coordinators, who are not included in the Applicability for this standard, and they should not be involved in determining the extent of the distribution of the Planning Assessments.</p>		
Southwest Power Pool Regional Entity	Ballot Comment	I'm voting affirmative, but I'd prefer to avoid having VSLs where the only choice is Severe. I'd like to see either some gradation or we should use a different term to clarify that the requirement is either met or not (binary) instead of Severe VSL.
<p>Response: The SDT is required to follow the guidelines established by NERC and FERC. No change made. No change made.</p>		
Arizona Public Service Co.	Ballot Comment	While AZPS generally supports this standard, AZPS cannot support the violation severity levels that are proposed in the recirculation ballot. AZPS believes the time frames set forth in the proposed security levels are unreasonably short (10 days) and should be extended to 30 days between each elevation in severity level. For these reasons, AZPS has changed its vote to "negative."

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
<p>Response: The SDT has followed the accepted guidelines for timeframes in the proposed VSLs. The SDT is required to follow the guidelines established by NERC and FERC. . No change made.</p>		
Balancing Authority of Northern California NCR11118	Ballot Comment	SMUD believes believes that the VRF should be Medium, as are the VRFs for the other requirements related to conducting the assessments, rather than High.
<p>Response: The SDT is required to follow the VRF guidelines established by FERC,.. No change made.</p>		
Black Hills Corp	Ballot Comment	Black Hills is voting against the proposed VRF/VSL's based on the fact that the VRF for R2 was changed from Medium to High without any explanation.
Deseret Power	Ballot Comment	R2 was moved from medium to high without reason. Since it is long term it should remain medium.
California ISO	Ballot Comment	The VRF for Requirement R2 was changed from Medium to High without explanation. The other VRF's for assessment requirements continue to have a Medium VRF designation, and for consistency it would be appropriate for Requirement R2 to continue to have a Medium VRF designation.
Bonneville Power Administration	No	The VRF for R2 was changed from Medium to High without any explanation. Since the time horizon for R2 is Long Term Planning, BPA believes that the VRF should be Medium, as are the VRFs for the other requirements related to conducting the assessments, rather than High.
Arizona Public Service Company	No	With regards to R2, it appears that the VRF has changed from Medium to High without any justification; and with the time horizon of long term planning, AZPS believes there is no justification for changing it from Medium to High.
Idaho Power Company	Ballot Comment	The VRF for R2 was changed from Medium to High without any explanation. The time horizon for R2 is Long Term Planning and the Idaho Power believes that the VRF should be Medium, as are the VRFs for the other requirements related to conducting the assessments, rather than High.
Tucson Electric Power Co.	Ballot	This recommendation is based on the fact that the VRF for R2 was changed from Medium to High without any

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
	Comment	<p>explanation.</p> <p>The time horizon for R2 is Long Term Planning and it is believed that the VRF should be Medium, as are the VRFs for the other requirements related to conducting the assessments, rather than High.</p>
<p>Response: In the comment form for this posting, the SDT did address this issue as shown below:</p> <p>R2 – The VRF has been changed to High to reflect the importance of the Planning Assessment and to meet the latest guidelines. No change made.</p>		
MidAmerican Energy Co.	Ballot Comment	<p>Regarding Requirement 8, we do not believe that there is significant risk to the reliability of the BES if an annual Planning Assessment is not distributed to another entity or if a documented response to Planning Assessment comments is not provided within 90 days of a request. Requirement 8 is an administrative requirement that adds little to improve reliability. We recommend that the VRF for Requirement 8 remain “Low”, rather than be changed to “Medium”.</p>
<p>Response: In assigning the VRF for Requirement R8, the SDT is required to follow the guidelines established by NERC and FERC. No change made.</p>		
Independent Electricity System Operator	Ballot Comment	<p>IESO is generally supportive of the draft of TPL-001-2 as evidenced by our previous AFFIRMATIVE vote during the last ballot. Further, IESO also supported the revisions to Footnote ‘b’ to Table 1 of the TPL standards under Project 2010-11. That revision was balloted and approved by the ballot pool in February 2011 and filed with FERC for approval in March 2011. The revised footnote has been incorporated into the current draft of TPL-001-2 as Footnotes 9 and 12 but the Commission, by letter to NERC dated May 17, 2011, has requested NERC to provide supplemental information before the revised Footnote ‘b’ could be approved. In light of FERC’s request and the uncertainty regarding the final provisions of these footnotes, coupled with the ongoing work on Project 2010-17 for the revision of the BES definition and development of an Exception Process and the impact that may have, we respectfully suggest that the drafting team delay further work on TPL-001-2 pending FERC’s ruling on NERC’s petition seeking approval of the transmission planning standards that contain the revised Footnote ‘b’ to Table 1.</p>
<p>Response: The SDT believes that it is important to continue with the approval of this standard. If FERC directs changes based on TPL-002-1, Footnote ‘b’, they will be addressed with this project.</p>		
Hydro One Networks, Inc.	Ballot	<p>Hydro One Networks is casting a negative vote. Other than a few changes related to Footnotes 9 and 12 of Table 1 and VSLs, the other changes in the proposed draft are minor. The concerns of the industry on several</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
	Comment	important issues have not been sufficiently addressed in this draft. For detailed comments please refer to our submission through the on-line comment form.
<p>Response: Please see responses to on-line comments.</p>		
Platte River Power Authority	Ballot Comment	<p>VRF for R2 should be changed back to Medium.</p> <p>VRF for R8 should be changed back to Low.</p>
<p>Response: The SDT is required to follow the VRF guidelines established by NERC and FERC. . No change made.</p>		
American Municipal Power	Ballot Comment	<p>The VSLs appear to have a very low threshold for a SEVERE violation of the individual standard requirements for a planning standard. Please consider the impact of having arbitrarily low thresholds for SEVERE violations. The way the VSLs are set now, an honest interpretation or a small administrative mistake could result in a very high dollar penalty and would be construed as having a high correlation with causing a cascading outage by the media. I think we all just want the appropriate fines or sanctions for a violation and to have minimal fines or sanctions for accidental interpretations or menial paperwork based violations. Please consider another metric or raising the current thresholds.</p>
<p>Response: The SDT is required to follow the VSL guidelines established by NERC and FERC, which apply to both operations and planning on equal footing. No change made.VSL</p>		
Florida Municipal Power Pool	Ballot Comment	<p>A. Spare Equipment, R2.1.5 - The requirement reaches beyond the FERC directive. The directive was: "Accordingly, the Commission directs the ERO to modify the planning Reliability Standards to require the assessment of planned outages consistent with the entity's spare equipment strategy." So, the directive is only to address planned outage, not unplanned outages. Also note that the applicability to GSUs is ambiguous. "Transmission" is defined as: "An interconnected group of lines and associated equipment for the movement or transfer of electric energy between points of supply and points at which it is transformed for delivery to customers or is delivered to other electric systems." Is the "point of supply" the generator terminal, or the GSU high side terminal?</p> <p>B. Table 1, under first heading of "Steady State Only", bullet i is open to interpretation. Many utilities use steady state P-V analyses to study voltage stability and design UVLS systems in apart around those steady</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
		<p>state analyses. Would this bullet essentially eliminate P-V and Q-V studies and the related use of UVLS?</p> <p>C. R7 is not needed and administrative in nature. Instead it should say that an entity can use as evidence another entity's study, but not in the requirement and rather in the measures.</p> <p>D. R8 is ambiguous, does the requirement require submitting the Planning Assessment only after receiving a written request, or automatic distribution to neighboring PCs and TPs without a written request, and to others with a reliability related need following a written request?</p> <p>E. Table 1, under first heading of "Steady State and Stability", bullet c should be removed since it is duplicative of the standard, and not entirely consistent with the standard (e.g., open to interpretation whereas the standard better clarifies how to study protection system operation)</p>
<p>Response: Requirement R2, Part 2.1.5 ensures BES reliability by requiring the planner to assess the system for long lead time items based on the entities' spare equipment strategy. The footnotes in Table 1 clearly define the way transformers are evaluated. No change made.</p> <p>Table 1, Steady State and Stability, Item I does not restrict the use of UVLS since it only addresses equipment disconnected by end-user equipment. No change made.</p> <p>Requirement R7 ensures that there are no gaps between Transmission Planners or the Planning Coordinators that may cause reliability concerns. No change made.</p> <p>Requirement R8 requires the automatic distribution to neighboring Planning Coordinators and Transmission Planners without a written request and to others with a reliability related need following a written request. The SDT believes this is an important consideration and not ambiguous. No change made.</p> <p>Table 1, Bullet c under first heading, is not in conflict with the requirements. The SDT decided to include additional details in Table 1 so that it would have the basic information necessary for the planner to develop their simulations for their studies without always referring back to the requirements language. No change made.</p>		
MRO's NERC Standards Review Forum	No	<p>The NSRF recommends that the VRF for Requirement 8 remain "Low", rather than be changed to "Medium". We do not believe that there is significant risk to the reliability of the BES if an annual Planning Assessment is not distributed to another entities or a documented response to Planning Assessment comments is not provided within 90 days of a request. The findings in an assessment report are not urgent, but address system needs that will emerge over years in the future. In addition, entities with a reliability related need for Planning Assessment information generally have the means to make their own independent planning assessment of adjacent systems or other areas of interest.</p>

Organization	Yes / No	Question 2 Comment
Minnkota Power Coop. Inc.	Ballot Comment	MPC echoes the comments of the MRO NSRS/F
Lincoln Electric System	Ballot Comment	Refer to comments submitted by the MRO NERC Standards Review Subcommittee.
<p>Response: The SDT is required to follow the guidelines established by NERC and FERC.. No change made.</p>		
Tri-State Generation and Transmission Assn., Inc.	No	<p>Many of the sub-requirements of R2 do not warrant high risk VRFs, yet violation of any R2 sub-requirement would result in a “High Risk Factor” violation assessment. We believe that having so many sub-requirements can result in inaccurate overall severity classification. For example, skipping one study defined in R2.1.2 (Planning Assessments) for a particular time frame or load level would probably not result in a direct actual degradation in system performance, but would still result in a High Violation Risk Factor.</p>
<p>Response: The SDT is required to follow the VRF guidelines established by NERC and FERC, which apply to both operations and planning on equal footing.. No change made.</p>		
Muscatine Power and Water	No	<p>MP&W would like to recommend that the VRF for Requirement 8 remain “Low”, rather than “Medium.” It is our belief that there is not a significant risk to the reliability of the BES if an annual Planning Assessment is not distributed to another entities or a documented response to Planning Assessment comments is not provided within 90 days of a request. This is more administrative in nature. The findings in an assessment report are not urgent, but address system needs that will emerge over years in the future. Additionally, entities with a reliability-related need for Planning Assessment information generally have the ability to perform their own independent planning assessment of adjacent systems or other areas of interest.</p>
American Transmission Company, LLC	No	<p>ATC recommends that the VRF for Requirement 8 remain “Low”, rather than be changed to “Medium”. ATC does not believe that there is significant risk to the reliability of the BES if an annual Planning Assessment is not distributed to another entities or a documented response to Planning Assessment comments is not provided within 90 days of a request. The findings in an assessment report are not urgent, but address system needs that will emerge over years in the future. In addition, entities with a reliability related need for Planning Assessment information generally have the means to make their own independent planning assessment of adjacent systems or other areas of interest.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
Electric Reliability Council of Texas, Inc.	No	ERCOT ISO believes that the VRF for R8 should be “low”. The distribution of the Planning Assessment is administrative in nature, the failure to distribute the Planning Assessment does not necessarily equate to not communicating the content of the assessment, and the consequence of not distributing the Planning Assessment does not immediately impact the reliability of the BES; thus it does not warrant a ‘Medium’ risk factor.
<p>Response: The SDT is required to follow the VRF guidelines established by NERC and FERC. No change made.</p>		
ReliabilityFirst	No	<p>ReliabilityFirst generally agrees with the Violation Risk Factors (VRFs) but disagrees with the Violation Severity Levels (VSLs) for the following reasons:</p> <ol style="list-style-type: none"> 1. VSL for R1a. Under the last “Severe” VSL, the word “latest” should be removed to be consistent with the language in Requirement 1. This is a violation of the FERC Guideline 3: “Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement” 2. VSLs for R2a. To be consistent with the language in Requirement 2, suggest modifying the last “Severe” VSL to state “The responsible entity failed to prepare an annual Planning Assessment of its portion of the BES” 3. VSLs for R3a. Under the last VSL under the “High” category, the word “perform” should be replaced with “simulate” to be consistent with the requirement. (e.g. “The responsible entity did not simulate Contingency analysis as described in Requirement R3, Part 3.3.”) 4. VSL’s for R4a. Under the last VSL under the “High” category, the word “perform” should be replaced with “simulate” to be consistent with the requirement (e.g. “The responsible entity did not simulate Contingency analysis as described in Requirement R4, Part 4.3.”). 5. VSLs for R6a. To be consistent with the language in Requirement 6, suggest modifying the “Severe” VSL to state “The responsible entity failed to define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions, as described in Requirement R6.” 6. VSLs for R7a. Suggest adding the following language to the end of the “Severe” VSL; “for the Planning Assessment”, to be consistent with the requirement. 7. VSL for R8a. Under all four categories of VSLs, any reference to “Planning Assessment” should be changed to “Planning Assessment results” to be consistent with the language in Requirement 8 (or more appropriately, the term “results” should be removed from Requirement 8). This is a violation of the FERC

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment		
		<p>Guideline 3: “Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement”</p> <p>b. Under the “Lower” VSL, it is unclear why there is a 30 day timeframe for the first VSL, while the “Moderate”, and “High” VSLs have a 10 day timeframe. Based on FERC recommendations, suggest making the timeframe for all four VSL s, 10 day increments.</p> <p>c. VSLs need to be developed to deal with a violation of Part 8.1 (i.e. the PC or TP failed to provide a documented response to that recipient within 90 calendar days of receipt of those comments)</p>		
<p>Response: 1. The SDT has corrected the language used as shown:</p> <p>R1. VSL – Severe (third part): The responsible entity’s System model did not use the latest data consistent with the datathat provided in accordance with the MOD-010 and MOD-012 standards and other sources, including items represented in the Corrective Action Plan.</p> <p>2. The SDT believes that the wording shown must be taken in context and thus is clear. No change made.</p> <p>3. & 4. The SDT believes the word ‘perform’ is consistent with the language used in the requirement. No change made.</p> <p>5. The SDT sees the suggested change as unnecessary and not providing any additional clarity as it is clear that the analysis is part of the Planning Assessment. No change made.</p> <p>6. The entire standard is about the Planning Assessment and the SDT believes that this is clear in the language used. No change made.</p> <p>7. The SDT has made the suggested change as shown below:</p>				
<p>R8 VSL</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 90 days but less than or equal to 120 days following its completion.</p> <p>OR,</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 120 days but less than or equal to 130 days following its completion.</p> <p>OR,</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 130 days but less than or equal to 140 days following its completion.</p> <p>OR,</p>	<p>The responsible entity distributed its Planning Assessment <u>results</u> to adjacent Planning Coordinators and adjacent Transmission Planners but it was more than 140 days following its completion.</p> <p>OR</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
ITC	No	<p>ITC recommends revising R8 VSLs as follows:</p> <p>Lower VSLThe responsible entity distributed its Planning Assessment to known adjacent Planning Coordinators and known adjacent Transmission Planners but it was more than 90 days but less than or equal to 120 days following its completion. OR, The responsible entity distributed its Planning Assessment to functional entities having a reliability related need who requested the Planning Assessment in writing but it was more than 30 days but less than or equal to 40 days following the request.</p> <p>Moderate VSLsThe responsible entity distributed its Planning Assessment more than 30days but less than 60 days after subsequent requests by adjacent Planning Coordinators or adjacent Transmission Planners who were not sent copies upon completion of the Planning Assessment. OR, The responsible entity distributed its Planning Assessment to functional entities having a reliability related need who requested the Planning Assessment in writing but it was more than 40 days but less than or equal to 50 days following the request</p> <p>High VSLs - eliminate this section. i.e., no high VSLs only lower, moderate and severe</p> <p>Severe VSLsThe responsible entity distributed its Planning Assessment to functional entities having a reliability related need, adjacent Transmission Planners and adjacent Planning coordinators who requested the Planning Assessment in writing but it was more than 60 days following the request.</p>
<p>Response: 1. The suggested wording change is not consistent with the language used in the Requirement. Furthermore, the SDT does not believe that the word 'known' is necessary in this regard. No change made.</p> <p>2. The suggested wording is not consistent with the language used in the requirement. Furthermore, the increment suggested would violate established guidelines. The SDT is required to follow the VSL guidelines established by FERC. No change made.</p> <p>3. When dealing with incremental times in VSLs, the established guidelines indicate that all 4 types of VSL should be utilized. No change made.</p> <p>4. The SDT believes the suggested change makes the VSL less clear. No change made.</p>		
Manitoba Hydro	No	<p>-The language "latest data" is used in the Severe VSL for R1, however "latest" was removed from R1 and M1. "Latest" should also be removed from the Severe VSL for consistency.-What is the rationale for changing the preparation of the Planning</p>
<p>Response: The SDT has corrected the language used as shown:</p> <p>R1. VSL – Severe (third part): The responsible entity's System model did not use the latest data consistent with the datathat provided in accordance with the</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
MOD-010 and MOD-012 standards and other sources, including items represented in the Corrective Action Plan.		
National Grid	No	R 2.0 We recommend that the VRF for this Planning Requirement remain at “Medium”. The risks associated with Planning Requirements have a longer time horizon for corrective action than, for example, those risks associated with much shorter Operational time frames.
Response: The SDT is required to follow the VRF guidelines established by NERC and FERC. No change made.		
Independent Electricity System Operator	No	See our response to Q1.
Response: See response to Q1.		
Consumers Energy	Ballot Comment	We agree with comments submitted by MISO
MISO	No	Regarding Requirement 8, we do not believe that there is significant risk to the reliability of the BES if an annual Planning Assessment is not distributed to another entity or if a documented response to Planning Assessment comments is not provided within 90 days of a request. Requirement 8 is an administrative requirement that adds little to improve reliability. We recommend that the VRF for Requirement 8 remain “Low”, rather than be changed to “Medium”.
Response: The SDT is required to follow the VRF guidelines established by NERC and FERC. No change made.		
New York Independent System Operator	No	Requirement 8 is an administrative burden that adds no value to reliability. Comments have been provided on several past drafts highlighting this effect. The revisions made to the VRF and VSL for Requirement 8 further exacerbate this burden. One could conclude from observation of the VSLs and VRFs, that Requirement 8 was the most important requirement of TPL-001-1. Many Planning Coordinators and Transmission Planners have stakeholder processes that govern participation and notification. Further, FERC Order 890 requires stakeholder participation and transparent processes.
Response: The SDT is required to follow the VRF guidelines established by NERC and FERC.. No change made.		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes / No	Question 2 Comment
Ameren	No	<p>The VRF for Requirement R8 should remain Low. There is no significant risk to the reliability of the BES if a Planning Assessment is not distributed to another entity, or if a documented response is not provided within 90 days of a request.</p> <p>The assignment of some VRFs are inconsistent with the importance of the requirements. R2 requires the development of an assessment and it is determined to have a high VRF. However, R3 and R4 require that studies be performed and these studies are determined to have a medium VRF. Performing the studies is essential to developing an assessment and more important to maintaining reliability. If the VRFs for R3 and R4 are correct, then the VRF for R2 should be no higher than medium.</p> <p>The VRF for R5 to develop a steady-state voltage criteria is determined to be medium. However, the VRF for R6 to develop instability criteria is determined to be low. If the VRF for R6 is correct, then the VRF for R5 should also be low.</p>
<p>Response: The SDT is required to follow the VRF guidelines established by NERC and FERC. No change made.</p> <p>The SDT agrees that studies are essential to the Planning Assessment but believes that the Planning Assessments are more than just the studies. For example, under the correct set of circumstances, an entity can use past studies in their Planning Assessment. Therefore, the SDT believes that the VRFs assigned are correct and in adherence with established guidelines. No change made.</p> <p>The SDT believes that having the criteria (Requirement R5) is more important for the reliability of the BES than documenting the methodology (Requirement R6). No change made.</p>

3. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: Several commenters stated that the SDT failed to address significant concerns and that only minor changes were made from the prior draft. The SDT believes that some stakeholders based their review on a red-line document of the TPL standard which only describes changes made following the Quality Review (QR) team review of the standard; shown as a red-line document http://www.nerc.com/docs/standards/sar/tpl-001-2_redline_to_last_posted_110415.pdf. A complete and thorough red-line of all changes made from the prior 3/01/10 ballot period to the version posted on the most recent ballot (concluded on 5/31/11) was posted and communicated after the start of the last comment period. A number of changes were made in response to industry feedback prior to the latest ballot. Those changes can be viewed at: http://www.nerc.com/docs/standards/sar/TPL-001-2_Redline_to_last_balloted.pdf.

A number of commenters indicated they cast a negative vote and recommended the SDT delay further work on TPL-001-2 pending FERC's ruling on the revised Footnote 'b' to Table 1 found in the existing TPL standards. The SDT believes concerns in process efficiency related to this project and FERC's on-going review of the revised footnote 'b' should not be the sole reason for a negative vote on the new proposed TPL standard and that an entity's vote should be based on the technical merits of the standard. The SDT has taken care to ensure footnotes 9 and 12 in combination are written consistently with footnote 'b'. The SDT encourages that any negative ballot based solely on FERC's pending ruling on footnote "b" be revisited.

Some commenters stated they find the new standard to be poorly organized and too prescriptively written and that the existing standards are preferred over the proposed TPL-001-2. The SDT and others in industry, as evidenced by the 74% ballot approval, hold a different opinion in regard to the standard. The SDT believes the comments of one stakeholder well articulate its view of the standard: "The SDT, Observers, and the Industry as a whole have put a tremendous amount of thought and work into the development of this latest draft. While nobody should claim that this latest version is perfect, it is far clearer, more in tune with current industry needs, and much improved compared to the existing approved Standards that it will replace." The SDT believes many important improvements in transmission planning are driven by the proposed TPL-001-2 that will further improve reliability of the Bulk Electric System.

A few commenters questioned the term "non-redundant relay" as used in planning event P5 and asked the SDT to clarify a distinction between a "back-up relay" and a "redundant relay" and proposed the SDT provide a definition for the term "non-redundant". The SDT clarifies that redundant means 'duplicate capability resulting in the same outcome.' A redundant relay is not the same as back-up relaying capability which may result in more Facilities being removed for failure of the primary/redundant relay to operate as designed. The SDT believes this concept is widely understood by most in industry and does not see the need for a NERC Glossary Definition.

Several commenters noted that the standard makes use of new capitalized "defined" terms, yet the definitions proposed in previous drafts were removed from the most recent draft of TPL-001-2. The SDT clarified that two previously proposed

definitions that were part of this project were moved to another standard development project – Project 2010-10, titled “FAC Order 729”. The two definitions, “Near-Term Transmission Planning Horizon” and “Year One” were approved by the NERC Board of Trustees on January 24, 2011.

Some commenters indicated that the standard’ Implementation Plan should be extended to permit a full 5-years implementation of any Corrective Action Plans required due to short circuit studies. The commenters indicate that these studies are not presently covered by a NERC Reliability Standard and they see this as a significant “raising of the bar” as characterized by other new requirements. The SDT clarified that while a short circuit study requirement is new to mandatory enforceable standards, the SDT does not believe the short circuit study requirements present a significant “raising of the bar” for industry and that good utility short circuit practices are already in place to ensure safe operation of equipment. No extension in the Implementation Plan was made in regard to short circuit studies.

Several commenters stated an opinion that Requirement R1, Part 1.1.2 indicating the models maintained by the Transmission Planners should reflect “known outages ... with a duration of at least 6 months”, are more appropriately dealt with in the operational studies rather than planning studies and that the item should be removed from the standard. The SDT disagrees with the view that outages of 6 months or more should only be reviewed in the operations timeframe. Such an outage could be for an upcoming construction project requiring certain Facilities to be removed from service for long durations of time one or more years in the future and those situations should be evaluated with sufficient lead time to determine any vulnerabilities and development of sufficient Corrective Action Plans as required. The SDT retained the requirement in the standard.

A number of commenters stated that they believed that there was an inconsistency between Requirement R2, Parts 2.1 and 2.2, since qualified past studies were not allowed for the Long-Term Transmission Planning Horizon case. The SDT clarifies that the requirement to conduct a current annual study for one of the study years in the Long-Term Transmission Planning Horizon is intentional to drive earlier identification of potential Transmission performance limitations and earlier development of Corrective Action Plans (CAP). The study results can be used as qualified past studies as they advance to later years, including moving to the Near-Term Transmission Planning Horizon.

Several commenters stated that they believed that Requirement R2, Part 2.1.5 was ambiguous since it was not clear that the planner did not have to include multiple outages of long lead time components simultaneously. The SDT explained that Requirement R2, Part 2.1.5 does not require simultaneous outages of multiple long lead time components.

Some commenters expressed concerns with Requirement R2, Part 2.4.1 since they were concerned with the ability of planners to adequately model the dynamic behavior of Load. The SDT explained that the “aggregate” dynamic Load model may include high-level assumptions on Load profiles for industrial, commercial, and residential Loads that are applied generically across the planning area study based on the planner’s engineering judgment and system knowledge. The model is not required to be “bus” specific.

The SDT appreciates the concern raised by multiple commenters in regard to the inclusion of the 2nd bulleted item of Requirement R3, Part 3.3.1 that states the steady-state Contingency analysis should include subsequent “Tripping of

Transmission elements where relay loadability limits are exceeded". The commenters believe this concern is addressed by PRC-023 and should be removed from the standard. The SDT believes the item is warranted and that TPL studies may earlier identify and flag relay setting concerns based on required Long-Term Transmission Planning Horizon studies. Within the TPL standard, such a concern would have a Corrective Action Plan that would address the issue which would also meet the expectations of PRC-023. The SDT sees this as a defense in depth approach.

A number of commenters expressed concern that Requirement R7 was administrative and was not required. The SDT explained that it believes that the requirement is necessary to ensure that there are no gaps created between the Transmission Planners and the Planning Coordinators when they determine their individual responsibilities.

Several commenters stated that they had concerns with Requirement R8. These concerns are that the requirements create excessive work and should include time limits on requesting the Planning Assessment, are ambiguous, and should include the ability to post the Planning Assessment. The SDT explained that the requirements are only to distribute the Planning Assessment, which should not require a large amount of work, and the requirements are clear that the planners must distribute to adjacent Transmission Planners and Planning Coordinators and others with a reliability need. The SDT further explained that posting the Planning Assessment could meet the requirement to distribute.

Several commenters stated that they believed that Table 1, P2-1 was inconsistent with Footnote 7. The SDT explained that Footnote 7 was included to clarify that "Opening a line section without a fault" could include, but does not always, creating a radial line section with Load and that the planner must evaluate this situation as a part of P2-1.

No requirements were changed as a result of comments received. However, two bulleted items were marked as bullets incorrectly and that formatting has been corrected.

3.1.1 Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2 Tripping of Transmission elements where relay loadability limits are exceeded.

4.3.1.1 Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2 Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3 Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
James A. Maenner	Ballot Comment	The medium VRF for R8 should remain at low. Not sharing planning assessments with other entities within 90 days doesn't create a serious or imminent threat to the BES.
<p>Response: The change to a Medium VRF resulted from the Quality Review (QR) conducted by the independent QR team prior to the last ballot. This requirement is seen as more than simply an administrative response to a request but rather a proactive step required of the applicable planner to share results of its system assessment which may include and reflect potential system impacts to neighboring systems. The SDT is required to follow the VRF guidelines established by NERC and FERC. No change made.</p>		
San Diego Gas & Electric	Ballot Comment	Clarity of this standard is getting worse. Our earlier comments did not seem impacting. At this point, we believe the existing TPL-001-0.1, TPL-002-0a, TPL-003-0a and TPL-004-0 provide much better clarify for us to comply with the TPL standards.
<p>Response: The SDT respectfully disagrees with your view. According to results of the last ballot, 74% of the ballot pool support the proposed standard. The SDT believes the standard clarifies a number of expectations and that appropriate changes have been made to further improve the future planning and review of the Bulk Electric System's ability to reliably serve users of the system. No change made.</p>		
Western Electricity Coordinating Council	Ballot Comment	It is unknown at this time what the outcome of the FERC request for additional information related to footnote B will be, but if it results in changes to the language of footnote B, that may change our support for this standard.
Salt River Project	Ballot Comment	Previous TPL Standard balloting included the FERC Order that clarified footnote 'b', regarding the planned or controlled interruption of electric supply for an N-1 situation. In SRP's view, a Registered Entity's Board of Directors, state Utilities Commission, and/or its customers should determine what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining Affirmative vote.
Public Utility District No. 1 of Chelan County	Ballot Comment	Previous TPL Standard balloting included the FERC Order that clarified footnote 'b', regarding the planned or controlled interruption of electric supply for an N-1 situation. In our view, board of directors/Public Utility should have the determination what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.
Snohomish County PUD No. 1	Ballot	Previous TPL Standard balloting included the FERC Order that clarified footnote 'b', regarding the planned or

	Comment	controlled interruption of electric supply for an N-1 situation. In our view, a Registered Entity’s Board of Directors, Utility Commission, and/or its customers should determine what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.
Public Utility District No. 1 of Chelan County	Ballot Comment	Previous TPL Standard balloting included the FERC Order that clarified footnote ‘b’, regarding the planned or controlled interruption of electric supply for an N-1 situation. In our view, board of directors/Public Utility should have the determination what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.
Clark Public Utilities	Ballot Comment	Previous TPL Standard balloting included the FERC Order that clarified footnote ‘b’, regarding the planned or controlled interruption of electric supply for an N-1 situation. In our view, the utility’s elected board of commissioners should have the determination what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.
<p>Response: The SDT has taken care to ensure consistency in footnote 12 (and footnote 9) with the prior footnote ‘b’ revision supported by industry, approved by the NERC Board of Trustees and submitted for regulatory approval. No change made.</p>		
Imperial Irrigation District		<p>Previous TPL Standard balloting included the FERC Order that clarified footnote ‘b’, regarding the planned or controlled interruption of electric supply for an N-1 situation. In our view, board of directors/Public Utility should have the determination what level of service is acceptable and with what associated cost. This view is captured in footnote #12 of Table 1 in the TPL Standard and will be crucial to maintaining an Affirmative vote.</p> <p>1. R2 (2.5): The value of assessing system stability for years 6-10 is questionable. Stability studies should be conducted for new generation interconnections or for planned major transmission system improvements that have regional impact.</p> <p>2. R8 requirement to distribute all Planning Assessment results to adjacent PCs and TPs are excessive and cumbersome. Regarding R8, IID suggest the following languages: Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners in accordance with the overseeing Reliability Coordinator requirements. Any functional entity that has a reliability related need and submits a written request for the Planning Assessment results, the Transmission Planner and Planning Coordinator shall provide the latest Planning Assessment</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		results within 30 days of such request.
<p>Response: The SDT has taken care to ensure consistency in footnote 12 (and footnote 9) with the prior footnote ‘b’ revision supported by industry, approved by the NERC Board of Trustees and submitted for regulatory approval. No change made.</p> <p>Regarding Requirement R2, Part 2.5, the SDT believes the requirement as written meets your perspective. For the long-term period, the stability assessment is only required to address “... the impact of proposed material generation additions or changes in that timeframe ...”. No change made.</p> <p>Regarding Requirement R8, the SDT disagrees that the requirements for distributing assessment results should be based on requirements of the Reliability Coordinator. The Reliability Coordinator is primarily focused on real-time issues/concerns not planning horizon timeframes. The SDT does not see this requirement as overly burdensome as the results could be emailed to multiple entities in a single notification. Additionally, we do not see Requirement R8 as excessive as we believe it is important to communicate assessment results with others in industry whose systems for which they are responsible for may be impacted by the host analysis being communicated. No changes made.</p>		
Gainesville Regional Utilities	Ballot Comment	I do have one point of concern for your consideration; This standard does raise the bar in some areas, most notably for an entity the size of GVL it applies performance requirements for long lead equipment emergency replacement. For example if we don't have the ability to replace a transformer at Parker within a few months of failure, then we would have to demonstrate that we can meet many (but not all) of the same performance criteria without the transformer that we can with the transformer.
<p>Response: The commenter is referring to expectations stated in Requirement R2, Part 2.1.5 related to a spare equipment strategy regarding the potential unavailability of long lead time equipment that could be out of service for a year or more in the absence of a spare replacement. The SDT believes it has appropriately limited the analysis to address Planning Events P0, P1, and P2 as stated in Table 1. No change made.</p>		
Beaches Energy Services	Ballot Comment	My biggest concern is the spare transformer issue. Beaches Energy Services is fine because our Transmission Planner (FMPPA) actually run the assessments proposed in the new standard and we have excess transformer capacity; but, I'm concerned for other small entities. Essentially, the requirement will likely be interpreted as requiring us to meet the loss of a Bulk Electric System transformer, plus another contingency (two contingencies) to the same performance criteria as a single contingency, if we don't have a spare. This seems discriminatory to small entities.
<p>Response: The commenter is referring to expectations stated in Requirement R2, Part 2.1.5 related to a spare equipment strategy regarding the potential unavailability of long lead time equipment that could be out of service for a year or more in the absence of a spare replacement. The SDT believes it has appropriately limited the analysis to address Planning Events P0, P1, and P2 as stated in Table 1. Any organization – large or small - meeting functional entity</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
<p>registration obligations has the potential to impact the Bulk Electric System and their assessments must include appropriate spare equipment strategies. No change made.</p>		
Hydro One Networks, Inc.	Ballot Comment	<p>Hydro One Networks is casting a negative vote. Other than a few changes related to Footnotes 9 and 12 of Table 1 and VSLs, the other changes in the proposed draft are minor. The concerns of the industry on several important issues have not been sufficiently addressed in this draft. For detailed comments please refer to our submission through the on-line comment form.</p>
<p>Response: The SDT believes the commenter's response is based on their review of red-line document of the TPL standard which only describe changes made following the Quality Review (QR) team review of the standard which was conducted prior to the last ballot. That red-line was shown as http://www.nerc.com/docs/standards/sar/tpl-001-2_redline_to_last_posted_110415.pdf. A complete and thorough red-line of the TPL standard showing all changes made from the prior 3/01/10 ballot period to the version posted on the most recent ballot (concluded on 5/31/11) was posted during the last comment/ballot period. A number of changes were made in response to industry feedback prior to the last ballot. Those changes can be viewed at: http://www.nerc.com/docs/standards/sar/TPL-001-2_Redline_to_last_balloted.pdf. The SDT's response to input provided by the on-line comment form is addressed in responses to Q1 and Q2 above. No change made.</p>		
Hydro-Quebec TransEnergie	Ballot Comment	<p>These are the two major concerns : * In Table 1 footnote 3 : Again, the definition of EHV facilities should be changed to something like : Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as those representing the backbone of the System, generally at voltage greater than 300 kV, and high voltage (HV) Facilities defined as those not representing the backbone of the System, as determined by the Planning Coordinator and approved by Regional Entity. *</p> <p>In Table 1 b : "Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0". We should also add Firm Transmission Services Loss is also acceptable (particularly in P1 Loss of a single pole of a DC line for which the transfer is reduced accordingly to the remaining pole capability). "</p>
<p>Response: In regard to Table 1 footnote 3, the SDT respectfully disagrees and believes the footnote is clear in regards to what subset of Bulk Electric System Facilities are classified as EHV and that the remaining fall to HV Facilities. Anything not deemed Bulk Electric System by a Regional Entity is outside of the scope of footnote 3 and the footnote clarifies that Table 1 sometimes has unique performance requirements depending on the event studied. The SDT believes the categorization is correct. No change made.</p> <p>The SDT disagrees that Firm Transmission Service (FTS) may be interrupted for all events. The events where the interruption of FTS is not permitted are shown with a "No" in the column titled "Interruption of Firm Transmission Service Allowed", however, footnote 9 clarifies that interruption of Firm Transmission Service</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
<p>can be used as both a corrective action and system adjustment as permitted within Table 1. For the specific issue raised, loss of a single pole of a DC line, to the extent the availability of the DC pole is a condition of the transfer being viable, footnote 4 may also address the commenter's concern. No change made.</p>		
<p>Independent Electricity System Operator</p>	<p>Ballot Comment</p>	<p>IESO is generally supportive of the draft of TPL-001-2 as evidenced by our previous AFFIRMATIVE vote during the last ballot. Further, IESO also supported the revisions to Footnote 'b' to Table 1 of the TPL standards under Project 2010-11. That revision was balloted and approved by the ballot pool in February 2011 and filed with FERC for approval in March 2011. The revised footnote has been incorporated into the current draft of TPL-001-2 as Footnotes 9 and 12 but the Commission, by letter to NERC dated May 17, 2011, has requested NERC to provide supplemental information before the revised Footnote 'b' could be approved. In light of FERC's request and the uncertainty regarding the final provisions of these footnotes, coupled with the ongoing work on Project 2010-17 for the revision of the BES definition and development of an Exception Process and the impact that may have, we respectfully suggest that the drafting team delay further work on TPL-001-2 pending FERC's ruling on NERC's petition seeking approval of the transmission planning standards that contain the revised Footnote 'b' to Table 1.</p>
<p>Response: The SDT believes IESO's concerns in process efficiency related to this project and FERC's on-going review of the prior submittal of a revised footnote 'b' should not be the sole reason for a negative vote on the new proposed TPL standard and that IESO's vote should be based on the technical merits of the standard. The SDT encourages IESO to revisit its negative ballot position during the recirculation ballot. As stated in the comment provided, IESO finds footnotes 9 and 12 to be written consistently with footnote 'b' and if IESO supported footnote 'b', the SDT encourages continued support of the issue in the new proposed TPL-001-2 and doing so shows support of the standard on its technical merits. No change made.</p>		
<p>Lakeland Electric</p>	<p>Ballot Comment</p>	<p>LAK appreciates the hard work of the Standard Drafting team and applauds the significant improvement of clarity of the draft standard. FMPA believes we are almost there, but, there are a number of issues left to resolve. Issues that Cause FMPA to Recommend a Negative Vote A. Spare Equipment, R2.1.5 - The requirement reaches beyond the FERC directive. The directive was: "Accordingly, the Commission directs the ERO to modify the planning Reliability Standards to require the assessment of planned outages consistent with the entity's spare equipment strategy." So, the directive is only to address planned outage, not unplanned outages.</p> <p>Also note that the applicability to GSUs is ambiguous. "Transmission" is defined as: "An interconnected group of lines and associated equipment for the movement or transfer of electric energy between points of supply and points at which it is transformed for delivery to customers or is delivered to other electric systems." Is the "point of supply" the generator terminal, or the GSU high side terminal?</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>B. Table 1, under first heading of "Steady State Only", bullet i is open to interpretation. Many utilities use steady state P-V analyses to study voltage stability and design UVLS systems in apart around those steady state analyses. Would this bullet essentially eliminate P-V and Q-V studies and the related use of UVLS?</p>
<p>Response: The SDT respectfully disagrees that the Commission directive regarding a spare equipment strategy is limited to planned outages. In Order 693, Par 1725, the Commission states in its discussion “Thus, if an entity’s spare equipment strategy for the permanent loss of a transformer is to use a “hot spare” or to relocate a transformer from another location in a timely manner, the outage of the transformer need not be assessed under peak system conditions.” The SDT believes FERC clearly intended the spare equipment strategy to cover a catastrophic loss of such long lead-time equipment. Further, the SDT believes it has appropriately limited this review to a small subset of the overall Planning Events – P0, P1, and P2 and for a loss that would be sustained for a year or longer. No change made.</p> <p>The SDT refers the commenter to footnote 5 in regards to the applicability of GSU transformers. The “point of supply” is irrelevant in regards to planning a Transmission system for potential generation loss. The applicable generation is any unit deemed to be BES generation supply by the applicable regional entity. No change made.</p> <p>The SDT points out that Table 1 header note “i” applies to steady-state only and is intended to prevent any reduction in non-consequential Load due to what the planner believes to be sensitive Load loss that may drop out as voltage declines. It is the understanding of the SDT that most utilities only reflect or account for such reduction in Load in the transient timeframe and that planning decisions based on steady-state analysis would appropriately account for serving the non-consequential Load unless subject to interruption per that studied planning event. The bullet does not eliminate P-V or Q-V studies nor does it prohibit use of UVLS as a mitigating action where non-consequential load interruption is permitted. No change made.</p>		
New Brunswick Power Transmission Corporation	Ballot Comment	Foot Note 12: Rather than requiring planning entities to have a open and transparent planning stakeholder process, which could require significant costs and administration, the foot note should focus on ensuring that affected loads/entities are aware of the possible risks of load loss and alternatives and provide for affected stakeholder feedback
<p>Response: The SDT believes the open and transparent stakeholder process described by footnote 12 provides an efficient platform for which the affected end-users and other registered entities would be made aware of instances where non-consequential Load loss is being considered as a Corrective Action Plan and provides the best opportunity for feedback. The process envisioned is already in place in various areas across the various Interconnections in which the NERC Reliability Standards are enforceable. No change made.</p>		
Powerex Corp.	Ballot Comment	Powerex has submitted a negative ballot for Draft #6 of Standard TPL-001 because Powerex has concerns regarding Footnotes 9 and 4 that need to be addressed. Details of our concerns are summarized below.

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>Background: The work that transmission planners do to ensure Firm Transmission Service is tremendously important for the reliability of the Bulk Electric System and forms a key part of the foundation upon which system operators and energy market participants interact. As a Purchasing-Selling Entity, Powerex is primarily concerned about Footnote 9 that conditions when interruption of Firm Transmission Service may be allowed. We believe that the goals of maintaining system reliability and enhancing market participation will both be best served if the conditions for interrupting Firm Transmission Service become clear and unambiguous in the TPL-001-2 Standard. In our experience, Transmission Providers have different interpretations of the TPL-001 Performance Table and because of latitude previously granted by Footnote B have different perspectives of when Interruptions of Firm Transfers is acceptable. Below we describe the two interpretations using the language of the proposed TPL-001 standard. Interpretation #1: Following loss of the most critical transmission element under stressed conditions, the transmission provider plans to supply the forecast peak loads and Firm Transmission Service indefinitely. o Typically this is achieved by assuming that the System Operators would, within a few minutes of the P1 Single Contingency, curtail all non-firm transmission service and then arm Special Protection Schemes that could result in Interruption of Firm Transmission Service or Non-Consequential Load Loss in the event of a P6 Multiple contingency. Interpretation #2: Following loss of the most critical transmission element under stressed conditions, the transmission provider plans to supply the forecast peak loads indefinitely but may curtail all Firm Transmission Service within 20 minutes if required. o Typically this occurs on systems where there are no Special Protection Schemes to address P6 Multiple contingencies, consequently, the transmission planners assume that curtailment of all non-firm AND as much Firm Transmission Service as required will occur within ~20 minutes of the P1 Single Contingency because the Operators must prepare their transmission system to withstand the next worst contingency. Currently, Purchasing-Selling Entities must plan for situations where they could see their Firm Transmission Service on certain paths curtailed within 20 minutes of a P1 contingency. The less stringent interpretation of the TPL-001 Performance Table that allowed a P1 contingency to change into a P6 contingency within the same operating hour, has resulted in situations where the Firm Transmission Service for inter-regional transfers face significantly greater risks of interruption than the Firm Transmission Service provided to local Load Serving Entities. Powerex recommends that the Standards Drafting Team revise TPL-001 such that all Transmission Planners will know that they should plan for Firm Transmission Service to be sustained indefinitely following P1 contingencies.</p> <p>Specific Comments on TPL-001-2: Footnote 9: Deviation from the Approved Footnote B Powerex believes that the Footnote B, as approved by the NERC Board of Trustees on February 17, 2011, is more stringent than the previous Footnote B and will have the effect of ensuring that Firm Transmission Service can be sustained indefinitely following P1 contingencies. The key difference of the proposed Footnote 9 is that it adds</p>

Organization	Yes/ No	Question 3 Comment
		<p>the phrase “as a System adjustment” to the approved version of Footnote B. We believe this addition would cause the practice of curtailing Firm Transmission Service within 20 minutes of P1 contingencies to continue. Consequently, we recommend that the proposed Footnote 9 maintain the approved wording as follows: Footnote 9: An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed (deletion)[as] a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch....</p> <p>For consistency, Table 1 should also be modified to remove the Footnote 9 reference from the Initial Condition Column for the P3-Multiple Contingency and P6 Multiple Contingency Categories.</p> <p>Footnote 9: Clarity on what is meant by “Resources obligated to re-dispatch” It is unclear to many parties what is meant by an obligation to re-dispatch. Some interpret this as a right to direct the Source to curtail energy scheduled on Firm Transmission Service. Our belief is that “an obligation to re-dispatch” should correspond to a formal agreement with a Generation Owner, located on the load side of a transmission constraint, to resupply the load that had been receiving energy from a remote source before the Firm Transmission Service was curtailed. Consequently, we recommend that Footnote 9 be revised as follows: Footnote 9: a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch [to ensure uninterrupted energy supply to the Load-Serving Entity(ies)], where it can be demonstrated that Facilities, internal and external to the Transmission Planner’s planning region, remain within applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss....</p> <p>Footnote 4: Conditional Firm Transmission Service Footnote 4: “Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service.” In a sense, offering conditional firm transmission service is analogous to selling land in a known flood plane - this can be a perfectly acceptable option provided all parties involved in current and future transactions can quantify the risks and manage them appropriately. There needs to be coordination between the planners, operators and marketers to ensure that the conditions that could lead to curtailment of Conditional Firm Transmission Service are understood and the associated risks properly managed. We are concerned that in the absence of coordination, specifically additional requirements included in the BAL and INT standards, energy that is scheduled on conditional firm could actually be marketed as firm and as a result the counterparties to some transactions may not be aware of the curtailment risks they could face.</p>
<p>Response: Footnote 9 - The SDT believes that footnote 9 appropriately allows interruption of Firm Transmission Service as both a corrective action to the initial event studied and as a permissible intermediate “system adjustment” when evaluating a multiple Contingency event such as P3 or P6. The key is that there must</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
<p>be no loss of Load and the planner must be able to show that the curtailment is supported by a valid re-dispatch of generation that would be “obligated to re-dispatch.” Therefore, the planner cannot simply re-dispatch units outside the area of control for the transmission system for which it is reviewing – the re-dispatch must be valid and realistic. The commenter indicates an opinion that footnote 9 introduces a difference from the revised footnote ‘b’ because footnote 9 is applied to multiple Contingency planning events P3 and P6 as an intermediate step – system adjustment. However, the SDT believes that footnote ‘b’ is consistent as it does not explicitly distinguish between the two – corrective action or system adjustment following the single Contingency event that may precede a multiple Contingency event. No change made.</p> <p>Footnote 4 – The SDT agrees with the commenter that the specifics of Conditional Firm Transmission service including the potential/rights for curtailments need to be well understood by all parties involved but the SDT has not identified any BES reliability gaps. No change made.</p>		
Tucson Electric Power Co.	Ballot Comment	The definition for Near Term Planning Horizon was deleted, but the formal term is used in other sections such as R2.2.1. There should be a linkage to MOD standard (e.g. 028, 029 & 030) definitions such as 13 months, etc.
<p>Response: Two previously proposed definitions that were part of this project were moved to another standard development project – Project 2010-10 titled “FAC Order 729”. The two definitions, “Near-term Transmission Planning Horizon” and “Year One” were approved by the Board of Trustees on January 24, 2011.</p>		
Western Area Power Administration	Ballot Comment	Standard is improved over previous drafts, but would like to see further changes. Please see suggestions and comments provided on the Official Comment Form.
<p>Response: Please see the SDT’s response to your suggestions in Question 1.</p>		
SERC Planning Standards Subcommittee		<p>R1 does not seem to address issues where data errors have been introduced into the latest model data.</p> <p>Also, R1 and its VSL may be interpreted to exclude the use of past studies.</p> <p>The Implementation Plan should include a five-year delay in the effective date for short circuit studies (R2 parts 2.3 and 2.8) since these studies are not required in the current version 0 standards.</p> <p>The comments expressed herein represent a consensus of the views of the above-named members of the SERC EC Planning Standards Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board, or its officers.</p>
<p>Response: Requirement R1 of the new TPL standard requires the Transmission Planner and Planning Coordinator to maintain System models within its</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>respective area of responsibility. The requirement indicates that information received via MOD-010 and MOD-012 shall be “supplemented by other sources as needed” and to the extent errors and omissions were either discovered by, or brought to the attention of, the Transmission Planner or Planning Coordinator Requirement R1 establishes an expectation that these “other sources” would be utilized to accurately “represent the project System conditions” being studied. No change made.</p> <p>Requirement R1 is applicable to models used for both current and past studies. No change made.</p> <p>Implementation Plan, Short Circuit Studies – While short circuit study requirements may be new in the realm of mandatory enforceable standards, the SDT does not believe that they present a significant “raising of the bar” for industry. The SDT believes that prudent short circuit practices are effectively in place today to ensure safe operation of the equipment. Therefore, no extension in the Implementation Plan was made in regard to short circuit studies.</p>
<p>SPP Reliability Standards Development Team</p>		<p>A5 It would seem that 84 months wouldn't be universally attainable due to different system configurations, terrain, geography, and permitting issues that are required to complete a corrective action plan.</p> <p>In 2.4.1 we would like to see better clarity on what an Aggregate system load model is and how granular it should be. If the answer is a very detailed representation of the load system then it may take a longer time to implement.</p> <p>In section 2.7 we would to see clarification on the sensitivity analysis. Is this in reference to seasonal models and differences in fuel availability? We need more detail on how this is to be done so that it won't be left up to interpretation. We would like for clarification of the planning assessment and who is performing which tasks. We would also like to utilize a regional assessment due to limited resources. Under which criteria should the assessment fall under the regional entity or the individual companies?</p> <p>In section 3.4.1 this type of coordination could be difficult due to other adjacent entities on different schedules and some possibly couldn't have the amount of detail to incorporate into another's processes. We know this is generally covered in coordination of real time operations and wonder if it is appropriate to require this type of coordination in the long term process. Is there already an operational standard that covers this? Would it be better to address this in the operational standards?</p> <p>PC's between regions are already coordinating for long term studies. Should this standard fall more on the back of the PC's rather than the TP</p> <p>Can we get a bright line definition of what apparent impedance swings means?</p> <p>R4.3.1 will the detailed amount of data then be incorporated back into the NERC modeling processes and create a more detailed model with better accuracy?</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>R8 We do not agree that we should provide the assessment to every adjacent PC and TP. We do agree however that if requested by these entities we would provide the assessment. We don't mind sharing information with requestors but would like a longer duration than 30 days due to the fact that we would like to know what type of "reliability need" any entity would have considering that some of the information could be considered CEII. Non disclosure agreements may be needed in order to provide this information.</p>
<p>Response: Effective Date (A5) – The SDT believes the 7 year (84 month) transition to areas where the standard significantly raises planning expectations over the existing standard is more than sufficient for the vast majority of the continent and for most Corrective Action Plans. To the extent additional time is required an entity would need to submit a timely mitigation plan with its Regional Entity organization. No change made.</p> <p>The "aggregate" dynamic Load model may include high-level assumptions on Load profiles for industrial, commercial, and residential Loads that are applied generically across the planning area study based on the planner's engineering judgment and system knowledge. The model is not required to be "bus" specific. No change made.</p> <p>In Requirement R2, Part 2.7, it is stated that a Corrective Action Plan is not required solely for a "single sensitivity study". The standard envisions a portfolio of sensitivity analyses being established for a planning area and the standard does not require Corrective Action Plans for single sensitivity results that may have placed the system in a greater stressed analysis (i.e., heavy system transfers) for its initial (P0) sensitivity model over other models that did not identify performance criteria violations for the same Contingency event studied. No change made.</p> <p>If a Regional Entity acts as your "Planning Coordinator" then tasks between the Planning Coordinator and Transmission Planner are to be defined as part of Requirement R7. The standard does not prohibit the use of valid studies performed by 3rd parties for a given planning area. No change made.</p> <p>In regards to Requirement R3, Part 3.4.1, the SDT envisions that knowledge of the applicable Contingencies on neighboring systems would develop over time and be discovered with the results being distributed in Requirement R8. The SDT believes that this is an important improvement to the planning timeframe analysis and that system information learned in the operations environment should most certainly be considered to the extent it improves the robustness of the Planning Assessment. No change made.</p> <p>Both the registered Transmission Planner and Planning Coordinator have functional entity responsibility for Transmission system planning as defined by NERC's Functional Model. The SDT believes the new TPL-001-2 is appropriately aimed at both throughout the standard. Additionally, Requirement R7 should address the commenter's concern and if greater responsibility can be agreed upon for the Planning Coordinator for a particular area of the continent the standard would not prohibit such a determination. No change made.</p> <p>The "apparent impedance swing" is the trajectory of changes in the apparent impedance seen by a distance relay for various system and fault conditions. In the case contemplated in Requirement R4, Part 4.1.2, it is the trajectory seen by the distance relay for the initial fault and the subsequent generator(s) pulling out of synchronism. If that trajectory were to come within the tripping characteristic of the relay for a sufficient length of time, the relay would cause its associated line</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
<p>to trip. No change made.</p> <p>This standard does not address the studies performed by NERC or its model building practices.</p> <p>The SDT and (based on the recent ballot approval of 74%) the majority of industry support Requirement R8 – no change made.</p>		
MRO's NERC Standards Review Forum		<p>The NSRF recommends that the term, “System” be replaced with “BES” in various places throughout the standard when the reference should not be to the collective generation, transmission, and distribution systems, which is the definition of the NERC Glossary term, “System”. These locations are: R2.1.4, R2.1.5, R2.4.3, R2.6.2, R2.7, R2.7.1, R2.7.4, R2.8.1, R2.8.2, R3.5, R4.5, R5, and R6</p>
Muscatine Power and Water		<p>MP&W recommends that the term “System” be replaced with “BES” in various places throughout the standard when the reference should not be to the collective generation, transmission, and distribution systems. This is the current definition of the NERC Glossary term “System”. The locations where “System” can be found in the Standard are: R2.1.4, R2.1.5, R2.4.3, R2.6.2, R2.7, R2.7.1, R2.7.4, R2.8.1, R2.8.2, R3.5, R4.5, R5, and R6.</p>
<p>Response: Even though the capitalized term “System” includes distribution components, the SDT believes that its usage within this standard is correct because the Reliability Standards apply only to the BES. Therefore, adding additional qualifiers is not needed. No change made.</p>		
BC Hydro		<p>BC Hydro agrees with merging the standards together into one and we feel the new version brings further clarity to the annual planning assessment. BC Hydro would vote Affirmative for bringing clarity, however we do not believe the rewording in Footnote 9 is clear which is why we are voting Negative. Footnote B, as approved by the NERC Board of Trustees on February 17, 2011 was reworded as Foot Note 9 in the proposed TPL 001-2 draft 7 amendment. This rewording still does not clearly define what impact the proposed revision would have on the curtailment of firm transfers in the regional entities.</p>
<p>Response: The equivalent of the revised footnote ‘b’ as approved by the NERC Board of Trustees on February 17, 2011 is addressed by the combination of two footnotes – footnote 9 and footnote 12 – in the new proposed TPL-001-2 standard. The SDT believes that footnote 9 appropriately allows interruption of Firm Transmission Service as both a corrective action to the initial event studied and as a permissible intermediate “system adjustment” when evaluating a multiple Contingency event such as P3 or P6. The reliance on the interruption of Firm Transmission Service in the Planning Horizon is limited in two ways. First, there must be no planned use of firm Load shedding and second, the planner must be able to demonstrate that the curtailment is supported by a valid re-dispatch of generation that would be “obligated to re-dispatch.” Therefore, the planner cannot simply re-dispatch units outside the area of control for the transmission system for which it is reviewing – the re-dispatch must be valid and realistic. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
Entergy Services		Footnote 12 to Table 1 concerning non-consequential load loss should be clarified. The existing language will result in difficulties in proving compliance. Suggested language would be: "Planned or controlled interruption of Demand supplied by Transmission Facilities made temporarily radial as a result of a P1 or P2 event and where the location of the planned loss of Demand is limited to those Transmission Facilities made radial."
<p>Response: The SDT in a separate standards development project - Project 2010-11 TPL Table 1 Order – attempted the radial concept described by the commenter in its revision of footnote 'b' as used in the existing set of TPL standards. The proposed "radial" footnote 'b' was presented for industry ballot from 05/17/10 through 05/27/10 and failed at 63.8%. Following an industry technical conference, the SDT continued to work on footnote 'b' and a revised version was approved by the NERC Board of Trustees on February 17, 2011. The combination of footnotes 9 and 12 consistently apply the industry approved revised footnote 'b' in the new standard. No change made.</p>		
Tri-State Generation and Transmission Assn., Inc.		<p>R1.1 to "System models used for Steady State and Stability Analysis shall represent:" Much of what is in R1.1 is unnecessary for Short Circuit studies. In contrast, there are items not mentioned in R1.1 that are necessary for short circuit studies.</p> <p>R2.1.4 requires sensitivity analysis to study "a range of credible conditions that demonstrate a measurable change". How will the required actions in R2.1.4 be documented or measured, and what is accomplished by performing sensitivity analysis in the context of a system performance assessment?</p> <p>In R2.3, change the first sentence to read "The short circuit analysis portion of the Planning Assessment shall be conducted annually, using one of the cases described in 2.1.1, addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6." There appears to be no reason to perform short circuit studies for all three Near-Term Transmission Planning Horizon cases.</p> <p>R2.4.3 requires sensitivity analysis to study "a range of credible conditions that demonstrate a measurable change". How will the required actions in R2.4.3 be documented or measured, and what is accomplished by performing sensitivity analysis in the context of a system performance assessment?</p> <p>R2.7.1 remove the last bullet. We believe these programs are already factored into the load forecast, as they are associated with resource scheduling and planning load serving, and not transmission planning. In particular, DSM measures would fall under R2.4.1, and the term "new technologies, or other initiatives"</p> <p>The language of Requirement 3 unnecessarily repeats the language of R1 and R2. As now written, R3 states "For the steady state portion of the Planning Assessment, each Transmission Planner and Planning</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1.”</p> <p>R3 We recommend that the introductory language in Requirement R3 be changed to read “The studies in Requirement R2, Parts 2.1, and 2.2 shall be performed using models as defined in Requirement R1 in accordance with the following criteria.”</p> <p>We believe that Requirements 3.1 and 3.4 should be combined into R3.1, eliminating R3.4. It is redundant to have Requirement 3.1 say “perform R3.4”. We recommend that R3.4 be deleted and that R3.1 be replaced with:R3.1 Planning event studies shall be performed in accordance with “Table 1 - Steady State & Stability Performance Planning Events;” and shall be based on a supportable Contingency list.</p> <p>Comment: The content of 3.4.1 was intentionally omitted as it is redundant with R7. Also, the language “...more severe System impacts...” was intentionally omitted as it could be subject to a wide range of interpretations. Similarly, we recommend that R3.5 be deleted and that R3.2 be replaced with:R3.2 Extreme event studies shall be performed in accordance with “Table 1 - Steady State & Stability Extreme Events;” and shall be based on a supportable Contingency list.</p> <p>We recommend the following new requirement be inserted after the revised R3.2 language:Should the extreme event studies identify potential Cascading, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.</p> <p>Comment: As before, the language “...more severe System impacts...” was intentionally omitted as it could be subject to a wide range of interpretations.</p> <p>We recommend removing the second bullet of R3.3.1, “Tripping of Transmission elements where relay loadability limits are exceeded” for the following reasons:1. There is currently no tool to model relay loadability characteristics in Steady State analysis. 2. Requirement R3.3.1 would require inclusion of relay models in modeling data that are not currently provided. MOD-012 does not require impedance or overcurrent relay models to be submitted.3. In Requirement 3.3.1, the second bullet, it is impossible to model complete and accurate relay loadability using present-day steady state simulation tools. At best an individual point could be chosen to model relays based on a selected power factor.</p> <p>We recommend changing the opening text of Requirement R.3.3.2 to say “Simulate the expected automatic or manual operation...”</p> <p>Subrequirement R4.1.2 represents a tremendous increase in dynamic modeling complexity. Modeling relay</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>action during apparent impedance swings would require inclusion of impedance relay models in modeling data that are not required to be submitted in MOD-012. If such modeling is necessary, then the corresponding data requirements need to be addressed in MOD standards.</p> <p>We believe that Requirements 4.1 and 4.4 should be combined into R4.1 as shown below and R4.4 should be deleted. It is redundant to have Requirement 4.1 say “perform R4.4.” We recommend R4.1 language be revised to read as follows:R4.1 Planning event studies shall be performed in accordance with “Table 1 - Steady State & Stability Performance Planning Events;” and shall be based on a supportable Contingency list.Comment: The content of 4.4.1 should be omitted as it is redundant with R7. Also, the language “...more severe System impacts...” should be omitted as it could be subject to a wide range of interpretations.</p> <p>Similarly, R4.5 should be deleted and R4.2 should be replaced with:R4.2 Extreme event studies shall be performed in accordance with “Table 1 - Steady State & Stability Extreme Events;” and shall be based on a supportable Contingency list.</p> <p>We recommend the following new requirement be inserted after the revised R4.2:Should the extreme event studies identify potential Cascading, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the even(s) shall be conducted.</p> <p>Comment: As before, the language “...more severe System impacts...” was intentionally omitted as it could be subject to a wide range of interpretations. Clarify the first bullet in Requirement R4, part 4.3.1 by changing it to “High-speed (less than 1 second) reclosing, where the fault has cleared, and high-speed reclosing into the permanent fault , but in each case only if high-speed reclosing is utilized”.</p> <p>In Requirement R4, part 4.3.1, third bullet, it is impossible to model complete and accurate relay loadability using present-day steady state simulation tools. Existing applications do have impedance relay models, but these models do not model many relay capabilities- for example, non-circular protection regions and load-encroachment. We recommend removing this bullet.</p> <p>The comment statement we made above referring to R4.1.2 also applies to R4.3.1. MOD-012 does not require reclosing relay model data to be submitted. If such modeling is necessary, then the corresponding data requirements need to be addressed in MOD standards. Furthermore, there is not a standard built-in reclosing relay model in current stability simulation tools.</p> <p>Comments regarding Table 1-We assume the headnote i. to Table 1 - “The response of voltage sensitive Load...” - means that studies must not rely on end-user load tripping to meet the performance requirements defined in TPL-001-2 but that it should be modeled (when known) so that its occurrence would be evident.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>We don't see the need to apply Footnote 12 to only certain contingency categories or certain events in categories. Recommend putting the footnote in the column header just as with Footnotes 1, 2, 3, and 4. Recommend changing "utilized" in Measurement M3 to "performed." Recommend changing "utilized" in Measurement M4 to "performed." Modify Measurement M7 to "Each Planning Coordinator shall provide dated documentation on roles and responsibilities of its Transmission Planners, such as..." The deleted phrase, "in conjunction with each of its Transmission Planners," appears to be unnecessary.</p>
<p>Response: Requirement R1, Part 1.1 – The SDT believes that the planners must have the general information in Requirement R1, Part 1.1 in order to conduct the necessary studies for steady state, stability, and short circuit. The requirement states that the planner shall maintain System models, not to have a single model that covers all three categories. The SDT believes that the planner will need the items in Requirement R1, Part 1.1 to develop the smaller set of items that are necessary for their short circuit models. No change made.</p> <p>Requirement R2, Part 2.1.4 – This item requires the planner to show evidence of one or more sensitivity studies which show appreciable change from the prior projected (P0) system condition (pre-sensitivity adjustment). Measurable changes for the revised P0 system condition could be evidenced by line or transformer flows, voltages, a change in dispatch, load increase, etc., assuming the change places additional stress on a portion of the system being reviewed for the sensitivity studied. The sensitivity analysis is important for the applicable entity to better understand their system's vulnerability to alternate "base (P0)" conditions. The intent is to develop a portfolio of potential credible conditions so that the planner better understands potential vulnerabilities. In the Corrective Action Plans (CAP) area of the standard, Requirement R2, Part 2.7, a CAP may be required if a Planning Event shows performance criteria concerns for one or more sensitivity scenarios. No change made.</p> <p>Requirement R2, Part 2.3 – The standard states that the planner shall maintain System models, not to have a single model that covers all three categories - for steady state, stability, and short circuit. It is common within many organizations that separate models are maintained for short circuit analysis since they require breaker configuration details not contained within steady-state load flows. Additionally, short circuit models may not have end-use Load represented but rather emphasis is on system topology, impedance, generation dispatch, fault location etc. No change made.</p> <p>Requirement R2, Part 2.4.3 – same response as Requirement R2, Part 2.1.4 above.</p> <p>Requirement R2, Part 2.7.1 – The SDT disagrees that the last bulleted item which includes use of a rate application or DSM program would be inclusive to the forecasted Load within the model studied. No change made.</p> <p>Requirement R3 – The SDT clarifies that Requirement R2 refers to an "annual assessment" which collectively includes current or past studies, Corrective Action Plans, etc. required for steady-state, stability, and short circuit analysis. Requirement R3 deals with a portion of the overall assessment and is focused on the</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		steady-state “study” requirements for the Near-Term and Long-Term Transmission Planning Horizons. No change made.
		Requirement R3, Part 3.1 – The SDT did not receive any significant industry objection to having Parts 3.1 and 3.4 separated. The proposed change is based on a formatting and style preference and does not address a reliability gap in the standard. No change made.
		Requirement R3, Part 3.2 – The SDT did not receive any significant industry objection to having Parts 3.2 and 3.5 separated. The proposed change is based on a formatting and style preference and does not address a reliability gap in the standard. No change made.
		Requirement R3, Part 3.4.1 and Requirement R7 are uniquely different and not redundant as suggested by the commenter. No change made.
		Requirement R3, Part 3.5 (proposed new 3.2 by commenter) – The commenter finds the term “more severe System impacts” too open to interpretation and suggests a focus on Cascading conditions. The SDT believes the requirement is clear as written and that the statement “more severe System impacts” is used to describe the latitude in engineering judgment afforded to the planner in developing its extreme Contingency list. Action is only required on the subset of items that show the potential for Cascading. No change made.
		Requirement R3, Part 3.3.1, bullet 2 – this does not require an “automatic” modeling feature but rather it could be further subsequent manual analysis performed as needed for a given Planning Event. For example, if a line flow shows >150% loading the planner may need to trip the circuit to see if a stable condition results and what performance criteria issues may be present. To the extent this could be automated through programming the planner may do so at their discretion. No change made.
		For similar reasons stated in the response to Requirement R3, Part 3.5, the SDT does not find the phrase “more severe System impacts” as vague and open to interpretation. No change made.
		Requirement R3, Part 3.3.1 - The SDT language does not require comprehensive relaying models. No change made.
		Requirement R3, Part 3.3.2 - The SDT does not believe the proposed wording changes provide any clarity and finds the item clear as stated. No change made.
		Requirement R4, Part 4.1.2 – The “apparent impedance swing” is the trajectory of changes in the apparent impedance seen by a distance relay for various system and Fault conditions. In the case contemplated in Requirement R4, Part 4.1.2, it is the trajectory seen by the distance relay for the initial Fault and the subsequent generator(s) pulling out of synchronism. If that trajectory were to come within the tripping characteristic of the relay for a sufficient length of time, the relay would cause its associated line to trip. With that explanation, the SDT does not believe the modeling requirements are overly complex or difficult to achieve. No change

Organization	Yes/ No	Question 3 Comment
		<p>made.</p> <p>Requirement R4, Parts 4.1 and 4.4 - The SDT did not receive any significant industry objection to having Parts 4.1 and 4.4 separated. The proposed change is based on a formatting and style preference and does not address a reliability gap in the standard. No change made.</p> <p>Requirement R4, Part 4.5 - the SDT does not believe the proposed wording changes are warranted and finds the item clear as stated. No change made.</p> <p>Requirement R4, Part 4.3.1, first bullet – the SDT does not believe the proposed wording changes are warranted and finds the item clear as stated. No change made.</p> <p>Requirement R4, Part 4.3.1, third bullet – The SDT language in Requirement R4, Part 4.3.1 states “The analyses shall include the impact of subsequent” and does not require comprehensive relaying models. However, it does require that the planner take into account the effects of System Protection on System performance. No change made.</p> <p>Table 1 header note “i” – The SDT notes that this item only applies to steady-state load flow analysis and no assumed shedding of non-consequential sensitive Load is permitted for the steady-state analysis unless it is to be intentionally dropped as part of a Corrective Action Plan where warranted. No change made.</p>
Hydro One Networks Inc.		<p>A. Regarding Requirement 1.1.2, assessment of “known outages... with a duration of at least 6 months”, are dealt with in the operational studies rather than planning studies. In addition, any adverse impact that these outages might have, are mitigated by operational decisions rather than “planning” decisions within a 6-month horizon. It is suggested to move this requirement out of TPL standards and instead include it a relevant operational standards.</p> <p>B. The statement in R 2.1.4, “must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response”, leaves room for very different interpretations by PCs and TPs as to the number and type of required sensitivity studies. Are all interpretations, based on the engineering judgment of the PC and TP, acceptable?</p> <p>C. The language of R 2.1.4 and 2.4.3 allowing to perform one or more sensitivities appears to be inconsistent with the language in R 2.7.2 which requires multiple sensitivities to determine if actions to resolve performance deficiencies are necessary. Will varying only one measurable quantity several times in multiple simulations constitute multiple sensitivity studies or one sensitivity study?</p>

Organization	Yes/ No	Question 3 Comment
		<p>D. The language of Requirement 2.1.5, “spare strategy”, appears to be open-ended regarding the number of permutations to be analyzed. It is suggested to move this requirement out of TPL standard and instead have this issue dealt with in the operational standards.</p> <p>E. In R 2.2, the statement “be supported by the following annual current study, supplemented with qualified past studies” should be replaced with a similar statement in R 2.1 which says: “be supported by current annual studies or qualified past studies”.</p> <p>F. In R 4.1.1, “For planning event P1: No generating unit shall pull out of synchronism” is too restrictive. In many cases a P1 event may result in instability of a small nearby generator without a significant impact on the reliability of BES. The same requirement states that “A generator being disconnected from the System ... by a Special Protection System is not considered pulling out of synchronism”. If rejection of ANY generator by SPS is acceptable, why should instability of a small generator, resulting in its disconnection by its protection without a severe impact on the system, be unacceptable in all circumstances? If this requirement is unchanged, it dictates the addition of an SPS (Generation Rejection) for any unit that might go unstable without any benefit for the reliability of the BES.</p> <p>G. In Table 1, Event 1 of Category P2 and related Footnote 7 (simulation of LEO condition) are not clear (concern with the use of the word “possibly”). If the intension is to simulate LEO condition of tapped lines, this should be clearly stated in the table (without reference to “Opening of a line section” and use of different language in the footnote).</p>
<p>Response: A: The SDT disagrees with the view that outages of 6-months or more should only be reviewed in the operations timeframe. Such an outage could be for an upcoming construction project requiring certain facilities to be removed from service for long durations of time and those situations should be evaluated with sufficient lead time to determine any vulnerabilities and development of sufficient Corrective Action Plans as required. No change made.</p> <p>B. The standard does not mandate the number of sensitivity analyses performed nor the number of adjustments made and engineering judgment of the Transmission Planner and Planning Coordinator is acceptable. No change made.</p> <p>C. Requirement R2, Parts 2.1.4 and 2.4.3 are not inconsistent with Requirement R2, Part 2.7.2. With the various requirements, the planners are required to conduct multiple sensitivities. Therefore, Requirement R2, Part 2.7.2 could be used when the results of these multiple sensitivities identify common concerns. The situation described would could be considered multiple sensitivity studies, if the multiple simulations represent more than one of the studies in Requirement R2, Part 2.1.1 and 2.1.2 or Requirement R2, Part 2.4.1 and 2.4.2. No change made.</p> <p>D. The spare equipment strategy is an important planning aspect to better assist operations. The SDT disagrees that the number of permutations is open-ended. The evaluation is simply a new P0 condition starting with a long lead-time (one year or more) facility removed from service followed by an analysis</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>covering the P0, P1 and P2 studies. No change made.</p> <p>E. The requirement for an annual current steady-state study in the Long-term Transmission Planning Horizon is intentional to drive earlier identification of potential transmission performance limitations and earlier development of Corrective Action Plans. The study results can be used as qualified studies as they advance to later years, including moving to the Near-Term Transmission Planning Horizon. No change made.</p> <p>F. The SDT respectfully disagrees with the commenter. For a P1 single Contingency event, the SDT believes, and a majority of industry stakeholders find it reasonable, that no Bulk Electric System (BES) generation unit be pulled out of synchronism due to the P1 event studied. If the “small” nearby unit is served below threshold kV and MW size limitations set by your Regional Entity to qualify as a BES unit, the unit would not be within scope of the standard. No change made.</p> <p>G. Table 1, footnote 7 – The SDT added the footnote to further explain its intent for P2-1 and to ensure that the planner assess the voltage of a load bus that was on a radial line. The word “possibly” was used since having load on a radial is not always the outcome of opening one end of a line section. No change made.</p>
Arizona Public Service Company		AZPS would like to reiterate its “Affirmative” voting recommendation with regard to the proposed revisions to the Standard. AZPS erroneously entered a “Negative” Standard vote for one of its voting segments.
Transmission Strategies, LLC		The SDT, Observers, and the Industry as a whole have put a tremendous amount of thought and work into the development of this latest draft. While nobody should claim that this latest version is perfect, it is far clearer, more in tune with current industry needs, and much improved compared to the existing approved Standards that it will replace.
Response: Thank you for your support.		
NIPSCO		1.1.2. Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. This is a little confusing to me. Does this mean the outage must last at least six months? Or does this mean at least model outages that last six months or more. If it is the latter then, I'm not sure that is stringent enough. There may be known critical outages occurring over peak that do not last 6 months. If non-consequential load loss is not allowed for loss of one element, then what about the next contingency? Couldn't that result in having to interrupt Firm service? Is that okay as a corrective action plan in the outage coordination horizon? Does this apply to both near-term and long-term planning? If so, we probably need to model additional unplanned potential outages on top of n-1 conditions.

Organization	Yes/ No	Question 3 Comment
		Lastly, in section 2.1.4 should there be a category for high/low wind conditions?
<p>Response: Requirement R1, Part 1.1.2 is related to known existing conditions or known future conditions of facilities being removed from service; i.e., a construction project that requires an existing facility to be de-energized for a period of 6-months or more. This requirement should not be confused with hypothetical situations that could result in an extended loss of a facility. Those situations are the intended purpose of a sound spare equipment strategy. The standard only requires analysis of known or planned outages of 6-months or greater to be included within a P0 system condition. The planner could review shorter duration planned outages as part of its sensitivity analysis portfolio. No change made.</p> <p>The SDT does not believe there is a need to account for a high/low wind condition situation. The intended purpose of this suggested condition within the sensitivity portfolio is not clear. No change made.</p>		
ReliabilityFirst		<p>1. Requirement 8 and 8.1 uses the language of “Planning Assessment results”. This language is not defined in the section of the standard that defines the terms of use. For consistency “Planning Assessment results” should be replaced with “Planning Assessment”.</p> <p>2. Requirement 2.1.5 has statements that are ambiguous. What is considered major transmission equipment? What is an entity’s “spare equipment strategy”? The requirement is not clear as to how many power flow models are required (one per piece of “major transmission equipment” without a spare, or one model with every piece of “major transmission equipment” without a spare being out of service)? As written, if an entity has no “spare equipment strategy” they could be exempt from this requirement.</p> <p>3. We interpret the use of bullet points in Requirement 3.3.1 to mean that either one of the statements can be chosen. This requirement should be written where all the bulleted statements are included in the analyses.</p>
<p>Response:</p> <ol style="list-style-type: none"> The SDT sees no reliability reason or clarity for the change suggested. No change made. Requirement R2, Part 2.1.5 is intended to analyze the removal of a single piece of long lead time equipment (one year or more) to the extent there is no existing spare equipment strategy to provide a means of returning to service (in a less than one year) a comparable replacement. If this condition exists, then the facility (single element) in question must be removed in the model to establish a new P0 system condition and studies must then be run for P0, P1, and P2 for the new system scenario. The spare equipment strategy must be reviewed for the entity's system exposure to catastrophic failures resulting in the long lead-time facility outages, however, only one facility must be removed at a time if the condition exists for multiple facilities. A Transmission Planner may have no spare equipment strategy if they are able to demonstrate they are not responsible for any facilities which they believe could place them in a “long lead-time” scenario. No change made. 		

Organization	Yes/ No	Question 3 Comment
		<p>3. The bulleted items of Requirement R3, Part 3.3.1 were meant to be inclusive. This means that the use of bullets here was incorrect and the items should be numbered elements. This same change was made to Requirement R4, Part 4.3.1.</p> <p>3.3.1.1 Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.</p> <p>3.3.1.2 Tripping of Transmission elements where relay loadability limits are exceeded.</p> <p>4.3.1.1 Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.</p> <p>4.3.1.2 Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.</p> <p>4.3.1.3 Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.</p>
ITC		<p>ITC COMMENTS on TPL-001 vote ITC will reluctantly vote to approve the draft standard. While we have concerns, we are voting to approve this standard because we believe the positive elements outweigh the portions of the draft standard that we object to. It is important that the improved requirements that effectively “raise the bar” over the existing standard should become effective sooner rather than later. A negative vote, which might cause a further delay in implementation of the standard, would be the least desirable outcome. However, we still believe that the VSL that would find that an entity had committed a “severe” violation for failure to distribute its planning assessment to an adjacent Transmission Planner or Planning Coordinator has the potential to overly punish a simple error in oversight. We would agree that willfully withholding an assessment from a neighbor or a valid requestor justifies a severe violation but an administrative or clerical oversight does not. For example, it might escape our attention that an entity, particularly a smaller one, registers as a TP or TP. As far as we know, there is no requirement that a registrant, or even one who de-registers, must notify an “adjacent” TP or PC of their change in status. As written, the standard requires you be found in “severe” violation, even if that new entity fails to notify you of their change in status. You would still be in severe violation even if they later ask for your planning assessment. Even if the standard passes, we request that this VSL be fixed to make the distinction between an administrative error and willful neglect. Our response to question 2 offers a suggested method to do this.</p>
<p>Response: Requirement R8 is an important aspect of the new TPL-001-2 standard to communicate results with neighboring systems and those demonstrating a reliability need. The SDT notes that the VSL Guidelines require a Severe VSL for each and every requirement but encourages graded (multiple level) VSLs where</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>possible. In regard to Requirement R8, the SDT has established four VSLs. It is noted that an entity can be up to 120 days (~ 4 months) late in its delivery of the information and remain in the Lower VSL category before being exposed to the Severe VSL category. The 10 day increment in the other VSL categories, above the 120 day Lower VSL, conforms to NERC's VSL Guidelines. See the response to your suggested VSL changes in Question 2, however, it is noted that no changes were made to the Requirement R8 VSLs. No change made.</p>
South Carolina Electric and Gas		<p>R1 does not seem to address errors in data that have been introduced in the latest model data. In addition, R1 and its VSL may be interpreted to exclude the use of past studies.</p> <p>The Implementation Plan should include a five year delay in the effective date for short circuit studies for parts 2.3 and 2.8 of R2 because these studies are not required in the current Version 0 standards.</p>
		<p>Response: Requirement R1 of the new TPL-001-2 standard requires the Transmission Planner and Planning Coordinator to maintain System models within its respective area of responsibility. The requirement indicates that information received via MOD-010 and MOD-012 shall be "supplemented by other sources as needed" and to the extent errors and omissions were to be discovered by, or brought to the attention of, the Transmission Planner or Planning Coordinator Requirement R1 establishes an expectation that these "other sources" would be utilized to accurately "represent the project System conditions" being studied. No change made.</p> <p>Requirement R1 is applicable to models used for both current and past studies. No change made.</p> <p>Implementation Plan, Short Circuit Studies – While short circuit study requirements may be new in the realm of mandatory enforceable standards, the SDT does not believe that they present a significant "raising of the bar" for industry. The SDT believes that prudent short circuit practices are effectively in place today to ensure safe operation of the equipment. Therefore, no extension in the Implementation Plan was made in regard to short circuit studies.</p>
Manitoba Hydro		<p>-Why was the Near Term Transmission Planning Horizon definition moved to the Glossary prior to TPL-001-2 approval?-</p> <p>The definition of Non-Consequential Load Loss should not contain '(2) the response of voltage sensitive Load' because voltage sensitive</p>
		<p>Response: Two previously proposed definitions that were part of this project were moved to another standard development project – Project 2010-10 titled "FAC Order 729". The two definitions, "Near-term Transmission Planning Horizon" and "Year One" were approved by the Board of Trustees on January 24, 2011.</p> <p>The statement related to the "Non-Consequential Load Loss" definition is incomplete. No change made.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
National Grid		<p>R 1.1.2 We recommend the known facility outage duration be defined as facility outage durations lasting at least twelve months.</p> <p>R 1.1. (page 4) System models shall represent: 1.1.1. Existing Facilities 1.1.2. Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six twelve months. 1.1.3</p> <p>R 2.1.4 We recommend that this requirement be eliminated. We do not see the value of this additional analysis when the number, type and severity of the sensitivity tests are not well defined. These tests are then used to define Corrective Action Plans in cases only where multiple tests show performance deficiencies.</p> <p>R 2.1.5 Spare equipment strategies are typically designed to prevent long outages (possibility a year or more) of equipment with very long lead times. Any such strategy “could” result in these long outages depending upon the number of failures that may be postulated. This requirement is misleading and we thus recommend it be eliminated.</p> <p>R 2.2 We recommend the language for R 2.2 should be consistent with 2.1 for example - use "current or qualified past studies" instead of "the following annual current study."</p> <p>R 2.6.2 We recommend that the wording of this requirement remain unchanged.</p> <p>R 2.7.1 This portion of the requirement provides a list of “acceptable” Corrective Action Plans. It provides equal weight to infrastructure reinforcements and Special Protection Systems as means to mitigate violations resulting from single or multiple contingencies at both the EHV and HV levels. National Grid’s position is that a national standard should not endorse the use of Special Protection Systems as corrective actions to mitigate single contingency violations. Local Northeast Planning Criteria indicates that special protection systems (SPS) shall be used judiciously and may be used to provide protection for infrequent contingencies, or for temporary conditions that may exist such as project delays, unusual combinations of system demand and equipment outages or availability, or specific equipment maintenance outages. A SPS may also be applied to preserve system integrity in the event of severe facility outages and extreme contingencies. The decision to employ a SPS shall take into account the complexity of the scheme and the consequences of correct or incorrect operation as well as its benefits. We are further of the opinion that specific methods of correcting system performance deficiencies should not be specified in a National Standard. We thus recommend that the Corrective Action List be eliminated from this requirement as illustrated below. 2.7.1. List System deficiencies and the associated actions needed to achieve required System performance.</p> <p>R 2.7.2 We feel that this requirement and requirement R 2.1.4 adds ambiguity to the process as we have</p>

Organization	Yes/ No	Question 3 Comment
		<p>indicated above. We thus recommend that this requirement be eliminated.</p> <p>R 3.3.1 We feel that the last sentence of 3.3.1 should be removed. This is handled by PRC-023. Line ratings are addressed by PRC-023. PRC-023 requires coordination with the Reliability Coordinator. Remove “Tripping of Transmission elements where relay loadability limits are exceeded”</p> <p>Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall: 3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent: o Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.</p> <p>R 3.4.1 We would recommend the following addition as a clarification to the required information exchange: 3.4. Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information. 3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their respective Systems are included in the Contingency list.</p> <p>R 8.1 National Grid’s concern regarding this requirement stems from the apparent open ended time frame afforded report recipients in their review of the Planning Assessment. This has the potential to stall the review process. National Grid thus recommends that any recipient of the Planning Assessments be given a specific time period for their response as indicated in R 8.1 below. R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators, and adjacent Transmission Planners, within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. [Violation Risk Factor: LowMedium] [Time Horizon: Long-term Planning] 8.1. The recipient of the Planning Assessment results shall provides documented final comments on the results within 90 calendar days of receipt of the Planning Assessment. The respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.</p> <p>Table 1 Steady State & Stability Performance Planning Events (Page10). The event description for</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>Category P2 Event 1. along with the accompanying footnote 7 (Page 14) creates some confusion for multi-terminal lines. We recommend that Footnote 7 be eliminated and the event description be changed as follows: Category Initial Conditions Event P2 Normal System 1. Opening of a single load interrupting device at one terminal of a line without a fault.</p> <p>Table 1 (Planning Events and Extreme Events) Footnote 12 (Page 14).We are concerned that additional stakeholder process indicated in Footnote 12 has the potential to stall the Planning Assessment review process. We recommend that reference to this new process be eliminated from the Footnote.Our additional concerns with Footnote 12 are addressed in comments originally provided by ISO-NE. We agree with their following comments : The following language for Footnote 12 is proposed:”Planned or controlled interruption of electric supply to radial customers or some local Network customers, connected to or supplied by the Faulted element or by the affected area, may occur in certain areas without impacting the overall reliability of the interconnected transmission systems.”If Footnote 12 in Table 1 must be retained, the following language is proposed: “An objective of the planning process shall be to minimize the likelihood and magnitude of interruption of Demand, (excluding Interruptible Demand or Demand-Side Management), following Contingency events. However, it is recognized that Demand will be interrupted if it is directly served by the Elements removed from service as a result of the Contingency. Furthermore, in limited circumstances Demand may need to be interrupted to address BES performance requirements. When interruption of Demand is utilized within the planning process to address BES performance requirements, such interruption is limited to: a. Interruptible Demand or Demand-Side Managementb. Circumstances where the uses of Demand interruption not directly interrupted by the contingency are documentedc. Curtailment of firm transfers is allowed to meet BES performance requirements and meet applicable Facility Ratings, where it can be demonstrated it does not result in the interruption of any Demand (other than Interruptible Demand or Demand Side Management)”</p>
<p>Response: Requirement R1, Part 1.1.2 – The SDT and a majority of industry stakeholder support the 6-month period stated in the requirement. No change made.</p> <p>Requirement R1, Part 1.1 – Same comment as above. No change made.</p> <p>Requirement R2, Part 2.1.4 – Requirement R2, Parts 2.1.4 and 2.4.3 are not inconsistent with Requirement R2, Part 2.7.2. With the various requirements, the planners are required to conduct multiple sensitivities. Therefore, Requirement R2, Part 2.7.2 could be used when the results of these multiple sensitivities identify common concerns. No change made.</p> <p>Requirement R2, Part 2.1.5 is intended to analyze the removal of a single piece of long lead time equipment (one year or more) to the extent there is no existing</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>spare equipment strategy to provide a means of returning to service (in less than one year) a comparable replacement. If this condition exists, then the facility (single element) in question must be removed in the model to establish a new P0 system condition and studies must then be run for P0, P1, and P2 for the new system scenario. The spare equipment strategy must be reviewed for the entity's system exposure to catastrophic failures resulting in the long lead-time facility outages, however, only one facility must be removed at a time if the condition exists for multiple facilities. A Transmission Planner may have no spare equipment strategy if they are able to demonstrate they are not responsible for any facilities which they believe could place them in a "long lead-time" scenario. No change made.</p> <p>Requirement R2, Part 2.2 - The requirement for an annual current steady-state study in the Long-Term Transmission Planning Horizon is intentional to drive earlier identification of potential Transmission performance limitations and earlier development of Corrective Action Plans. The study results can be used as qualified studies as they advance to later years, including moving to the Near-Term Transmission Planning Horizon. No change made.</p> <p>Requirement R2, Part 2.6 – The changes made to this requirement in the last draft were essentially style changes and the most substantive change is the introduction of documentation required to support the technical rationale for determining whether or not material changes have occurred. This was a recommendation made by the Quality Review process and agreed to by the SDT. No change made.</p> <p>Requirement R2, R2.7.1 – The SDT respectfully disagrees that actions that could be part of a Corrective Action Plan (CAP) should be eliminated. In regard to the concern of allowing SPS within the CAP, this view is not shared across the continent-wide footprint and National Grid and its Regional Entity always have the ability to go above and beyond the requirements of a NERC standard if they believe such action is warranted. No change made.</p> <p>Requirement R2, Part 2.7.2 - Requirement R2, Parts 2.1.4 and 2.4.3 are not inconsistent with Requirement R2, Part 2.7.2. With the various requirements, the planners are required to conduct multiple sensitivities. Therefore, Requirement R2, Part 2.7.2 could be used when the results of these multiple sensitivities identify common concerns. No change made.</p> <p>Requirement R3, Part 3.3.1 – The SDT appreciates the concern raised; however, it believes the subsequent tripping of "Transmission elements where relay loadability limits are exceeded" is warranted. The TPL studies may earlier identify and flag relay setting concerns based on required Long-Term Transmission Planning Horizon studies. Within the TPL standard, such a concern would have a Corrective Action Plan that would address the issue which would also meet the expectations of PRC-023. The SDT sees this as a defense in depth approach. No change made.</p> <p>Requirement R3, Part 3.4.1 – The additional information suggested was not implemented as it did not add to reliability or clarify the issue beyond the present wording. No change made.</p> <p>Requirement R8, Part 8.1 – The SDT does not see a reliability related need for the suggestion and believes a response regarding a Planning Assessment is warranted no matter when raised by the reviewing party. No change made.</p>

Organization	Yes/ No	Question 3 Comment
		<p>Table 1, footnote 7 – The SDT added the footnote to further explain its intent for P2-1 and to ensure that the planner assess the voltage of a load bus that was on a radial line. The word “possibly” was used since having load on a radial is not always the outcome of opening one end of a line section. No change made.</p> <p>Table 1, Footnote 12 – The SDT believes the stakeholder process provides a level of transparency needed when an entity intends to utilize provisions offered by footnote 12 (and footnote 9). No change made.</p>
TVA TP&C		<p>TVA - has following comments:TVA is concerned about footnote 12 (known as footnote b in existing TPL standards). TVA believes that utilities should be given some freedom in dropping local load in response to N-1 events as long as overall BES reliability is not impacted. Otherwise significant capital improvements will be required that will have no overall reliability gain for the Bulk Electric System.</p> <p>In R4.1.1, TVA is concerned that no generating unit (including distributed generation) shall pull out of synchronism in a local area only (thus not impacting the overall reliability of the BES) for Planning Event P1, while the standard does allow generator runback/tripping for the same event. Thus the generating unit may be tripped by a special protection scheme - but may not be tripped by an out of step relay. TVA believes that out of step relaying should be allowed for this unit tripping as long as this does not affect the overall reliability of the BES.</p> <p>Table 1 contains both planning events and extreme events. Suggest labeling the planning events as Table 1 and the extreme events as Table 2 to help reduce confusion.</p> <p>VSL for R1 does not seem to address issues where data errors have been introduced into the latest model data. Also, R1 and its VSL may be interpreted to exclude the use of past models.</p> <p>The Implementation Plan should include a five-year delay in the effective date for short circuit studies (R2 parts 2.3 and 2.8) since these studies are a new TPL requirement and are not required in the current version 0 standards.</p>
		<p>Response: The SDT has taken care to ensure consistency in footnote 12 (and footnote 9) with the prior footnote ‘b’ revision supported by industry, approved by the NERC Board of Trustees, and submitted for regulatory approval. No change made.</p> <p>Requirement R4, Part 4.1.1 - The SDT respectfully disagrees with the commenter. For a P1 single Contingency event, the SDT believes, and a majority of industry stakeholders find it reasonable, that no Bulk Electric System (BES) generation unit be pulled out of synchronism due to the P1 event studied. If the “small” nearby unit is served below threshold kV and MW size limitations set by the Regional Entity to qualify as a BES unit, the unit would not be within scope of the standard. No change made.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
<p>Desire for Two Tables – This has been vetted within industry in prior comment/ballot periods. The majority of stakeholders support the current format. No change made.</p> <p>Requirement R1 VSL – The requirement indicates that supplied data may have to be supplemented as appropriate. The SDT believes that this covers correcting any data errors. The SDT sees no reason why the current language invalidates the use of past models as long as they meet the requirements. No change made.</p> <p>While short circuit study requirements may be new in the realm of mandatory enforceable standards, the SDT does not believe that they present a significant “raising of the bar” for industry. The SDT believes that prudent short circuit practices are effectively in place today to ensure safe operation of the equipment. Therefore, no extension in the Implementation Plan was made in regard to short circuit studies.</p>		
Independent Electricity System Operator		See our response to Q1.
<p>Response: See response to Q1.</p>		
NBSO		<p>Items that, if not addressed, will likely cause a negative vote from NBSO:</p> <p>NBSO believes that R1.1.2 is more appropriately addressed in the operational timeframe. Perhaps more appropriate alternatives could include:-only considering planned outages with durations of one year or more (in-line with typical planning timeframes), or -requiring that facilities with planned outages lasting over the complete duration of time period being studied be modeled out of service.</p> <p>R2.1.5 may significantly increase the demands of the planning assessments with little gain in reliability. Depending on interpretation, R2.1.5 could exponentially increase the work load of the annual planning assessment. NBSO interprets the intent of R2.1.5 to require that entities have, review and evaluate their spare equipment strategies. Perhaps the assessment of a spare equipment strategy would be more appropriately addressed in a separate standard.</p> <p>Further, categories P0, P1 and P2 do not reference footnote 9 in the Initial Condition column. NBSO is unclear if the last sentence of R2.1.5 allows for the curtailment of firm transmission service under the N-1 conditions before the application of category P0, P1 and P2 events. This last sentence states:”...with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.”</p> <p>Table 1, note b should be modified to allow for the loss of Firm Transmission Service. This addresses cases where Firm Transmission Service is lost in direct consequence to the event (e.g. loss of one DC pole, an</p>

Organization	Yes/ No	Question 3 Comment
		<p>interface comprised of a single line, a bus fault that clears multiple lines in an interface, etc...)</p> <p>Individual items that, if not addressed, may not cause NBSO to vote Negative, but in combination may result in a negative vote: The definitions of “near-term transmission planning horizon” and “year one” have been removed from the standard, yet they are still used in draft 7. Further, the definition of these terms is being filed as part of another project. NBSO is concerned with endorsing a standard based on terms whose definitions may change independently of this project.</p> <p>For R7, NBSO is concerned that one entity may be found noncompliant should another entity fail to meet their agreed upon responsibilities. For example, a PC may be relying on the results from a TP’s studies to complete its own planning assessment, but the TP did not meet their responsibilities. In this case, the PC should not be found non-compliant for an incomplete planning assessment due to the failure of the TP to meet their responsibilities. Contingencies on back to back HVDC facilities are not addressed in the standard.</p>
<p>Response: Requirement R1, Part 1.1.2 - The SDT disagrees with the view that outages of 6 months or more should only be reviewed in the operations timeframe. Such an outage could be for an upcoming construction project requiring certain facilities to be removed from service for long durations of time and those situations should be evaluated with sufficient lead time to determine any vulnerabilities and development of sufficient Corrective Action Plans as required. No change made.</p> <p>Requirement R2, Part 2.1.5 is intended to analyze the removal of a single piece of long lead time equipment (one year or more) to the extent there is no existing spare equipment strategy to provide a means of returning to service (in a less than one year) a comparable replacement. If this condition exists, then the facility (single element) in question must be removed in the model to establish a new P0 system condition and studies must then be run for P0, P1, and P2 for the new system scenario. The spare equipment strategy must be reviewed for the entity’s system exposure to catastrophic failures resulting in the long lead-time facility outages, however, only one facility must be removed at a time if the condition exists for multiple facilities. A Transmission Planner may have no spare equipment strategy if they are able to demonstrate they are not responsible for any facilities which they believe could place them in a “long lead-time” scenario. No change made.</p> <p>Requirement R2, Part 2.1.5 & Footnote 9 – Footnote 9 is not applicable to the Initial Condition (Pre-contingency) of P0, P1, and P2 even with a long lead-time device out of service. No change made.</p> <p>Table 1, footnote ‘b’ - The SDT believes the concern should be addressed by footnote 4, Conditional Firm Transmission Service. No change made.</p> <p>Removal of Definitions - Two previously proposed definitions that were part of this project were moved to another standard development project – Project 2010-10 titled “FAC Order 729”. The two definitions, “Near-Term Transmission Planning Horizon” and “Year One” were approved by the Board of Trustees on January 24, 2011.</p> <p>Requirement R7 – The SDT disagrees, having documented clear lines of responsibility should protect against the concern raised. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>Back to Back HVDC – The contingent loss of back to back HVDC facilities is included as a transformer. Footnote 5 states, in part, that “Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. Therefore, the SDT has not explicitly included back-to-back HVDC as a separate Contingency. No change made.</p>
<p>Xcel Energy</p>		<p>Effective Date: The effective date section seems to imply that Non-Consequential Load Loss will not be permitted after the 84 month implementation period. We do not believe that was the drafting team’s intent and request that it be modified.</p> <p>Footnote # 12 in Table 1, in particular, seems to support our assumption that the team did not intend to disallow it. For reference, the footnote states:”12. An objective of the planning process should be to minimize the likelihood and magnitude of Non-Consequential Load Loss following Contingency events. However, in limited circumstances Non-Consequential Load Loss may be needed to address BES performance requirements. When Non-Consequential Load Loss is utilized within the planning process to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss is documented, including alternatives evaluated; and where the utilization of Non-Consequential Load Loss is subject to review in an open and transparent stakeholder process that includes addressing stakeholder comments.” However, if it was the drafting team’s intent to not allow Non-consequential Load Loss after the 84 month implementation period, we disagree and ask the team to reconsider. Particularly for rural areas, in some cases, this will be the only action possible.</p> <p>R2.1.4: a) We would like to see clarification on the term “sensitivity analysis”. Is this in reference to seasonal models and differences in fuel availability? We would like more detail on how this is to be done so that it won’t be left up to interpretation.</p> <p>b) We would like the drafting team to consider stratification of the tasks needed to perform a Planning Assessment. In our opinion, having both the TP and PC do exactly the same study produces tremendous and unnecessary duplication. Without stratification, the TPL-001 standard will continue to perpetuate the same paradigm used in the existing TPL-001 through TPL-004 standards. The NERC Functional Model makes a clear distinction between PC and TP functions/responsibilities. It is not clear why that distinction is not leveraged in the new TPL-001 standard. This will be particularly troublesome in areas where an ISO or RTO is the Planning Coordinator. In order for the RTO/ISO, as the PC, to be able to do their Planning Assessment, the Transmission Planners would have to provide a lot of detailed input data. So, in effect, both the PC and TP would be performing their assessment from the same data. It would make more sense if the RTO (as the PC) performed the required studies on the 500-345 kV network and the TP performed the required studies on everything below 230 KV.</p>

Organization	Yes/ No	Question 3 Comment
		<p>We also recommend the allowance for utilization of a regional assessment, instead of performing your own, due to individual entity resource constraints.</p> <p>R2.4.1: We would like to see better clarity on what an Aggregate system load model is and how granular it should be. If the intent is for the model to contain a very detailed representation of the load system, then it may take a longer time to implement.</p> <p>R3.4.1: a) This type of coordination could be difficult due to other adjacent entities on different schedules and some may not have the amount of detail to incorporate into another's processes. We know this is generally covered in coordination of real time operations and wonder if it is appropriate to require this type of coordination in the long term process. Is there already an operational standard that covers this? Would it be better to address this in the operational standards? We would like the roles of the coordinators vs. the planners to be clarified in order to ensure that no work is being duplicated.</p> <p>b) PC's between regions, such as RTOs, are already coordinating for long term studies. In these cases, we feel the PC should alone be responsible for the requirements, rather than also the TPs.</p> <p>c) Can we get a clear definition of what apparent impedance swings means? We interpret it as rotor angle stability.</p> <p>R4.3.1: We would like to see that the detailed data is incorporated back into the NERC modeling processes and create a more detailed model with better accuracy.</p> <p>R8: We do not agree with the requirement to provide the assessment to every adjacent PC and TP because we fail to see the reliability benefit in doing so. However, we do agree that the PC and TP should be required to provide the assessment to any of these entities, if requested. Additionally, for entities that make such requests, we would like to have 90 days instead of 30 to respond. In many cases a non-disclosure agreement will have to be executed due to CEII classification of some information, and this can take several months.</p>
<p>Response: Effective Date - The SDT believes the Effective Date section is sufficiently clear. The use of Non-Consequential Load Loss while discouraged by the standard is permitted when justified and presented in a transparent manner to other stakeholders (footnote 12). No change made.</p> <p>Sensitivity Analysis – This analysis should be viewed as a modified study of the Peak or off-peak studies required in Requirement R2, Parts 2.1.1 and 2.1.2. The SDT believes the examples provided in the bulleted list of Requirement R2, Part 2.1.4 are sufficiently clear as examples of what could be modified to create the sensitivity model. No change made.</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>Delineation of tasks between Transmission Planner and Planning Coordinator – The issue raised is addressed by Requirement R7. No change made.</p> <p>Regional Assessments – The standard does not prohibit the use of valid studies performed by 3rd parties for use in the assessment results. No change made.</p> <p>Requirement R2, Part 2.4.1 - The “aggregate” dynamic Load model may include high-level assumptions on Load profiles for industrial, commercial, and residential Loads that are applied generically across the planning area study based on the planner’s engineering judgment and system knowledge. The model is not required to be “bus” specific. No change made.</p> <p>Requirement R3, Part 3.4.1 - The SDT envisions that knowledge of the applicable Contingencies on neighboring systems would develop over time and be discovered with the results being distributed in Requirement R8. The SDT believes that this is an important improvement to the planning timeframe analysis and that system information learned in the operations environment should most certainly be considered to the extent it improves the robustness of the planning assessment. No change made.</p> <p>Planning Coordinator responsibility – NERC’s Functional Model clearly places Transmission planning responsibility both on the Transmission Planner and Planning Coordinator. Requirement R7 should help alleviate any overlap concerns in responsibility. No change made.</p> <p>Apparent Impedance Swings - The “apparent impedance swing” is the trajectory of changes in the apparent impedance seen by a distance relay for various system and Fault conditions. In the case contemplated in Requirement R4, Part 4.1.2, it is the trajectory seen by the distance relay for the initial Fault and the subsequent generator(s) pulling out of synchronism. If that trajectory were to come within the tripping characteristic of the relay for a sufficient length of time, the relay would cause its associated line to trip. No change made.</p> <p>NERC Modeling Process – The standard does not govern NERC actions as they are not a registered entity. To the extent NERC pulls information from a model building process such as MMWG (ERAG) then the models used by NERC will likely contain the information desired. No change made.</p> <p>Requirement R8 – The SDT and a majority of industry support Requirement R8. No change made.</p>
ISO New England Inc.		<p>We feel previous comments have largely been ignored by the Standards Drafting Team leading to a lack of support for the standard. Overall the standard should be more precise in its language. The following comments are provided for serious consideration with respect to revisions:Comments: From Section A.3 - the introduction please strike the word “probable” as shown below Purpose: Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies This is deterministic contingency testing and this word introduces probability into the standard where it does not belong.</p> <p>For R1.1 Part 1.1.2. With respect to known outages, there needs to be greater flexibility in the standards (e.g. more tolerance to non-consequential load shedding or limitations to the contingencies that need to be</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>considered (e.g. P0, P1, & P2)). Regional allowances for load shedding under this condition should be acceptable. Duration of known outages should be increased from six months to one year.</p> <p>For R1.1 Part 1.1.6 Delete "required for Load". Resources may also be used for export to other areas, not just internal load.</p> <p>REMOVE INTERCHANGE from 1.1.5 - Definition of Interchange - The inclusion of Interchange requires designing for non-Firm service. In the NERC Glossary of Terms Used the term Interchange is defined as "Energy transfers that cross Balancing Authority boundaries." It is meant to refer to energy transaction other than firm Transmission Service. While rigorous planning studies have been conducted to permit the uninterrupted implementation of firm Transmission Service without jeopardizing the reliable operation of the Interconnected System, other types of energy transaction only take place whenever system conditions permit them. They are usually of very short duration relative to planning assessment periods (usually spanning for a few hours to a few days) and are deemed highly interruptible and subject to reliability issues that may arise during operation of the system. In other words, the term Interchange refers to economic transactions that are permitted when the system is secure and there are reasonable reliability margins to effect dispatch changes to lower operating costs. As such, Interchange should not be reflected in system representation meant to assess system reliability under TPL-001.</p> <p>Part 2.1.4, requires an entity to vary one or more conditions to demonstrate a change in performance. If the cases were initially stressed, this may force an entity to simulate conditions with less severe stresses. At this point, there is limited or no value to this additional workload. Having a requirement to test at least one sensitivity as a blanket requirement may not be informative by itself and is more unclear since sensitivities are being required on an undefined base set of conditions. Additionally, our concern involves wording under 2.1.4 and 2.4.3 that sensitivities are required varying one or more conditions. Subsequently, in requirement 2.7.2 corrective action plans need to be developed to resolve performance deficiencies "only" if identified in multiple conditions or require a rationalization why no corrective action plan is necessary. Multiple condition sensitivities under 2.1.4 and 2.4.3 are necessary to satisfy requirement 2.7.2. Requirement 2.7.2 adds ambiguity and should be removed or revised as follows: 2.7.2. Corrective Action Plans are not required for performance deficiencies identified in a sensitivity analysis.</p> <p>We agree with R2.1 however with respect to R2.2 Language should be consistent with 2.1 for example - use "current or qualified past studies" instead of "the following annual current study."</p> <p>For 2.7.1 - We don't believe this list provides value nor should it be included in the standard.</p> <p>Section 3.3 - We feel that the last sentence of 3.3.1 should be removed. This is handled by PRC-023. Line</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>ratings are addressed by PRC-023. PRC-023 requires coordination with the Reliability Coordinator. Remove “Tripping of Transmission elements where relay loadability limits are exceeded.”</p> <p>In Table 1 - The fault descriptions must be clear. They must use “3-phase”, “single-phase-to ground”, or “2-phases-to ground” in the descriptions of a fault rather than SLG (a line is not a phase in electrical terms-- single line to ground is not precise enough).</p> <p>In Table 1 - Where two elements are affected by a fault it must be clear whether the requirement is for a single-phase-to ground fault, or a 2-phase-to ground fault. They are different faults that will have different dynamic responses.</p> <p>For Table 1- add a footnote for the term generator to address the treatment of Combined Cycle Generators - “In addition to evaluating the loss of a single generator, the loss of all interrelated generators shall also be considered as a single contingency.” Operating experience has shown that trips of the entire CC facility often occur even on facilities that claim the combined cycle generators are independent.</p> <p>Where a category involves an initial condition representing the loss of a facility followed by an event representing the loss of a facility such as P3, the standard must be clear as to the amount of time assumed between faults. An assumption may be 30 minutes, but the standard must not leave this unsaid. This clarity must be provided in the Table 1</p> <p>Notes. In addition, the standard must be clear on the allowable re-adjustments between contingencies such as P3, or better, must be clearly limit the permissible re-adjustments. For example, it is not realistic to assume an unlimited amount of re-dispatch between faults-e.g. the allowable re-adjustment should be limited to actions that can be effectively implemented in less than 30 minutes, such as a, b, c, d,, and the amount of generation re-dispatch must not exceed the amount of future planned contingency reserve, or similar language. This clarity must be derivable from the Table 1 Notes.</p>
<p>Response: A.3 Purpose Statement – While admittedly “probable” is somewhat in the eye of the beholder the intent is that Bulk Electric System (BES) should operate reliably for the more “probable” or “credible” Contingencies, i.e., Planning Events (Table 1), and that the BES reliability performance expectation is lower for the less “probable” extreme events. The SDT does not see this statement as defining the standard as probabilistic Contingency planning and agrees that the standard is deterministic planning. No change made.</p> <p>Requirement R2, Part 1.1.2 – The SDT disagrees that the duration of known outages should be increased from 6 months to one year. The intent is to ensure review of an upcoming construction project requiring certain facilities to be removed from service for long durations of time and those situations should be evaluated with sufficient lead time to determine any vulnerabilities and development of sufficient Corrective Action Plans (CAP) as required. The SDT believes it is</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>appropriate to study all planning events for the projected system and not limit it to just P0, P1. or P2. Load shedding could be part of a “temporary” CAP when justified by the use of footnote 12. No change made.</p> <p>Requirement R1, Part 1.1.6 - The SDT does not believe the phrase “required for Load” is confusing. Without the statement, in theory, one could have a model with lots of supply resources but none which are dispatched to serve the Load. The term Load does not depict whether it is located internal or external to the Transmission system footprint. No change made.</p> <p>Requirement R1, Part 1.1.5 – Both firm and non-firm transfers of power should be modeled to the extent they are “known commitments” in the Planning Horizon. The short duration transactions described would likely not be known and therefore should not be included in a planning model. No change made.</p> <p>Requirement R2, Part 2.1.4 – the commenter has missed the key phrase “... by a sufficient amount to stress the System ...”. So, by definition of the requirement the sensitivity analysis is not intended to lower the overall stress of the system being analyzed. Additionally, Requirement R2, Parts 2.1.4 and 2.4.3 are not inconsistent with Requirement R2, Part 2.7.2. With the various requirements, the planners are required to conduct multiple sensitivities. Therefore, Requirement R2, Part 2.7.2 could be used when the results of these multiple sensitivities identify common concerns. No change made.</p> <p>Requirement R2, Part 2.2 - The requirement for an annual current steady-state study in the Long-Term Transmission Planning Horizon is intentional to drive earlier identification of potential transmission performance limitations and earlier development of Corrective Action Plans (CAPs). The study results can be used as qualified studies as they advance to later years, including moving to the Near-Term Transmission Planning Horizon. No change made.</p> <p>Requirement R2, R2.7.1 – The SDT respectfully disagrees that example actions that could be part of a Corrective Action Plan (CAP) should be eliminated. If an entity takes issue with the use of one of the stated items as part of a CAP, they are always free to go above and beyond the requirements of a NERC standard if they believe such action is warranted. No change made.</p> <p>Requirement R3, Part 3.3.1 – The SDT appreciates the concern raised; however, it believes the subsequent tripping of “Transmission elements where relay loadability limits are exceeded” is warranted. The TPL studies may earlier identify and flag relay setting concerns based on required Long-Term Transmission Planning Horizon studies. Within the TPL standard, such a concern would have a CAP that would address the issue which would also meet the expectations of PRC-023. The SDT sees this as a defense in depth approach. No change made.</p> <p>Fault Types – Only single line to ground (SLG) and three-phase (3PH) fault types are covered by the standard. See Table 1, footnote 2 for further information on fault types and standard expectations. No change made.</p> <p>Combined Cycle Plants – If the planner believes it is appropriate to model the tripping of the combined cycle generation as a set then they should do so. Recall, in planning assessments, you are analyzing Contingency events based on electrical Faults and the SDT reminds the commenter that adherence to introductory Table 1 note “c” is required. Additionally, to the extent the combined cycle units deliver their power via a common GSU transformer the loss of the GSU should also address the concern. No change made.</p> <p>System Adjustments – The timing between events which are not common mode events (P3, P6) is not defined by the standard. Engineering judgment should</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>prevail and if the planner believes a susceptibility to an N-2 event of quick duration places their system at risk then the use of automatic controls should be considered. The only qualifier on System adjustments is that Facility Ratings must be adhered to during the adjustment. So, if you are adhering to a 30-minute Emergency Rating, but are exceeding a 24-hour Emergency Rating then the adjustment must be completed within the time limitation of the rating. No change made.</p>
Northeast Utilities		<p>The following previous comments that were filed by NU were not addressed by the SDT in the current draft. For NU to support the standard these comments should be addressed or reasons should be provided why they have not been addressed. Repeated below are NU’s comments that were filed for the previous draft.</p> <p>Requirement R1, Part 1.1.2 NU requests that the six month duration stated by Requirement R1, Part 1.1.2 should be modified to one year duration to eliminate outages that occur within the “operational planning timeframe”.</p> <p>Requirement R1, Part 1.1.6The phrase "required for Load" should be deleted as this confuses the issue.Requirement R2, Part 2.2The language of Requirement R2</p> <p>Part 2.2 seems to suggest that current annual studies are always required for the long-term steady state assessment. This may have been an oversight, for consistency Requirement R2 Part 2.2 should be modified to similarly read as Requirement R2, Part 2.1.</p> <p>Requirement R2, Parts 2.1.4 & 2.4.31) The standard is referring to requirements for sensitivity and other issues without a reference to base assumptions. The standard must describe base assumptions. To define a sensitivity condition, NERC must define base assumptions.</p> <p>2) Requirement R2, Part 2.1.4 and Part 2.4.3 should clarify what is meant by multiple sensitivity studies and one sensitivity study. Will varying only one measurable quantity several times in multiple simulations constitute multiple sensitivity studies or one sensitivity study?</p> <p>Requirement R3, Part 3.3.1NU feels that the last sentence of Requirement R3, Part 3.3.1 should be removed since this is handled by PRC-023. Line ratings are addressed by PRC-023 which requires coordination with the Reliability Coordinator. NU suggests the removal of the following sentence: “Tripping of Transmission elements where relay loadability limits are exceeded.”</p>
<p>Response: Requirement R1, Part 1.1.2 - The SDT disagrees with the view that outages of 6 months or more should only be reviewed in the operations timeframe. Such an outage could be for an upcoming construction project requiring certain Facilities to be removed from service for a long durations of time and those situations should be evaluated with sufficient lead time to determine any vulnerabilities and development of sufficient Corrective Action Plans as required. The</p>		

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>review of known and planned construction items should not be delayed until the operations timeframe. No change made.</p> <p>Requirement R1, Part 1.1.6 - The SDT does not believe the phrase “required for Load” is confusing. Without the statement, in theory, one could have a model with lots of supply resources but none which are dispatched to serve the load. No change made.</p> <p>Requirement R2, Part 2.2 - The requirement for an annual current steady-state study in the Long-term Transmission Planning Horizon is intentional to drive earlier identification of potential Transmission performance limitations and earlier development of Corrective Action Plans (CAP). The study results can be used as qualified studies as they advance to later years, including moving to the Near-Term Transmission Planning Horizon. No change made.</p> <p>Requirement R2, Parts 2.1.4 & 2.4.3 – The “base case” assumption is described in Requirement R1 by the fact that the P0 model “shall represent the projected System conditions” for the study period. That essentially establishes the “base case” condition. The sensitivity analysis in Requirement R2, Part 2.1.4 is intended to address some potential “what if” conditions that the planner should consider as an alternate base P0 condition. The SDT believes Requirement R2, Part 2.1.4 provides sufficient detail and clarity of the intended purpose of a sensitivity study and defers to engineering judgment in how the alternate base (sensitivity) model is established. Varying one variable multiple times would cover multiple sensitivities. For example, one may vary the Load modeled. If the base condition is a 50/50 forecast model, one sensitivity may be an 80/20 forecast, while yet another is a 90/10 forecast model. No change made.</p> <p>Requirement R3, Part 3.3.1 – The SDT appreciates the concern raised; however, it believes the subsequent tripping of “Transmission elements where relay loadability limits are exceeded” is warranted. The TPL studies may earlier identify and flag relay setting concerns based on required Long-Term Transmission Planning Horizon studies. Within the TPL standard, such a concern would have a CAP that would address the issue which would also meet the expectations of PRC-023. The SDT sees this as a defense in depth approach. No change made.</p>
MISO		<p>Overall, we remain concerned that the revisions to the TPL standard are not on balance an improvement to the original. The document is not well organized topically, making it more difficult to navigate and understand. If the primary improvements sought in requirements for reliability planning were to increase system performance levels (no loss of firm demand) for certain multiple contingency events, and to ensure more stressed system sensitivities are analyzed, this can be accomplished in a much simpler revision. We do not believe that this standard as written improves the clarity of what is required, and therefore provides an opportunity for greater disputes between compliance monitors and applicable entities, and this is not a positive outcome. We also believe that the standard is too prescriptive as to what critical system conditions must be modeled, as these conditions vary considerably from system to system and within large systems.</p> <p>Table 1-Steady State and Stability Performance Planning Events, Category P5, now includes “non-redundant” relay in the Event column. What is meant by non-redundant relay? It is unclear if the SDT’s intent is to provide distinction between a back-up relay and a redundant relay. We recommend that the SDT provide a definition for the term “non-redundant”.</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
Consumers Energy	Ballot Comment	We agree with comments submitted by MISO
<p>Response: The SDT and others in industry hold a different opinion in regards to the standard. The SDT refers you to the comments provided by Transmission Strategies, LLC which well articulates what it believe is the opinion of many in industry evidenced by the 74% approval during the last ballot. Transmission Strategies, LLC states “The SDT, Observers, and the Industry as a whole have put a tremendous amount of thought and work into the development of this latest draft. While nobody should claim that this latest version is perfect, it is far clearer, more in tune with current industry needs, and much improved compared to the existing approved Standards that it will replace”. No change made.</p> <p>Redundant Relay – Redundant means duplicate capability resulting in the same outcome. The redundant relay is not the same as a back-up relaying capability which may result in more Facilities being removed for failure of the primary/redundant relay to operate as designed. The SDT believes this concept is widely understood by most in industry and does not see the need for a NERC Glossary Definition. No change made.</p>		
New York Independent System Operator		Requirement R2.4.1The NYISO, along with many other systems, has not determined a need to model dynamic loads, and therefore has not benchmarked any such models. The NYISO recommends that prior to the implementation of this requirement a modeling standard should exist that is specific to dynamic loads, including as assessment for the need for dynamic load models.
<p>Response: Requirement 2, Part 2.4.1 – One focus of the dynamic Load model requirement in Requirement R2, Part 2.4.1 is “considering the behavior of induction motor load”. The areas of concern for induction motor load are the Peak load periods since Fault Induced Delayed Voltage Recovery (FIDVR) is primarily a concern at a high load levels with a high penetration of induction motor loads. The SDT has spelled out this requirement in the Peak Load studies but did not include the explicit requirement, with focus on induction motor load, for the other load periods. Even though the standard doesn’t have the explicit requirement for other load levels, Requirement R1 includes the statement “shall represent projected System conditions”, so the planner cannot ignore the dynamic behavior of the load for those other load periods. No change made.</p>		
Ameren		<p>With respect to Requirement R8, will posting the assessment to a secure web site meet the intent of the requirement? What are the Planning Assessment results identified in R8, and how are they different from the Planning Assessment?</p> <p>It appears that the language for R8 is inconsistent with the VSL for R8. The revised language for the VSL for R8 has removed the word “results”.</p> <p>For Measurements M3 and M4, there is still some question as to what is to be provided as sufficient evidence of a study. It is not clear whether the study results would be sufficient, or whether the entire powerflow,</p>

Consideration of Comments on Assess Transmission Future Needs and Develop Transmission Plans — Project 2006-02

Organization	Yes/ No	Question 3 Comment
		<p>stability, or short circuit effort needs to be documented in a formal study report. For example, it is not clear whether contingency lists used in performing the study work would need to be retained as part of the documentation.</p> <p>The items listed as 4.1.1 through 4.1.3 are not requirements but are performance criteria and should be included in the Table 1 only, consistent with the other performance criteria.</p> <p>Overall, we believe that this standard does not improve the clarity of what is required, and would give additional occasions for disputes between compliance monitors and various registered entities. The standard as written is too prescriptive with regard to critical system conditions which are to be modeled. Such conditions would vary considerably for different systems across the continent.</p>
<p>Response: Requirement R8 – Posting results to a secure website with adequate communication that the results are available for review would suffice for Requirement R8. The “Planning Assessment” and “Planning Assessment results” are one and the same. No change made.</p> <p>Measures M3 and M4 – The evidence could be a combination of summary documented results, the power flow case itself, the Contingency lists, output files showing evidence of the Contingency analysis being performed, etc. No change made.</p> <p>The SDT believes the items in Requirement R4, Parts 4.1.1 through 4.1.3 are properly located. The standard is the sum of the parts – requirements and the Table and the location of the highlighted items is not critical to the desired outcome. No change made.</p> <p>Clarity of the standard - The SDT and others in industry hold a different opinion in regard to the standard. The SDT refers you to the comments provided by Transmission Strategies, LLC which well articulates what it believes is the opinion of many in industry evidenced by the 74% approval during the last ballot. Transmission Strategies, LLC states “The SDT, Observers, and the Industry as a whole have put a tremendous amount of thought and work into the development of this latest draft. While nobody should claim that this latest version is perfect, it is far clearer, more in tune with current industry needs, and much improved compared to the existing approved Standards that it will replace”. No change made.</p>

Mapping Document

Project 2006-02 Assess Transmission Future Needs

Mapping document showing the translation of TPL-001-2 – System Performance Under Normal (No Contingency) Conditions (Category A); TPL-002—1b – System Performance Following Loss of a Single Bulk Electric System (BES) Element (Category B); TPL-003-1a – System Performance Following Loss of Two or More Bulk Electric System Elements (Category C); TPL-004-1 – System Performance Following Extreme Events Resulting in the Loss of Two or More Bulk Electric System Elements (Category D); TPL-005-0 – Regional and Interregional Self-Assessment Reliability Reports; and TPL-006-0.1 – Data From the Regional Reliability Organization Needed to Assess Reliability.

Standard TPL-001-1 – System Performance Under Normal (No Contingency) Conditions (Category A)		
Requirement in Approved Standard	Translation to New Standard or Other Action	Description (as needed)
R1	TPL-001-2, R1 & R2 TPL-001-2, Table 1 – P0	Requirement R1 sets P0 in Table 1 as the normal system condition.
R1.1	TPL-001-2, R2.1 TPL-001-2, R2.2	Requirement R2.1 is for near-term and Requirement R2.2 is for long-term
R1.2	TPL-001-2, R2.1 TPL-001-2, R2.2	Requirement R2.1 is for near-term and Requirement R2.2 is for long-term
R1.3	TPL-001-2, R2.3 TPL-001-2, R2.4	Requirement R2.3 is for near-term and Requirement R2.4 is for long-term
R1.3.1	TPL-001-2, R2.1.1 TPL-001-2, R2.1.2 TPL-001-2, R2.2.1 TPL-001-2, R1	Requirements R2.1.1 & 2.1.1 are for near-term and Requirement R2.2.1 is for long-term. These new requirements are more stringent than the existing as they require annual assessments regardless of whether the system has changed or not. Requirement R1 is for System models.
R1.3.2	TPL-001-2, R2.1.1 & R2.1.2 TPL-001-2, R2.2.1	Requirements R2.1.1 & R2.1.2 are for near-term and Requirement R2.2 is for long-term.
R1.3.3	TPL-001-2, R2.2.1	This requirement is more stringent than the existing requirement in that it requires a long-term assessment regardless of system conditions.
R1.3.4	TPL-001-2, R1	Normal (pre-contingency) operating procedures, if required, are a part of a Corrective Action Plan and therefore, are required to be included in the System model.

R1.3.5	TPL-001-2, R1.1.5	
R1.3.6	TPL-001-2, R1 & R2.1.1 TPL-001-2, R1 & R2.1.2 TPL-001-2, R2.1.4	Requirements R1, R2.1.1, & R2.1.2 set up the base requirements and Requirement 2.1.4 requires sensitivity analysis to demonstrate the impact of changes to the basic assumptions used in the model.
R1.3.7	TPL-001-2, R1 TPL-001-2, Table 1	Requirement R1 sets P0 in Table 1 as the normal system condition.
R1.3.8	TPL-001-2, R1.1.1 TPL-001-2, R1.1.3	
R1.3.9	TPL-001-2, R1.1.4	Requirement R1.1.4 requires that Reactive Power forecasts are utilized and that performance is met for same.
R1.4	TPL-001-2, R1 & R1.1.3	
R2	N/A	Introductory sentence
R2.1	TPL-001-2, R2.7	
R2.1.1	TPL-001-2, R2.7	Requirement 2.7 requires the development of a Corrective Action Plan which includes a schedule for implementation.
R2.1.2	TPL-001-2, R2.7	Requirement 2.7 requires the development of a Corrective Action Plan which includes a schedule for implementation.
R2.1.3	TPL-001-2, R2.7	Requirement 2.7 requires the development of a Corrective Action Plan which includes a schedule for implementation.
R2.2	TPL-001-2, R1	
R3	TPL-001-2, R2 TPL-001-2, R8	Requirement R2 requires the documentation of the assumptions and summarized results. The revised Requirement R8 is more stringent than the existing requirement in that it includes other Planning Coordinators and Transmission Planners as well as functional entities having a reliability-based need.

Standard TPL-002—1b – System Performance Following Loss of a Single Bulk Electric System (BES) Element (Category B)

Requirement in Approved	Translation to	Description (as needed)
-------------------------	----------------	-------------------------

Standard	New Standard or Other Action	
R1	TPL-001-2, R1, R2, R3.1, & R4.1 TPL-001-2, Table 1 – P1 & P2-1	
R1.1.	TPL-001-2, R2.1 TPL-001-2, R2.2	Requirement R2.1 is for near-term and Requirement R2.2 is for long-term.
R1.2	TPL-001-2, R2.1 & 2.4 TPL-001-2, R2.2 & 2.5	Requirements R2.1 & R2.4 are for near-term and Requirements R2.2 & R2.5 are for long-term.
R1.3.	TPL-001-2, R3 TPL-001-2, R4	Requirement R3 is for steady-state. Requirement R4 is for stability.
R1.3.1	TPL-001-2, R3.4 TPL-001-2, R4.4	Requirement R3.4 is for steady-state and Requirement R4.4 is for stability.
R1.3.2	TPL-001-2, R2.1 & R2.4 TPL-001-2, R2.2 & R2.5 TPL-001-2, R1	Requirements R2.1 & R2.4 are for near-term. Requirement R2.2 is for long-term. Requirement R1 is for System models.
R1.3.3	TPL-001-2, R2.1.1, R2.1.2, R2.4.1, & R2.4.2 TPL-001-2, R2.2.1 & R2.5	Requirements R2.1.1, R2.1.2, R2.4.1 & R2.4.2 are for near-term and Requirements R2.2.1 & R2.5 are for long-term. These new requirements are more stringent than the existing as they require annual assessments regardless of whether the system has changed or not.
R1.3.4	TPL-001-2, R2.2.1 TPL-001-2, R2.5	These requirements are more stringent than the existing requirement in that it requires a long-term assessment regardless of system conditions.
R1.3.5	TPL-001-2, R1.1.5	
R1.3.6	TPL-001-2, R1, R2.1.1 & R2.4.1 TPL-001-2, R1, R2.1.2 & R2.4.2 TPL-001-2, R2.1.4	Requirements R1, R2.1.1, R2.1.2, R2.4.1, & R2.4.2 set up the base requirements and Requirement 2.1.4 requires sensitivity analysis to demonstrate the impact of changes to the basic assumptions used in the model.

R1.3.7	TPL-001-2, R3.1 & R4.1 TPL-001-2, Table 1 – P1 & P2-1	
R1.3.8	TPL-001-2, R1.1.1 TPL-001-2, R1.1.3	
R1.3.9	TPL-001-2, R1.1.4	Requirement R1.1.4 requires that Reactive Power forecasts are utilized and that performance is met for same.

Project 2006-02 Assess Transmission Future Needs and Develop Transmission Plans

Related Files

Status:

The NERC Board of Trustees adopted the TPL-001-2 standard on August 4, 2011. The Implementation Plan for TPL-001-2 will retire TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1 at midnight the day before TPL-001-2 becomes effective as they are replaced in their entirety by TPL-001-2 (subject to regulatory approval). The Implementation Plan also calls for retiring TPL-005-0 and TPL-006-0.1 at that time (subject to regulatory approval) because the Requirements are either covered by the revised TPL-001-2 or by Section 800 of NERC’s Rules of Procedure.

Purpose/Industry Need:

The revisions to the following standards would improve technical clarity and address concerns identified by stakeholders and FERC:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

The final SAR is to establish a standard for assessing and planning the transmission systems in North America. The transmission system must be assessed and planned to ensure that it performs its intended functions in providing reliable delivery of power for the future needs of customers.

Standard Authorization Request (SAR) Form

Title of Proposed Standard:	Assess Transmission Future Needs and Develop Transmission Plans
Request Date:	March 6, 2002
Authorized for Posting:	March 20, 2002
SAR ID# :	TRNS_NDS_&_PLNS_01_01

SAR Requestor Information		SAR Type (Put an 'x' in front of one of these selections)	
Name:	Jim Byrd	X	New Standard
Primary Contact:	Jim Byrd		Revision to existing Standard
Telephone:	214-743-6870		Withdrawal of existing Standard
Fax:	972-263-6710		
e-mail:	jbyrd@txu.com		Emergency Action

Purpose/Industry Need (Provide one or two sentences)

To establish a standard for assessing and planning the transmission systems in North America.
 The transmission system must be assessed and planned to ensure that it performs its intended functions in providing reliable delivery of power for the future needs of customers.

Brief Description (A few sentences or a paragraph)

Requirements shall be established for assessing transmission system performance under a variety of system conditions including system normal conditions, abnormal conditions, and extreme system conditions. Requirements shall be established for a plan, including a definition of the planning horizon, to address these conditions to ensure that the interconnected transmission systems perform their intended functions and to prevent severe adverse effects such as uncontrolled or cascading interruption of network operation. The plan may utilize operating, construction, market solutions or other components to address these conditions.

SAR: Assess Transmission Future Needs and Develop Transmission Plans

Reliability Functions

The Standard will Apply to the Following Functions (Put an 'X' in front of each one that applies)		
X	Reliability Authority	Ensures the reliability of the bulk transmission system within its Security Authority Area. This is the highest reliability authority.
	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within its metered boundary and supports system frequency in real time
	Interchange Authority	Authorizes valid and balanced Interchange Schedules
X	Planning Authority	Plans the bulk electric system
	Transmission Service Provider	Provides transmission services to qualified market participants under applicable transmission service agreements
X	Transmission Owner	Owns transmission facilities
	Transmission Operator	Operates and maintains the transmission facilities, and executes switching orders
	Distribution Provider	Provides and operates the "wires" between the transmission system and the customer
	Generator	Owns and operates generation unit(s) or runs a market for generation products that performs the functions of supplying energy and Interconnected Operations Services
	Purchasing-Selling Entity	The function of purchasing or selling energy, capacity and all necessary Interconnected Operations Services as required.
	Load-Serving Entity	Secures energy and transmission (and related generation services) to serve the end user

SAR: Assess Transmission Future Needs and Develop Transmission Plans

Reliability and Market Interface Principles

Applicable Reliability Principles (Put an 'x' in front of all that apply)	
X	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions.
	2. The frequency of interconnected bulk electric systems shall be controlled within defined limits through the balancing of electric supply and demand
X	3. Information necessary for planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably
	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented
	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems
X	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified and have the responsibility and authority to implement actions
X	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis
<p>Does the proposed Standard comply with all of the following Market Interface Principles?</p> <p style="text-align: right;">YES</p> <p><i>(Enter 'yes' or 'no')</i></p>	
	1. Interconnected The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy
	2. An Organization Standard shall not give any market participant an unfair competitive advantage
	3. An Organization Standard shall neither mandate nor prohibit any specific market structure
	4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard
	5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards

Assess Transmission Future Needs and Develop Transmission Plans

E-mail	phil.park@powerex.com
<p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed:</p> <p>I have a general comment to preface my comments on the individual SARs. To me, what we are calling a "core reliability requirements" are simply technical specifications for things we believe the industry cannot adequately address through commercial negotiations between individual players or things too small to bother with by one on one negotiations. Core reliability requirements do not include business practices. These technical specification should ensure that they do not prohibit worthwhile commercial negotiations. With this definition, all core reliability requirements have commercial elements. I can accept this and this should not inhibit us from setting a technical specification (core reliability requirement) where one makes sense. However, we must avoid setting one whenever we can, simply because we can. This latter approach will inhibit valuable commercial activity. If the reliability standards become so encompassing that they threaten commercial activity, we will simply end up focusing on including exemptions, waivers, and differences such that the standard has limited applicability.</p> <p>In many cases in my comments below I have not indicated whether or not the proposed standard is required. This can only be determined after we have rationalized the details of each of the SARs. The answer to this question should be an outcome of the process, not an input to it.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input type="checkbox"/> The scope of the SAR should be reduced to eliminate: The description should be revised as follows: "Requirements shall be established to ensure that interconnected transmission systems are planned such that they can reliably perform their intended functions over a wide range of system conditions." The phase "while continuing to operate reliably within equipment and electric system thermal, voltage, and stability limits" should be transferred to SAR #2 addressing facility ratings, operating limits, and transfer capabilities.</p> <p>Other comments: <i>Assessment of future needs and development of transmission plans is highly related to commercial processes. As in other markets, information needs to be collected to assess future ability of the market participants to respond to market requirements. This SAR should be coordinated with business practices for the industry.</i></p> <p>The phase I am recommending be moved to SAR #2, which appears to encompass standards presently covered by Planning Standards I.A (Table 1) and I.D, is the major component that makes this SAR a core reliability requirement. My rationale for moving this to SAR #2 is included in the comment form for that SAR.</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: The "Assess Transmission future needs and develop transmission plans" SAR does not state a requirement to plan the system so that it can be operated within operating limits. I feel that this terminology (operating limits or other term such as Operating Security Limits) should be common among all SARs. The system must be planned so that it can be operated reliably. Using this terminology in all SARs would provide the appropriate link among them.</p> <p>Without knowing the details that will be included in the standards as described by these SARs, it is difficult to make an assessment on the completeness of this set of SARs. I feel that there should be a SAR that requires LSEs, distribution providers, and generators to respond to requests that will have the effect of operating the system within Operating Limits.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be expanded to include: Planning must be coordinated to optimize not only transmission but generation as well. The left alone process of disjointing generation and transmission is creating a non-steady state electrical system. The criteria for designing a system must include defined measurements adopted by all. This brief description does not provide sufficient detail to ensure reliability is planned. The planning criteria must address defined transmission planning for transfer usage as well as specific load service usage in other words interconnection as well as intraconnection. The need to define roles, responsibilities and authority must be developed between Federal (RTO) characteristics and functions and transmission owners.</p> <p><input type="checkbox"/> The scope of the SAR should be reduced to eliminate:</p> <p>Other comments: Transmission Operator and perhaps Distribution Provider should be added to the list of applicable functions.</p>

<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be reduced to eliminate: Reference to standardization of the solution set for the transmission plan (see Brief Description section). Mirant is concerned that the standard goes beyond assessment and planning of the bulk transmission system, delving into definition of the methods for meeting the plan. Per the <i>Market Interface Principles</i> (principle 4), the standard should not inhibit commercial/market solutions.</p> <p><i>Other comments:</i></p> <p>Mirant believes that the standard should not apply to the Transmission Owner function, consistent with the <i>Functional Model</i>.</p>			

SRP Comments on NERC 11 SAR sent out on April 2, 2002.

All 11 SAR's (this group of 10 plus the one sent out earlier) don't contain enough information to make the kind of judgments requested on the forms. Therefore the forms are not filled out.

We recommend all the SAR's be advanced to the next step to develop the specific standards and associated measurements for each standard so that we can evaluate and comment on them.

All of these SAR's are needed for reliable planning and operation of the bulk electric transmission system and meet the principle requirements.

Comments on the White paper:

1. The paper fails to state what standards are supposed to be. This seems so basic; one has to assume that those drafting the white paper want to redefine the definition contained in the Organizational Standards Manual. This leads to a lot of confusion and is not the place to do that.
2. The Planning Standards were written in a different time period than the Operating Policies with different objectives. Thus they are different and that should be recognized. For instance the development of a Planning Functional model has absolutely nothing to do with whether control areas exist or not and whether companies have restructured or not. The statement about control areas may be true for the Operating Policies but it is not true for the Planning Standards.

The Planning Standards (Templates) were written to meet the definition of a standard in the Organizational Standards Manual, to meet at least one of the Reliability Principles, to comply with all the Market Interface Principles and to contain the compliance administration elements. This is very different than what is contained in the Operating Policies. The Planning Standards need to go through the new process so that both the Operating elements and Planning elements of the Organizational Standards are consistent, are not duplicative and are needed for reliability.

3. The term "core reliability requirement" is used in the white paper but is never mentioned in the Organizational Standards Manual. Using an undefined term is very misleading and should be avoided.
4. The paper in several places address "what performance must be achieved". As noted above, an Organizational Standard can be broader than that and this write up is misleading.
5. The process has been lengthened because of the multiple posting of the SAR's. NERC has a body of reliability requirements written up into Compliance Templates. With very little effort these could be written up into SAR's that would provide sufficient detail for NERC to evaluate them. It is very hard to comprehend why one does not use this work to expedite the process. Instead SAR's are sent out with insufficient information. The process is long enough. We should be looking for all ways possible to speed it up.

Comments on the SAR write-up:

1. The SAR write-up only contains the purpose and brief description of a standard. Where is the Standard? I thought that is what the SAR is for?
2. The descriptions are in most cases extremely vague. The write-ups contain words like "such as" or "as defined in the standard". These are big enough to cover a MAC truck. Once again there is insufficient information to make a good judgment.

April 29, 2002

Guy V. Zito
Manager, Planning
Northeast Power Coordinating Council
1515 Broadway Floor 43
New York, NY 10036

RE: NEPOOL Compliance Working Group (NCWG) comments pertaining to the 10 Standard Authorization Requests (SARs) posted for open comment

The NCWG has reviewed the 10 SARs posted for open comment and has agreed they are core standards, which serve a purpose in support of reliability.

Standard Title:

Prepare for and Respond to Abnormal or Emergency Conditions
Prepare for and Respond to Blackout or Island Conditions
Coordinate Interchange
Coordinate Operations
Monitor and Analyze Disturbances, Events and Conditions
Operate Within Limits – Monitor and Assess Short-term Transmission
Define (Physical) Connection Requirements
Design, Install, and Coordinate Control Protection Systems
Assess Transmission Future Needs and Develop Transmission Plans
Determine Facility Ratings, Operating Limits, and Transfer Capabilities

We do not agree that the **SAR Type** is a new standard. We suggest that at a minimum the SAR should indicate the existing standard and whether or not it will be withdrawn when the revised standard is adopted. We suggest that NERC stop the open process of reviewing existing policies and standards if these Organizational Standards will replace them. NERC should clearly indicate that one purpose of the Organizational Standards Process is to replace existing standards.

Sincerely,
Daniel L. Stosick

<i>SAR Commenter Information</i>			
Name	Paul Rocha		
Organization	Reliant Energy HL&P		
Telephone	713-207-2768	Fax	713-207-2281
e-mail	paul-rocha@reliantenergy.com		
<p>Reliant Energy HL&P ("HL&P") files these comments regarding the ten Standard Authorization Requests (SARs) discussed below. Please note that HL&P is the regulated electric utility operating in and around the area of Houston, Texas, within the ERCOT region. HL&P does not represent Reliant Resources, the unregulated energy services company operating in various areas of North America and Europe. Reliant Energy expects to spin off Reliant Resources later this year. In anticipation of the pending separation, HL&P and Reliant Resources are operating in large part as two separate companies. It is HL&P's understanding that Reliant Resources may separately provide comments regarding these SARs.</p>			
<p>HL&P agrees that there is a need for a standard for assessing transmission future needs and developing transmission plans. We support ERCOT's comments, which either have or will soon be filed, regarding the appropriate scope and characteristics of such standards. However, we believe a prospective NERC planning standard should apply to interstate and international electric systems only, and should not apply to intrastate electric systems such as ERCOT, as explained more fully below.</p> <p>The assessment of need and development of transmission plans should strive for an appropriate balance between ensuring reliability, maintaining reasonable transmission rates, mitigating congestion costs, and avoiding unnecessary landowner impact. For intrastate transmission systems such as ERCOT, HL&P believes that the appropriate place to balance these objectives is within the intrastate region itself, since the ERCOT organization, and the standards it develops, are subject to state commission review and approval. That same state commission (the Public Utility Commission of Texas) also has rate-setting and line certification authority, and thus is uniquely positioned to balance the conflicting objectives involved in transmission system planning. However, for interstate and international regions, it may be appropriate for NERC to develop a transmission planning standard. Recognizing that NERC does not have rate-setting or line certification authority, NERC should guard against establishing one-dimensional standards that fail to take into account all the dimensions that guide the transmission planning process.</p>			

<i>SAR Commenter Information</i>			
Name	Brant Eldridge		
Organization	ECAR		
Telephone	330-580-8005	Fax	330-456-3648
E-mail	brante@ecar.org		
<p>ECAR has conducted a survey of its member companies regarding the eleven SARs, which NERC has initiated to-date. We recognize that the comment period for the first SAR issued ("Balance Resources and Demand") has already closed. However, considering that the first SAR was issued earlier than the other ten primarily just to get the process started, and further considering that all 11 SARs are viewed by NERC as a possible complete set of Organization Standards (re: the "White Paper"), ECAR believes that comments on the first SAR should still be considered along with those on the other ten.</p> <p>11 of the 18 ECAR Full Members, along with two Associate Members, submitted responses to the SAR survey. Some of the responses were submitted using the NERC "SAR Comment Form", while others were contained in narrative e-mails, and one was faxed to us. Therefore, a complete set of the ECAR member company responses will be sent to the Standards Process Manager at NERC via Fed Ex to arrive at NERC by May 3rd. The Fed Ex package will include a copy of this e-mail. FYI, NERC may also receive some of the ECAR member company responses directly from the companies. Some of the individual company responses will be identical to what will be in the Fed Ex package and some will contain more detailed comments.</p> <p>The ECAR member company responses contain numerous and wide-ranging comments about the need for each of the 11 proposed Organization Standards, as well as comments regarding the scope and applicability of the SARs. As your review of these responses will show, there is general ECAR consensus – but not unanimity -- that the 11 SARs as a set cover the scope of performance needed to ensure reliability of the interconnected North American bulk power systems. Some ECAR members feel that there are performance areas not covered in the proposed set of Organization Standards, and they have provided what they think is missing. Others believe that some of the proposed Organization Standards are not needed, and they explain why they feel that way. Numerous comments were directed at the scope and applicability of the SARs. Several ECAR companies questioned the inclusion of the "Distribution Provider" function in the applicability section of the SARs, believing that NERC should stick to its traditional focus on the bulk power systems and stay out of the distribution arena.</p> <p>The recent call for nominees to serve on SAR Drafting Teams is the appropriate next step. ECAR believes that all 11 SARs need to be refined to reflect industry comments and then posted again for another round of industry comments. Before proceeding into actual development of Organization Standards based on these 11 SARs, NERC must have clear industry consensus on the need for each of the Organization Standards outlined in the 11 SARs, as well as consensus on the scope and applicability of those SARs.</p> <p>If the wide-ranging comments received from ECAR members are any indication, there is still some serious work to be done to achieve the needed clear industry consensus on how to proceed.</p>			

East Kentucky Power Cooperative (General Comment)

EKPC believes our present standards are adequate and therefore is not in favor of developing a new set of standards. We also believe the new process should be revised to provide for a screening committee to evaluate proposed standards before they are presented to all NERC members for comment. However, given that we are going to develop new standards with this process, EKPC endorses all eleven of the SARs. Thanks, Paul Atchison.

LG&E Energy (General Comment)

LG&E agrees there is a need for the eleven proposed organization standards. However, we do see a disconnect with their development and operating procedures/protocols of RTO's. Where will this coordination take place to ensure consistency, eliminate redundancy, and application particularly since there will most likely be more than 1 RTO at the time of issuance?

VECTRON - Southern Indiana Gas & Electric (General Comment)

The NERC Proposed Organization Standards appear to me to cover the scope of performance needed to insure reliability of the interconnected grid. The scope of the SARs as proposed, also, look fine to me.

Dayton Power & Light (General Comment)

We are okay with the 11 proposed Standards.

American Electric Power is providing the following comments on the 10 most recent Standard Authorization Requests (SARs) to ECAR as input to the formulation of ECAR's response to NERC. AEP looks forward to working with ECAR and NERC as well as other market participants to ensure the continued reliability of the electrical system.

Clearly the electricity industry has been exceptionally dynamic and fluid in recent years and is going through many changes. While changes can be positive, it is incumbent on the industry to ensure that changes, which are adopted result in enhanced reliability and a better market environment. With this in mind, we envision that there are actually three interrelated but separable processes with respect to the development of standards.

First, the relevant standards need to be identified. Over recent months this has been referred to as defining "what" the standard is.

Second, there need to be decisions about "how" these standards are to be achieved.

Third, choices have to be made as to how these standards will be implemented.

The resultant standards, when implemented and operational, will potentially affect production, consumption and investment decisions. By necessity, the standards, including how they are achieved and implemented, are closely related to the design of the market and the separation of functions among market

participants and service providers. For this reason, we encourage discussion and even preliminary definition of what core reliability standards are needed. However, we strongly urge restraint with respect to the other two aspects of the process - defining how the standards will be achieved as well as how they will be implemented. In our opinion, the latter two processes are highly integrated with the process of market design and implementation as well as market operation; the development of RTOs; and the definition of the NERC/NAESB interface.

Given that closure on many of the market design issues is expected in the near future, we see little risk in delaying the latter two processes - how the standards are achieved and implemented-- until such time as clarity is achieved on Standard Market Design (SMD) and RTO formation. Moreover, since the NERC/NAESB interface will likely impact decisions on how standards will be achieved as well as how they will be implemented, it seems logical to wait until that interface has been defined.

We think it would be beneficial for NERC to recognize that nothing is gained by deciding how the standards will be achieved (including implementation) at this stage of the debate on Standard Market Design and the RTO development process. We would prefer to see the SAR process simply make the threshold determination as to whether any of the proposed standards are needed, and then put on hold the actual development of those standards that are needed until the critical market development activities described above are closer to completion. AEP is reviewing the SARs with particular emphasis on their scope, both individually and collectively, and we plan to provide appropriate comments to NERC by May 3.

Consumers Energy (General Comment)

Consumers Energy opposes all 10 of the SARs on their present form. We understand that it is too late to vote on the 11th SAR.

The concern that we have is that there is only limited ability to prevent new requirements from being incorporated with the old, standard reliability requirements. The SAR descriptions sound good because they espouse the old, tried and true reliability concepts that we have known and loved from the past. If there was an effective way to limit the resulting practices to those traditional values, I would be the first to support them. Unfortunately, we are not voting here on codification of the current practices. We, instead, are voting to develop a set of practices that will include the currently unknown and possibly oppressive, unacceptable set of future requirements. This vote has nothing to do with the tried and true practices from the past. Its about accepting an unknown set of requirements on faith and trust ... that none of the practice developers will be out to do us harm.

The standard argument here is that the SARs are only scope setting documents and that we will still have a change to shape and to vote on the actual standards when they go through the final approval stage. If we believe this argument, we are totally ignoring the lessons from the past. There is no guarantee that ECAR will have any personnel involved in the development of the final practices. It is unclear how many people will be involved in the drafting of the practices nor how they will be selected.

The biggest single concern is what the final product will look like and how it will be voted on. I would make a modest wager that it will consist of a handful of standard practices that we all could accept (and in fact would insist upon) along with three practices that are new and totally unacceptable. We will be faced with the proposition that we must vote on the "package" of practices where we must accept the bad ones to get the good ones. I can find no reference to a line item voting procedure.

The solution to this problem is to suggest a provision in all ten SARs that the final package of practices will not include any policies that are not already in the NERC approved set of policies and standards. Consumers Energy could then support all ten SARs.

C.V. Waits

Duquesne Light Company (General Comment)

OPERATIONS AND ASSET MANAGEMENT

System Operations

Transmission Business

TO: Brant Eldridge
FROM: J. F. Rosser
DATE: May 8, 2002
SUBJECT: NERC "Organizational Standards"

In response to your memo of April 19, 2002, Duquesne Light Company presents the following comments concerning the eleven "Standard Authorization Request" (SAR) Forms. Generally, the proposed standards seem to simply restate today's standards and label them as "new" Organizational Standards. Specifically, the proposed SAR titled "Balance Resources and Demand" is really a restatement of the current Disturbance Control Measure, CPS1, CPS2 and a new Frequency Response Measurement. This SAR, as represented at the CRC meeting, was to provide an example of how other SARs should be composed.

1. The purpose of the standard is stated as; Maintain scheduled Frequency within an Interconnection.
2. The Industry need includes Arrest Sudden frequency changes; Prevent Time error; Prevent Operation of Underfrequency Relays, prevent line loading limits violations, minimize inadvertant interchange.
3. Standards include; a measurement (FRM) to ensure automatic throttle controls are available to arrest frequency changes, a measurement (CPM1) to ensure adequate generation control regulation to maintain scheduled frequency, a measurement (CPM2) to ensure unscheduled power flows do not occur which could cause transmission operating limit violations, a measurement (DCM) to ensure scheduled frequency is maintained after a disturbance.

It is evident that this SAR's Title, Purpose, Need and Measures are inconsistent with each other, mixing frequency schedules and inadvertant accumulations with transmission loading violations and time error. Also, certain "Needs" and "Standards" are inconsistent with the NERC BOT decision to not pursue the development of business practices (i.e., minimization of inadvertant accumulations, timer error accumulations, etc. are equity issues and not related to reliability concerns).

Furthermore, suggested are measures that better relate to other Standards. For example, transmission limit violations fit better into "Monitor and Assess Short Term Transmission Reliability" – operate within limits. When considered under that alternate standard, this measurement may not survive because other measurements may be deemed more appropriate.

Look at the SAR from a purely technical approach. In doing so, Duquesne Light suggests that the title of the Standard "Balance Resources and Load" should be rewritten to be "Maintain Scheduled Frequency".

The Purpose of Standards would be to maintain Interconnection frequency within acceptable limits.

The Industry Need would be to prevent damage to customer equipment and to prevent unstable operations related to disturbances.

The Standard should include a description of acceptable frequency along with a technical defense of the standard including standard generator limits, motor limits, etc.. See ECAR Document #3, Appendix 1, (attached) as an example.

The Standard should include adherence to accepted industry practices such as the installation of underfrequency relays, automatic governor control requirements, etc. including the operation of this equipment within limits specified within the standard.

Measures and Requirements may include:

1. a measurement similar to CPS1
2. annual audit of underfrequency load shedding equipment, levels, and set points
3. annual audit of the status and condition of automatic governor controls
4. monitoring of frequency excursions related to disturbance conditions (Security Coordinator)
5. Coordination of interchange schedules

Measurements should not include:

1. DCM because it duplicates CPM1 and is not frequency sensitive
2. CPM2 because it purports to protect against transmission loading violations related to SAR #6

If NERC would consider business practices, the ECAR Inadvertant Settlement Process could be incorporated into the standard with a longer range target of replacing energy banks with a pay as you go policy, possible tied to adders (\$/MWH) related to system frequency deviations from schedule. Otherwise, NAESB would develop these business practices.

The following are Duquesne's comments on the other 10 proposed SARs.

1. Assess Transmission Future Needs & Develop Transmission Plans – Appropriate
2. Determine Facility Ratings, Operating Limits and Transfer Capabilities – Appropriate
3. Design, Install, Coordinate Control and Protection Systems – Appropriate
Standard should be expanded to include coordination between Transmission Owners, Transmission Operators, etc.
4. Define (Physical) Connection Requirements – Inappropriate as a stand alone SAR
This SAR should be included in SARs #2, #3, #6, #7, #8, #9, #10, #11
5. Previously reviewed
6. Operate Within Limits – Monitor & Assess – Inappropriate as a stand alone SAR, but should be incorporated with SAR #8. Coordinated operations are required to ensure limits are not violated.
7. Coordinate Interchange – Inappropriate as a stand alone SAR. Should be part of SAR #5.
8. See review of SAR #6.
- 9., 10., and 11. Should be incorporated into SAR #6/#8 and/or #5 as modified by DLC

In conclusion, Duquesne Light applauds the NERC SAR initiative. NERC must, however, take care to not simply allow this initiative to be a restatement of existing standards

and application of performance measurements that miss the target. Care must be taken to identify the exact technical need/purpose (quantifiable) for each performance standard, ensuring that each performance measurement ties precisely with a stated need/purpose in support of the standard (e.g., A Standard whose purpose is to maintain frequency should not be tied to a need to limit unscheduled power flows that can cause operating limit violations but should be tied to general turbine-generator requirements).

Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?			
<input type="checkbox"/> Yes <input checked="" type="checkbox"/> No			
What is missing from the NERC set of SARs?			
<ol style="list-style-type: none"> 1. Load forecasting, generation capacity, and capacity margin analysis. 2. Generation operating requirements: <ol style="list-style-type: none"> a. Voltage schedule produced and followed b. Voltage control kept on automatic c. Generator controls with a 5% or less droop d. Speed control (frequency) on automatic e. Record the times and reasons when speed control, voltage control, or voltage schedule were not on automatic. 3. Reliable construction and maintenance standards for transmission lines, transmission substations, and generation substations. 4. Control Area tie-line tripping for conditions of: <ol style="list-style-type: none"> a. Under frequency b. Overload c. Instability d. Voltage collapse 			
<p>Note that item #4 was not included in the old NERC Reliability Standards. We did not have the technical ability to properly manage these conditions for at least the first twenty years of NERC. We now have the technical ability to predict and operate at the points of no recovery for these conditions and should not do so, to:</p> <ol style="list-style-type: none"> a. Reduce the number of Control Areas Blacked Out by a major disturbance to the interconnected grid. b. Make Safe Unit Shut Down Power from neighboring control areas much more available. c. Make Unit Restart Power much more available from neighboring control areas. d. Make Load Restoration Power much more available from neighboring control areas. e. Reduce Dependence on questionable black start plans. f. Never disconnect a control area from the interconnected grid, unnecessarily. 			
<p>All that is needed at this time for this item #4 is that the five ECAR technical panels involved (OP, TSPP, TFP, GFP, PP) develop a set of guides for these four conditions for which tie lines should be tripped. Then, any control area that would like to obtain the six advantages listed above, would have a solid well thought out set of guides to start from. (I would be glad to help any of the technical panels with the details. Lew Gray)</p>			
Is there a reliability-related need for an Organization Standard to be developed on this topic?

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing:</p> <p>General Comments:</p> <p>1) Even though the Standards drafting committee is to be fairly small (8 or 9, I believe), there needs to be a committee VOTING process for deciding on the final proposed wording or a Standard.</p> <p>2) There needs to be a formal face to face forum for reviewing SARs after the drafting committee has done its work. Some have proposed the current Standing Committee meeting as this forum. As long as the meetings match up with the Standards development timeline, this would be OK.</p> <p>3) We also support the submittal of the actual Standards Development process through the SAR process. The current process was developed without any "due process" or formal approval process prior to the BOT adoption.</p> <p>4) We still believe that there are too many Segments in the NERC process.</p> <p>5) The new NERC standards development should be completed and receive ANSI approval before development begins on the new standards contemplated by these SARS. Proceeding with SARS before the new standards process is in place ensures that significant re-work will be required.</p> <p>6) The industry is already stretched very thin supporting the many NERC and FERC initiatives. The number of SARs proposed at one time is excessive. Also, there will be inevitable overlaps and conflicts between the various SAR drafting groups. Only 1 or 2 SARs should move forward at one time.</p> <p>7) The time provided to review and comment on such a large number of SARs was insufficient to do a thorough review and provide accurate and complete comments.</p> <p>The "Assess Transmission future needs and develop transmission plans" SAR does not state a requirement to plan the system so that it can be operated within operating limits. We feel that this terminology (operating limits or other term such as Operating Security Limits) should be common among all SARs. The system must be planned so that it can be operated reliably. Using this terminology in all SARs would provide the appropriate link among them.</p> <p>Without knowing the details that will be included in the standards as described by these SARS, it is difficult to make an assessment on the completeness of this set of SARS. We feel that there should be a SAR that requires LSEs, distribution providers, and generators to respond to requests that will have the effect of operating the system within Operating Limits.</p> <p>Maintenance requirements should cover transmission equipment other than just protection and control equipment.</p> <p>A lot of vital requirements of existing policies are not included in any of the proposed SARS, i.e., time error correction, inadvertent, etc.</p> <p>The main power equipment design, installation, and maintenance requirements are not adequately addressed in these SARS (i.e. circuit breakers, transformers, transmission lines, etc.). Should also address transmission line right-of-way maintenance.</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed:</p> <p>It appears that some of the SARS overlap and cover some of the same areas, such as "Prepare For and Respond to Emergency Conditions", "Prepare for and Respond to Blackout or Island conditions", and "Monitor and Analyze Disturbances, Events, and Conditions". These could all fall under a single Emergency Operations SAR. "Coordinate Interchange" should also fall under "Coordinate Operations". In addition, the SARS are intended to define standards for core reliability functions, i.e., "who to do". Some of the SARS really describe processes (i.e., "how to do it") rather than define standards, such as the SAR on "Determine Facility Ratings, Operating Limits and Transfer Limits". There are others that may need to be combined-it is suggested that a remapping of policies to specific SARS should be done.</p>			
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input type="checkbox"/> The scope of the SAR should be reduced to eliminate:</p>			

Other comments: For the Applicable Functions, TSP, T-owner, and T-operator could all apply. We question whether RA should be applicable. Was the RA inclusion possibly a holdover from when the Planning Authority was not developed?

The scope of this SAR seems rather large, perhaps it could be divided into more manageable pieces.

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid? <input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing:</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: Core organization standards for reliability must be specific and offer measurable boundary conditions to achieve reliability objectives. Additionally, these standards should not presume that procedural requirements to achieve reliability objectives are included as part of a core reliability standard. Procedures may be necessary for entities to follow to meet NERC Organization Standards requirements. Most procedures meant to achieve reliability objectives contain impacts on the operations of the marketplace. The inextricable link between the reliability needs and the market needs makes the development of reliability-driven procedures impossible to do in a NERC reliability - focused process. If NERC proceeds to develop the core organization standards for reliability, there must be close coordination with entities, such as NAESB and RTOs, that will develop market-driven procedures so that a proper procedure can be developed to meet both reliability objectives and commercial needs.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic? <input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be reduced to eliminate: any reference to criteria to be determined by boundary conditions established outside a measurable or quantifiable standard. A core standard for reliability should be specific and measurable. This SAR proposes that a standard be "a plan" that encompasses normal, abnormal, and extreme system conditions and not define what those conditions are. The plan is a solution - not a measurable standard. As stated in the SAR, "...the plan may utilize operating, construction, and market solutions..", there are numerous possible methods to facilitate the reliability need this SAR suggests. These methods revolve around market operations and should be developed in a process that considers all market interests and weigh those against a measurable reliability need. The proposed standard should be focused on the measurable and definable boundary conditions for "normal, abnormal, and extreme system conditions."</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing:</p> <p>The proposed set of 11 Standards are described in very generic terms with few details. Therefore it is not possible to assess whether or not the set of these 11 organization standards is complete with respect to some or all areas of power system performance from reliability perspective. For example, there should be a standard for Power System Model (power flow, short circuit, dynamics, EMTP) Development along with corresponding Data Verification requirements. Is model building and data verification encompassed by the presently proposed set of standards? If so, there should be a separate stand-alone standard for it, because most, if not all, reliability and marketing decisions for performance and use of the transmission system are based on the analyses using this data. Providing timely, verified, and appropriate data should be the responsibility of all the users of the transmission system.</p> <p>There also should be a standard for wide-area coordinated system planning. Is wide-area coordinated planning addressed by the proposed standards? While some level of coordination in planning and operation exists today, this level of coordination needs to be increased. Again, an RTO should facilitate coordination among its members and neighbors, but a standard for wide-area (beyond the boundaries of transmission owning entity, RRO, or RTO) planning would ensure that it is done on a regular and consistent basis.</p> <p>Much effort (several man-years) was expended in the recent development of the NERC Planning Standards. It would seem that the main emphasis of those standards is still relevant. While we are not sure whether or not or how those standards would be used in this SAR process, we believe that at the very least, they should be used as starting points from which new standards can be developed that can wrap around the NERC Functional Model.</p> <p>Not being involved in this process from the beginning, I am not sure what was considered in determining which existing standards belong in the proposed set of 11 as a separate standard. It would appear that Coordinate Interchange (SAR#7) and Coordinate Operations (SAR#8) could be combined into one Organizational Standard as could Prepare for and Respond to Abnormal or Emergency Conditions (SAR# 10) and Prepare for and Respond to Blackout or Island Conditions (SAR#11). Similarly, it appears that the proposed SAR#2, Determine Facility Ratings, Operating Limits, and Transfer Capabilities should be separated into three SARs.</p> <p>Either in these Standards or The NERC Functional Model, a clear definition of who is ultimately responsible for compliance with the standard is required. For example, which entity assumes the ultimate responsibility for long term system planning? Is it ISO, RTO, ITC, Transmission Owner or Transmission Provider? As the function definition of the Planning Authority has not been defined yet, it is not certain that it would provide an answer to this question. In any case, responsible entities should be very clearly defined for compliance with each proposed standard or the new standards.</p>			
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be expanded to include: More details to judge whether or not all reliability related activities are covered or not.</p> <p><input type="checkbox"/> The scope of the SAR should be reduced to eliminate:</p> <p>Other comments: The purpose and description is too general. This standard may require to be split into two or more SARs.</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid? <input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: N/A</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: Entergy believes there are three "core reliability" Organization Standards needed that constitute "what" is needed for reliability:</p> <ol style="list-style-type: none"> 1) Balance Resources and Demand, 2) Operate Within Thermal, Voltage and Stability Limits, and 3) Coordinate Operations. <p>All the other eight SARs, including other processes like TLR, constitute "how" these three "core reliability" Organization Standards are met. The remaining eight SARs do not rise to the level of "core reliability" Organization Standards. These eight should be developed as processes, either by the industry within the three Organization Standards or by individual industry owners/participants. For instance, the E-Tag system was developed by the industry, facilitated by NERC, and is one part of the process for meeting the intent of "Coordinate Interchange", which itself is a process under "Balance Resources and Demand" and/or "Coordinate Operations". The existing TLR process was developed by the industry to assist industry participants meet the core Organization Standard "Operate Within Limits - Monitor and Assess Short-Term Transmission".</p> <p>Others of the SARs should be developed by individuals but do not themselves rise to the level of "core reliability" Organization Standard. For instance, every system operator should have plans for recovering from blackout or islanding conditions, "Prepare for and Respond to Blackout or Island Conditions". However, we believe these processes should be developed by individual operators, unique to their own systems, and are not core Organization Standards.</p> <p>Further comments on the individual SARs are included below for your consideration.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic? <input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input type="checkbox"/> The scope of the SAR should be reduced to eliminate:</p> <p>Other comments:</p> <p><i>This SAR is really a requirement to establish a "process" for assessing and planning the transmission system. We view the contents of this SAR to be one of the "how"s for meeting the renamed Organization Standard "Operate Within Limits - Monitor and Assess Short-Term Transmission" . As such, this SAR does not rise to the level of "core reliability" Organization Standard.</i></p> <p>The industry currently has in place regional processes for assessing and planning the power system under a variety of normal, abnormal, and extreme system conditions. The process should be continued, updated if necessary, and participation in the process should be a required activity by all industry participants.</p>

E-mail	mddesselle@aep.com		
<p>American Electric Power (AEP) appreciates the opportunity to comment on the 10 most recent Standard Authorization Requests (SARs) and looks forward to working with NERC and other market participants to ensure the continued reliability of the electrical system.</p> <p>Clearly the electricity industry has been exceptionally dynamic and fluid in recent years and is going through many changes. While changes can be positive, it is incumbent on the industry to ensure that changes, which are adopted result in enhanced reliability and a better market environment. With this in mind, we envision that there are actually three interrelated but separable processes with respect to the development of standards.</p> <p>? First, the relevant standards need to be identified. Over recent months this has been referred to as defining “what” the standard is.</p> <p>? Second, there need to be decisions about “how” these standards are to be achieved.</p> <p>? Third, choices have to be made as to how these standards will be implemented.</p> <p>The resultant standards, when implemented and operational, will potentially affect production, consumption and investment decisions. By necessity, the standards, including how they are achieved and implemented, are closely related to the design of the market and the separation of functions among market participants and service providers. For this reason, we encourage discussion and even preliminary definition of what core reliability standards are needed. However, we strongly urge restraint with respect to the other two aspects of the process – defining how the standards will be achieved as well as how they will be implemented. In our opinion, the latter two processes are highly integrated with the process of market design and implementation as well as market operation; the development of RTOs; and the definition of the NERC/NAESB interface.</p> <p>Given that closure on many of the market design issues is expected in the near future, we see little risk in delaying the latter two processes – how the standards are achieved and implemented - until such time as clarity is achieved on Standard Market Design (SMD) and RTO formation. Moreover, since the NERC/NAESB interface will likely impact decisions on how standards will be achieved as well as how they will be implemented, it seems logical to wait until that interface has been defined.</p> <p>We would prefer to see the SAR process simply make the threshold determination as to whether each of the proposed standards are needed, and then put on hold the actual development of those standards that are needed until the critical market development activities described above are closer to completion. Only at that point in time, will it be known whether the proposed standards cover the scope of performance needed to ensure reliability of the interconnected North American Grid. In the interim, AEP looks forward to continue working with NERC, NAESB and other market participants to develop and implement the appropriate standards.</p> <p>Other comments: It is unclear to AEP what the intent was of this SAR . This SAR appears to have both market and reliability implications. As such, before moving forward to develop this SAR, AEP requests a further clarification of the specific intent. To the extent that this SAR is transitioning an existing standard from the old world to the new world (Functional Model), then the standard should not go beyond the original scope. Consistent with our general comments, once the clarity is achieved on Standard Market Design and RTO formations, then this standard should be revisited and reevaluated.</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing:</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: General comment on entire set of SAR's and the overall process: Based on the short descriptions and the broad scope of most of these SAR's, it appears that these SAR's will encompass many of the existing planning and operating templates developed during the NERC pilot program. Experience obtained during the pilot program showed that many of the planning templates and some of the operating templates were difficult to interpret and even more difficult to measure for compliance, let alone determine exactly who the templates applied. Based on the scope descriptions given for each SAR, it appears these SAR's are written to encompass those same templates. Hopefully, the final standards will be written such that each standard is clear and concise as to how exactly the entity must comply for different levels of compliance and exactly which entities must comply for each measure of each standard. With the benefit of experience of the pilot program, Cinergy would like to suggest that since several of the measures in the existing templates are difficult if not impossible to actually measure for compliance, that some of these proposed standards or portions thereof not be developed into standards but instead be written as "good engineering practices". These "practices" could be used in the certification process for the various functions in the NERC Functional model such as Reliability Authority, Planning Authority, etc. We will try to indicate on each SAR, those portions that should be written as "practices". In the event that all eleven of these SAR's are approved to move forward, then the list should be prioritized and developed somewhat consecutively instead of simultaneously. We have already observed how difficult it is to stay abreast of the templates developed during the pilot as far as providing meaningful comments and review due to the sheer volume of documents distributed for review. Although there are only eleven SAR's, each SAR encompasses multiple measures, which will need to be defined in order to specify how each part is to be measured for compliance and to define what entities must comply for each part. Also since technical experts will be required to assist in the development of these standards, there will be a burden on resources if all of these are developed simultaneously since many of the standards could involve some of the same experts. The priority of developing each standard should be based on industry consensus of what are the major problems/issues that are threatening the reliability of the transmission grid today. Standards should be written so that performance can be measured as it affects overall grid reliability vs trying to measure practices or procedures.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be reduced to eliminate: entire standard</p> <p>Other comments: This SAR should be developed as a "practice" to be used in the certification process for Planning Authorities and Reliability Authorities. Experience with the existing templates and NERC Table 1A shows how difficult it is to not only determining how to comply with this standard but to actually measure it for compliance. It is difficult if not impossible to determine if events will result in "cascading" - usually engineering judgment is used. It is also not practical to investigate every possible extreme or abnormal system condition to check for "cascading" - again engineering judgment is used. All of these factors makes measuring an entity for compliance very difficult if not impossible. Based on the ongoing development of RTO's and the open stakeholder process proposed for future planning studies, it does not appear that lack of planning will be an issue.</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: (1) ATC applauds the effort of the SAR's to acknowledge the dismantling of the vertically integrated utilities. However, some care needs to be given to defining the separated groups. For example, it is not always clear what is meant by Planning Group, Transmission Owner, Transmission Service Provider, and Transmission Operator, whether some groups are included in others, and whether there should or shouldn't be that inclusion. For each of the SAR's, there was some lack of confidence that the correct complying entities had been identified.</p> <p>(2) Perhaps buried within the SAR's is a modeling component that will surface in the details, but none of these SAR's will accomplish their intent without credible models from which to do analysis.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be expanded to include: SAR #8 includes coordinated "planning". This language should be added here so that the Assessing and Planning of the Transmission System is coordinated. If modeling isn't addressed in the details it should be.</p> <p><input type="checkbox"/> The scope of the SAR should be reduced to eliminate:</p> <p>Other comments: (1) It is not clear how market solutions would fit in providing reliable delivery of power for the future needs of customers. Market solutions could provide an interim solution to transmission constraints but they should not be used in planning future transmission needs.</p> <p>Maybe the transmission service provider (TSP) should have some responsibility within this area as it relates to providing adequate transmission service to the market. If the TSP identifies a bottleneck on the transmission system creating problems transferring energy across the system, that should be included in future plans to try to eliminate that bottleneck.</p> <p>The transmission operator, if not the same as the transmission owner, should have some responsibility in making sure the transmission owner knows about future improvements needed to improve it's system from an operational perspective.</p> <p>(2) NERC should ensure that the standards defined within this SAR include a definition of how the planning model is created. Is there any way to come up with a standard for what gets included in the future models? For example, roll-over rights for transmission service, proposed generation facilities, proposed transmission facilities that require state approval and/or significant right-of-way acquisition.</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: A lot of vital requirements of existing policies are not included in any of the proposed SARS, i.e., time error correction, inadvertent, etc.</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: It appears that some of the SARS overlap and cover some of the same areas, such as "Prepare For and Respond to Emergency Conditions", "Prepare for and Respond to Blackout or Island conditions", and "Monitor and Analyze Disturbances, Events, and Conditions". These could all fall under a single Emergency Operations SAR. "Coordinate Interchange" should also fall under "Coordinate Operations". In addition, the SARS are intended to define standards for core reliability functions, i.e., "what to do". Some of the SARS really describe processes (i.e., "how to do it") rather than define standards, such as the SAR on "Determine Facility Ratings, Operating Limits and Transfer Limits". There are others that may need to be combined - it is suggested that a re-mapping of Policies to specific SARs should be done.</p>

Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?			
<input checked="" type="checkbox"/> Yes <input type="checkbox"/> No - see comments			
If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing:			
If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed:			
Comments:			
The proposed standards appear to provide the necessary coverage to ensure a reliable interconnected North American grid. A thorough review will need to be done to ensure that no necessary and significant performance requirement is missed that is in the current Operating Policies and Planning Standards. While the proposed SARs may cover the scope of performance needed, we have several concerns with the overall set at this stage of implementation;			
<ol style="list-style-type: none"> 1. The 'White Paper on NERC's set of Organizational Standards', dated April 11, 2002, clearly articulates a direction with which we agree. The paper proposes that 'these standards will define what performance must be achieved, without providing restrictive measures on how to achieve that performance'. This direction arose following industry experience with the very large set of current planning and operating standards and recognition by the industry that the current standards, in many areas, are too prescriptive of the 'how'. By focusing the industry on meeting less meaningful standards, the goal of maintaining reliability is actually put at risk. It is our belief that the proposed set of standards still focuses too much on the 'how', to the potential detriment of the overall objective. 2. Perhaps the most important aspect of a set of organization standards is to define to whom and to what the standards apply. The NERC Functional Model does a good job of providing a framework to define to whom the standards apply. However, what the standards apply to is left almost entirely open. What the standards apply to is variously described in the proposed SARs as the; transmission system, interconnected transmission system, network, power system, bulk electricity system and those facilities which affect reliability, among others. The white paper again provides valuable insight by defining the objective in terms of the 'interconnected electric systems in North America', however, this too is subject to individual interpretation. A definition of what the standards apply to, in terms of scope, is perhaps more important than the individual SARs. As such, I suggest that this scope needs to be developed through the SAR process. This needs to be addressed in a global fashion rather than relying on the development of a different scope for each SAR. 3. The proposed SARs deviate from the white paper direction to focus on reliability and delve into areas which are potentially outside of their scope such as; equipment damage, data sharing, procedures and studies. To the extent that these areas are performance related, the need is understood. However the development of past standards has shown that these areas often become part of a standard when they are really only one method of how a given level of performance can be achieved. 4. The 'High Level Map of Old Doc's to new Doc's' proposed by SAC (attached at the end of this package) provides a mapping of existing NERC planning and operating standards into the proposed new SARs. Each of the broad areas defined by the existing standards must be judged carefully against the 'White Paper' principles before even being included in the mapping. It is our belief that many will not pass this test. 5. The language of the proposed set of SARs struggle (understandably) to recognize the industry changes facing open electricity markets. Often they reflect a historic utility perspective including distinctions between 'planning' and 'operating' and emphasis on elements of 'pro forma' tariffs, which may no longer be relevant. To the maximum extent possible, the SARs must be developed to be independent of organizational and regulatory structures as well as respecting Regional and international differences. In our view, performance based standards are the best way to recognize this diversity. 			
We are very supportive of the goals NERC has set and would be glad to discuss further or participate more directly in their development.			
Is there a reliability-related need for an Organization Standard to be developed on this topic?			

Yes No

Yes No The scope of the SAR is fine as it is

The scope of the SAR should be expanded to include:

The scope of the SAR should be reduced to eliminate:

The SAR must be rigorously tested against the White Paper requirements to specify what performance must be achieved rather than how to achieve that performance. For example, in what way is a standard for 'planning the transmission systems' a performance standard? Wouldn't such a standard be considered one means of determining whether a performance standard based on system behaviour (both present and future) is met?

Other comments: The Standard description implies that there should be a single transmission expansion plan. It reads as if there is or must be a single coordinated and minimum cost plan (same theme in the Planning Authority proposal currently being circulated for comment). In a market environment, there may be a need for multiple plans since the viability and timing of various generator projects (and the system enhancements that may be required for deliverability of their output) will be dictated by commercial rather than system adequacy considerations. Similarly the timing of merchant transmission projects will reflect commercial rather than system security considerations

A minimum set of criteria for assessing the acceptability of plans is needed. The NPCC A-2 (see www.npcc.org) document covers the aspects of ensuring against significant (disagree with the use of "extreme" in the SAR), adverse impacts over a wide area. Market systems also need criteria to determine when to initiate or order plans, or trigger some regulatory backstop if expansion plans are deemed to be insufficient to meet needs. (Must also define what minimum need is).

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: The promulgation for comment of these SARs is premature. The industry "standard making process" is in a transition phase and it is overly burdensome to devote resources at this time. Once legislation or FERC firmly determines which entity(ies) is responsible for standards it will make sense to move forward with said entity. Even if NERC wants to cover reliability standards, almost all standards have a reliability and commercial impact; thereby, necessitating developing a single process that incorporates both commercial and reliability aspects of standards development. The current NERC process risks being changed soon, discounts commercial aspects, and is not part of a finalized overall industry process. Waiting a short while to move forward on a new standards setting process is acceptable and prudent given that NERC standards are currently in place and the industry can continue to use these standards until the new process and standards setting organization(s) are firmly set.</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: The promulgation for comment of these SARs is premature. <p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing:</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: The IOS Subcommittee appreciates the opportunity of submitting comments on the ten SAR's posted by NERC. The IOS Subcommittee found the white paper most instructive in explaining the intent of this initial posting. Generally, the SAR's posted outline the topics for a reasonable first set of organization standards. Since much work is still to be done in developing the details of the SAR's and the related organization standards, a definitive statement on the comprehensive nature of these SAR's is premature at this point. The IOS Subcommittee does note that interconnected operations services are important components of several of the SAR's. NERC's IOS work, summarized in the IOS Reference Document in the NERC Operating Manual, has been substantive in identifying the minimum necessary components of interconnected operations services. Addressing more than simply the need to balance energy, the IOS work stresses the importance of responsive capabilities and controls necessary to achieve reliable bulk electric operation. The IOS Subcommittee recommends that the drafting of the proposed standards considers the IOS Reference Document and that IOS expertise be considered an essential competency of the standard drafting team.</p> <p>In its discussion of these SAR's, the IOS Subcommittee identified three fundamental policy issues needing resolution prior to detailed work on development of these standards. First, the SAR's generally propose that the organization standards would apply to Service Functions contained in the Reliability Model, and they do not propose addressing the role of generators, loads, and others in provision and delivery of IOS's. The SAR's implicitly assume that the roles of others will be addressed through contracts. While the IOS Subcommittee does not necessarily disagree with this assumption (no consensus has been reached either way), there is a need to further explore the potential applicability of aspects of the proposed standard to others. This issue requires further debate and may serve as a critical precedent for the scope of other Organization Standards. Second, the "Assess Transmission Future Needs and Develop Transmission Plans" SAR proposes a standard to develop plans. None of the SAR's identifies who has the obligation to implement the plan. A plan without assignment or accountability for implementation is likely to provide no fruitful results. Third, the proposed standards and associated measures and criteria should not be any more restrictive than is necessary for a reliable bulk electric system. Market mechanisms for the provision of IOS should not be unnecessarily constrained. Market design is evolving rapidly, including for example, the ability to provide real time balancing services through bid-based mechanisms.</p> <p>The IOS Subcommittee offers its assistance to the Standards Requestor(s) as further work is invested in development of these organization standards.</p>

Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid? <input checked="" type="checkbox"/> Yes <input type="checkbox"/> No	
Is there a reliability-related need for an Organization Standard to be developed on this topic? <input type="checkbox"/> Yes <input checked="" type="checkbox"/> No <input type="checkbox"/> Yes <input type="checkbox"/> No The scope of the SAR is fine as it is <input type="checkbox"/> The scope of the SAR should be expanded to include: <input type="checkbox"/> The scope of the SAR should be reduced to eliminate:	
Other comments: This is an ongoing function that will be coordinated by RTOs with transmission owners and market participants. Every RTO will have or already has a planning protocol on how long term transmission plans are developed. A standard is not needed to make this function occur. For those entities not in an RTO, a similar process will exist to develop long term transmission plans.

<p>This SAR and the other posted SARs provide an appropriate framework for transitioning existing NERC Operating Policies and Planning Standards into new, NERC Organization Standards. Multiple compliance measures may be defined and developed for each of the eleven proposed Organization Standards. The Organization Standards and related compliance measures should focus on what functions must be performed for reliability, on who is responsible for each compliance measure for each required function and not, on how the compliance measure is achieved. The compliance measure must be measurable or demonstrable to ensure compliance.</p> <p>Sound planning is the foundation for a reliable transmission system. Therefore a standard for defining transmission planning requirements is appropriate.</p> <p>ERCOT believes the following issues should be considered in the development of this standard:</p> <ul style="list-style-type: none"> · The assessment leading to a transmission plan may be the most important aspect of this standard. Operational challenges must be identified, coordinated and remedial action plans made. Facility solutions usually require a longer time frame than the operating requirements allow. · Incorporate a reasonable planning horizon - Sound planning must be based on reasonably accurate forecasts of future load and generation patterns. In the new competitive generation markets it is not possible to perform meaningful forecasts more than five years out. Attempting to do so is not a good use of scarce resources. · Allowance of Remedial Action Plans (RAP) and Special Protection Schemes (SPS)– Major transmission construction that may be the preferred long-term answer to transmission reliability usually has a long lead-time. There should be provisions for the interim use of RAP and SPS in meeting the planning standard. · Recognition of Regional differences - All standards should make allowance for reasonable differing regional requirements. Requirements may vary due to differences in climate, predominate generation type, transmission design standards, availability of interruptible load and market rules. · FACTS devices are emerging as feasible solutions to transmission improvements. They should be considered in the development of standards for transmission planning and facility ratings (may include in SAR ID# FACILITY_RATINGS_01_01 as well).

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid? <input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: The new Organizational Standards must include the “How’s” as well as the “What’s” to just maintain the current level of reliability for the electric transmission system. The current NERC Planning Standards and Operating Policies, in general, document the body of good utility practice that provides that currently level of reliability seen in North America. If only the Standards (“What’s”) were published without the Measures (“How’s”) the new document will be woefully inadequate. The planning, design, construction, operation and maintenance of the electric transmission system are a very refined process of applied scientific principles and technology. The current proposed Organizational Standards create a level of ambiguity that will not adequately ensure the reliability of the grid is maintained at the levels seen today. Southern Company suggests that NERC consider withdrawing the entire proposed set of standards and reconsider its process for developing reliability standards. When posting standards for comment, NERC should consider a longer comment period. Thirty days is too short due to the amount of corporate coordination and information gathering required to submit meaningful responses. With respect to the scope of reliability standards, the development of all reliability standards should be within the general context of ensuring that the grid is protected from uncontrolled or cascading interruption of network operation. None of the proposed SAR’s fully addresses these basic operational requirements, although certain aspects of these requirements are contained within some of the SAR’s. Therefore, it is recommended that NERC prepare an initial standard that establishes the minimum reliability requirements needed to prevent severe adverse events from occurring on our transmission system, i.e. uncontrolled or cascading interruption of network operation. This pivotal standard - call it “MINIMAL OPERATIONAL REQUIREMENTS” - would address such basic reliability considerations such as</p> <ul style="list-style-type: none"> • No operator should knowingly operate in a manner that inappropriately affects the reliability of another entity • No operator should allow operation of the system in such a manner that inappropriately risks cascading outage of the network or violates an operating security limit. • No operator should allow operations that violate safety standards established by the National Electric Safety Code, ANSI Standards, IEEE, etc.... • No operator should allow operations outside established equipment ratings • Etc. <p>These may or may not represent the appropriate set of minimal reliability considerations, and are offered for illustrative purposes only. Once this pivotal standard has been established and fully vetted, all future SAR’s can be developed within the context of these basic requirements. If it were deemed necessary to increase or adjust these pre-established minimum levels, the pending adjustments would need to be fully vetted in both the commercial and the reliability forums.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic? <input checked="" type="checkbox"/> Yes <input type="checkbox"/> No <input type="checkbox"/> Yes <input checked="" type="checkbox"/> No the scope of the SAR is fine as it is <input checked="" type="checkbox"/> The scope of the SAR should be expanded to include: The scope of this SAR is poorly written and does not adequately represent or convey the transmission planning functional responsibilities. A better way to phrase the purpose could be: To establish a standard for evaluating the performance of the transmission system to ensure that appropriate levels of functionality and reliability are achieved in both the short-term and long-term time frames. <input type="checkbox"/> The scope of the SAR should be reduced to eliminate: Other comments: The “Brief Description”, once again, is poorly written and does not represent transmission planning in general. The I.A. Planning Standard is a very functional standard with the exception of S3.M3 and should be</p>	

followed very closely as a template to the developing the scope of this SAR.

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: Application criteria for SPS (or Remedial Action Schemes) should be included. SPS, thought may be considered as some form of protection and control measure, is applied for many different purposes which may be systems related and not necessary equipment protection related. Clear criteria are needed for consistent application of SPS (RAS) and when SPS (RAS) could be considered as an alternative to mitigate for system deficiencies. Planning criteria need to provide guidance on when SPS should be applied as permanent measures and when it should be applied as temporary measures to mitigate potential system problems. Special Protection Schemes, Protection Schemes and Control Schemes should all be treated separately.</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input checked="" type="checkbox"/> Yes <input type="checkbox"/> No</p> <p><input type="checkbox"/> Yes <input type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p>1) Planning criteria should be expanded to include maintainability of the system. Simple mitigation measures such as removing equipment out of service during lightly loaded and off-peak hours, to make system adjustments and to allow equipment protection against high voltage conditions may not be considered practical since it may create N-1 operating conditions. Also, possible overall system deficiencies for interconnected systems may not allow such prudent practices such as removing equipment from service.</p> <p>2) Establish a separate SAR for implementation of various types of SPS - Identify criteria for application of each type such as: Overload mitigation, Adaptive overload mitigation schemes, UFLS, UVLS, stability related schemes, etc.</p> <p>3) Develop a plan to address operating issues for interconnected grids systems where SPS is used systematically to mitigate against many different types of system deficiencies within a Region, operating in a coordinated manner with multiple mitigation measures simultaneously operating in parallel creates increased potential for cascading outages following an un-planned outage.</p>

<p>Does this set of Proposed Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American grid?</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No</p> <p>If you believe there are some performance areas not covered with the proposed set of Organization Standards, tell us what is missing: There is inadequate detail provided to allow a determination of whether the proposed set of Organization Standards cover the scope of performance needed to ensure reliability of the interconnected North American Grid. The answer to this question will depend upon the specifics included in each SAR. Detailed SARs must be developed and recirculated before any work begins on development of detailed Organization Standards. These SAR's should be specific about the WHAT of what is the reliability requirement and WHO is obligated to comply (but does not necessarily need detail as to HOW and should not set commercial practices as to HOW to comply) .</p> <p>Illinois Power suggests the following approach to developing an adequately detailed SAR:</p> <p>1) For each Function, determine what are the necessary standards to which the provider of that function should be held to in order to ensure reliability. This should not be a wholesale transfer of existing NERC Operating Procedures and Planning Standards into Organization Standards.</p> <p>2) Consideration should be given to having Standards that apply clearly for each Function rather than multiple Functions being addressed within topical Standards. In that way a Balancing Authority, for example, would only need to be concerned with one Standard, not sorting through multiple standards to figure out what applies to them. Much easier for training their people, keeping track of changes, etc.</p> <p>3) Each SAR should clearly identify specific and measurable requirements. This aspect is key and should not be left to the later development work, nor should the Standard Writers have authority to expand the specific, measurable reliability requirements without coming through the SAR process. Should NERC decide to proceed based upon the information submitted for comment, Illinois Power has provided specific comments on each SAR.</p> <p>If you believe there are some performance areas that are included in the proposed set of Organization Standards but are not needed, tell us what you believe is not needed: See above</p>	
<p>Is there a reliability-related need for an Organization Standard to be developed on this topic?</p> <p><input type="checkbox"/> Yes <input type="checkbox"/> No THE INTENT OF THIS STANDARD IS UNCLEAR SUCH THAT WE CANNOT DETERMINE IF THERE IS A NEED</p> <p><input type="checkbox"/> Yes <input checked="" type="checkbox"/> No The scope of the SAR is fine as it is</p> <p><input type="checkbox"/> The scope of the SAR should be expanded to include:</p> <p><input checked="" type="checkbox"/> The scope of the SAR should be reduced to eliminate: Reliability Authorities: In reviewing a Reliability Authorities responsibilities, it does not appear to Illinois Power that the RA has any responsibility to assess FUTURE needs or develop FUTURE plans, and therefore would not be subject to this Standard</p> <p>Other comments: There is inadequate detail in the SAR to determine if the scope of the SAR is appropriate and adequate. A standard in this area should focus on the minimum frequency of assessment and the definition of normal, abnormal, and extreme conditions that must be studied. The creation of a plan should not be a measurable standard as implied in this SAR. Nor should the Standard require specific operating, construction, or market solutions. It should only define the reliability requirements</p>

<input type="checkbox"/> The scope of the SAR should be reduced to eliminate:	
Other comments: These comments apply to the complete set of Proposed Organization Standards. Among the set of SARs, the references to "Reliability Function(s) That Would Need to Comply With This Standard" is not consistent. Ensure the "Function Definitions" from The NERC Functional Model are used consistently throughout. All of the "Reliability Principle(s)" should be listed first to ensure the reader knows what all of them are. In the SAR form they are referred to as "Reliability and Market Interface Principles". It appears that the term "interconnected bulk electric systems" is not consistently used.	
The Brief Description refers to "or other components to address these conditions." The vagueness is problematic as was discovered in the crafting of the original NERC Planning Standards.

Assess Transmission Future Needs and Develop Transmission Plans SAR

**Consideration of Industry Comments on SAR Version 1
(SAR Originally Posted for Comment 4/02/02 – 5/03/02)**

Background:

Version 1 of the “**Assess Transmission Future Needs and Develop Transmission Plans**” SAR was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for this SAR?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be reduced to eliminate.....
- The scope of the SAR should be expanded to include.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

This document contains the DT responses to the first set of comments on the original SAR. Because almost 2 years have elapsed since the comments were collected, some have become dated and no longer apply to the present situation. Thus, the DT has not addressed each and every comment, but rather only those that are still timely and represent a general consensus from industry.

Please note that the original comments from industry respondents are shown as underlined text, while the SAR DT responses are shown in **yellow highlight**.

Question: “Is there a Reliability-Related Need for this SAR?”

Development of this SAR is not needed or is premature.

Industry comments were overwhelmingly in favor of a standard on transmission assessment and planning, so the SAR DT feels we should proceed with the preparation of a final SAR to be posted for industry comment.

Question: “Scope of this SAR Should be Reduced to Eliminate”

Standard should not go beyond assessment & planning of the bulk transmission system.

We agree. The DT feels that this SAR as presently written does not go beyond assessment and planning of the bulk transmission system.

Standard should not apply to intrastate systems.

These standards are being drafted to apply to ALL North American bulk electric systems.

Market solutions are outside NERC’s scope with respect to development of reliability policies.

Agreed. The present SAR does not require transmission plans to facilitate market operation -- instead, the emphasis is on ensuring reliability.

Definition of “what” core reliability standards are needed is encouraged. However, “how” they are achieved and implemented should not be included at this time, until there is clarity on SMD & RTO formation, and NERC/NAESB interface is defined.

We agree. Industry responses to postings of other SARs and standards indicate that it is widely felt that NERC standards should concentrate on “what” the requirements are, not “how” to achieve them.

SAR should only address creation of Planning Standards. Plan Development is a compliance issue.

The Standard will not tell people “how” to achieve the solutions, but only require that they have a Plan. This is in accordance with the Functional Model, which requires that each Planning Authority have a documented Plan to address inadequacies identified in a transmission needs assessment.

SAR should only define the reliability requirements, not specific solutions.

Agreed.

Eliminate the function relating to “assessing” transmission performance. Only “plan” future transmission expansion.

Assessment of the transmission system is needed to identify anticipated deficiencies that proper planning will correct. Thus, the SAR DT feels that both “assessment” and “planning” are essential components of this SAR.

Standard should only apply to the long-term planning function. Should be a parallel standard for operational planning.

We agree. The standard will only address long term planning, which is defined in the Functional Model as 1 year and beyond.

Standard must not become a mandate for all to use the same load flow model.

Agreed.

Question: “*Scope of this SAR Should be Expanded to Include*”

Scope should be expanded to include generation as well.

The SAR DT understands this requirement to “include” generation to mean developing transmission plans that include (as inputs to the transmission adequacy assessment) resources, adequacy plans and load forecasts of LSE’s . According to the Functional Model, the Planning Authority must develop an integrated plan from both Transmission Planners and Resource Planners. We agree generation should be included; however, we do not believe that there should be a single standard that integrates resource adequacy planning and transmission adequacy planning. This standard should address only transmission adequacy planning. Separate RA standards may be developed, applicable to different entities; e.g., transmission standards for TOs, resource standards for LSEs .

NERC should guard against establishing a one-dimensional standard that fails to take into account all dimensions that guide the planning process.

Agreed.

SAR should include a requirement to plan the system so that it can be operated within operating limits.

The SAR DT believes that complying with a properly-designed planning standard will result in a system that can be operated within operating limits.

Scope should include planning associated with IPPs

See our response to the comment above that the “scope should be expanded to include generation as well”.

NERC should ensure that the standards defined include a definition of how the planning model is created.

The SAR DT has attempted to address this issue in the proposed SAR.

Standard should be specific and measurable and define what “normal”, “extreme”, and “abnormal” system conditions are.

Agreed. The DT has deleted these terms from the SAR and instead has included a requirement that the standard use the contingency events identified in Table 1 of existing Planning Standard I.A.

Minimum set of criteria for assessing acceptability of plans is needed.

The SAR DT believes the proposed SAR establishes minimum system performance standards, but does not direct how to meet those standards. For a Plan to be acceptable, anticipated system performance under the Plan must meet the minimum criteria established by the standard.

May be a need for multiple expansion plans because of timing of generator projects that are dictated by commercial rather than system adequacy considerations.

The SAR DT does not envision that the standard will address commercial or market issues. However, the standard will require documentation and disclosure of generation assumptions used to develop the Transmission Plan.

Must define what minimum need is. Some regulatory backstop is needed if expansion plans are deemed insufficient to meet needs.

The DT feels that the SAR as written will result in a standard that defines the minimum need.

SAR should identify who has obligation to implement transmission plans.

The Functional Model identifies which functions have the responsibility to implement transmission plans. The SAR DT (in the Comment Form posted with Version 2 of the SAR) has asked for industry guidance on the monitoring of implementation plans.

Must use a reasonable planning horizon (less than or equal to 5 years).

The DT believes that the SAR as written will result in a standard that requires the use of a reasonable planning horizon.

Provision for interim use of Remedial Action Plans (RAP) & Special Protection Schemes (SPS) is needed.

The SAR DT feels that the standard will neither require nor preclude the use of RAP or SPS for either interim or permanent use to meet the reliability criteria contained in the standard.

Regional differences should be recognized.

Agreed. The SAR DT has asked for industry input to identify such differences. See the Comment Form posted with the SAR – V2.

Requirement to provide assessment at all demand levels should be added.

The SAR DT has developed language to consider the variability of load in the development of the standard.

Responsibility for assessing and defining adequate operating reserves and reactive support should be added.

The SAR DT believes operating reserves is an operational issue that should be addressed by operating standards. However, voltage support and reactive power will be addressed in this standard.

Planning criteria should be expanded to include maintainability of system.

The SAR DT has asked for industry input on this issue. Refer to the Comment Form posted with the SAR – V2.

When studies indicate that the system may not meet performance requirements, plans should be developed to address the situation and studies should demonstrate that implemented plans meet requirements.

We agree.

Core standard for reliability should be specific & measurable.

Agreed.

“Miscellaneous Comments”

Technical specifications should ensure that they do not prohibit worthwhile commercial negotiations or commercial activity.

Agreed.

Must have coordination with operating procedures and protocols of RTOs.

The standard will be applicable to all functional responsibilities included in the Functional Model.

Must be close coordination with NAESB and RTOs to meet both reliability objectives and commercial needs.

The standard will define reliability criteria without precluding or dictating viable commercial solutions.

Measuring for compliance is extremely difficult. It is also difficult to determine if events will result in “cascading outages”.

We believe the standard will clarify and explicitly state the requirements for compliance. Agreed that a clearer definition of “cascading outages” is needed, and the definition is being developed.

SAR will not accomplish its intent without credible models from which to do analysis.

Agreed.

SAR seems large – divide it up?

The SAR does cover a large scope, but the DT feels that dividing the SAR and standard is premature at this point.

Scope of SAR is poorly written. It does not convey transmission planning responsibilities.

Scope is being revised to add more details and become clearer.

Separate SAR should be established for implementation of SPS. Develop plans to address operational issues for interconnected grids where SPS is needed to mitigate against system deficiencies.

There is a separate SAR that addresses Protection Systems. To the extent that SPS affects transmission assessment and planning, some aspects of SPS may be addressed in this SAR.

SAR does not set standard, but tries to assign responsibility for setting standard.
As envisioned, this SAR will address BOTH the standard and the responsibility.

END OF INDUSTRY COMMENTS/DT RESPONSES FOR SAR – V1

Standard Authorization Request Form

Title of Proposed Standard	Assess Transmission Future Needs and Develop Transmission Plans
Request Date	May 01, 2004

SAR Requestor Information	SAR Type (Put an 'x' in front of one of these selections)	
Name Paul Rocha	<input checked="" type="checkbox"/>	New Standard
Primary Contact Paul Rocha	<input type="checkbox"/>	Revision to existing Standard
Telephone (713) 207-2768 Fax	<input type="checkbox"/>	Withdrawal of existing Standard
E-mail paul.rocha@centerpointenergy.com	<input type="checkbox"/>	Urgent Action

Purpose/Industry Need (Provide one or two sentences)

To establish a standard for assessing and planning the transmission systems in North America. The transmission system must be assessed and planned to ensure that it performs its intended functions in providing reliable delivery of power for the future needs of customers.

Reliability Functions

The Standard will Apply to the Following Functions (Check box for each one that applies by double clicking the grey boxes.)		
<input checked="" type="checkbox"/>	Reliability Authority	Ensures the reliability of the bulk transmission system within its Reliability Authority area. This is the highest reliability authority.
<input type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within its metered boundary and supports system frequency in real time
<input type="checkbox"/>	Interchange Authority	Authorizes valid and balanced Interchange Schedules
<input checked="" type="checkbox"/>	Planning Authority	Plans the bulk electric system
<input type="checkbox"/>	Resource Planner	Develops a long-term (>1year) plan for the resource adequacy of specific loads within a Planning Authority area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a long-term (>1 year) plan for the reliability of transmission systems within its portion of the Planning Authority area.
<input type="checkbox"/>	Transmission Service Provider	Provides transmission services to qualified market participants under applicable transmission service agreements
<input checked="" type="checkbox"/>	Transmission Owner	Owns transmission facilities
<input type="checkbox"/>	Transmission Operator	Operates and maintains the transmission facilities, and executes switching orders
<input type="checkbox"/>	Distribution Provider	Provides and operates the “wires” between the transmission system and the customer
<input type="checkbox"/>	Generator Owner	Owns and maintains generation unit(s)
<input type="checkbox"/>	Generator Operator	Operates generation unit(s) and performs the functions of supplying energy and Interconnected Operations Services
<input type="checkbox"/>	Purchasing-Selling Entity	The function of purchasing or selling energy, capacity and all necessary Interconnected Operations Services as required
<input type="checkbox"/>	Market Operator	Integrates energy, capacity, balancing, and transmission resources to achieve an economic, reliability-constrained dispatch.
<input type="checkbox"/>	Load-Serving Entity	Secures energy and transmission (and related generation services) to serve the end user

Reliability and Market Interface Principles

Applicable Reliability Principles (Check boxes for all that apply by double clicking the grey boxes.)	
<input checked="" type="checkbox"/>	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input type="checkbox"/>	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
<input type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
<input type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified and have the responsibility and authority to implement actions.
<input type="checkbox"/>	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
Does the proposed Standard comply with all of the following Market Interface Principles? (Select 'yes' or 'no' from the drop-down box by double clicking the grey area.)	
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes	
2. An Organization Standard shall not give any market participant an unfair competitive advantage. Yes	
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes	
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes	
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes	

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.)

The Standard shall establish requirements for assessing the performance of planned bulk electric transmission systems and the requirements for documenting a plan to remedy any inadequacies identified in the process of conducting such assessments.

The scope of such assessments and plans is for a planning horizon of one year or more. The scope *does not* include the operating horizon less than one year. While the planning horizon is intended to provide for facility additions, there is no intent to exclude appropriate operating procedures from the transmission plan.

The planning horizon must be long enough to permit timely implementation of viable solutions to remedy the potential inadequacies found. Assessments should cover a planning horizon of at least 5 years. The horizon may be longer than 5 years, based on regulatory or legislative requirements, or on the judgment of the Transmission Planner or Planning Authority.

The Standard shall identify reliability requirements, but shall not specify *how* to achieve such requirements. These requirements shall apply to Transmission Planners and to Planning Authorities.

The applicable portions of the following existing NERC Planning Standards will be used as the starting point in drafting these requirements:

- I.A Transmission Systems
- I.B Reliability Assessment
- I.D Voltage Support & Reactive Power
- II.A System Data
- II.D Actual and Forecast Demands

The Standard shall require that system models be developed, maintained and shared in a manner consistent with the Functional Model. Included will be requirements that each Planning Authority and Transmission Planner document and disclose the methodology used for incorporating planned generation assets in the model, as well as how such generation is dispatched. While methodologies and assumptions must be documented, the Standard will *not* prescribe specific tools to be used in the performance assessment of the planned systems.

The Standard will identify the various planning functions that are responsible for compliance with the standard criteria. The assignment of compliance responsibility will be consistent with the Functional Model.

This Standard will *not* include requirements for:

- Resource Planning (i.e., assessing or ensuring the availability of adequate generation resources to serve load).
- Planning generation additions to remedy any generation resource inadequacies.
- Mitigation plans to relieve congestion due to economy transfers of generation resources.

However, the Standard should neither preclude nor require the consideration of generation or load (demand side management) or operating procedures as alternatives to transmission reinforcement/reconfiguration when developing solutions to potential transmission inadequacies.

While the Standard should start from and closely align with the existing Planning Standards I.A, .B, .D, II.A,.D, the system conditions to be studied or assessed may need to be better defined or clarified. For example, the Standard should clarify that the requirement to assess the performance at **all** demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with regionally-defined criteria.

Other examples of areas that should be considered for clarification in the Standard include:

- The Standard should provide a clearer definition of “cascading outages”.*

*Existing Planning Standard I.A definition: “Cascading is the uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread service interruption which cannot be restrained from sequentially spreading beyond an area predetermined by appropriate studies”

- The Standard should take into account the variability of load due to factors such as weather and time of day.
- The Standard should allow for the development and use of probabilistic planning methods. The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A.. There should be NERC approval of acceptable levels of risk.
- Existing Planning Standard S1, S2, S3, S4 and Table I.A Category A, B, C, D should be clarified on the issue of how a planned outage should be used in an assessment.
- Performance requirements for Category C events shall be re-evaluated. For example, for certain Category C events, such as #2, #3 and #9 events, consider removing references to “Applicable Ratings” to clarify that the performance requirement is “No Cascading Outages are Allowed”.
- The Standard should include requirements to ensure that the maximum available short circuit current is within the ratings of transmission facilities.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Multiple contingencies have lower and varying probabilities of occurrence.

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- Yes (consider planned outages in all Categories A through D).
 Yes (consider planned outages in some Categories only).

Please specify which Categories: B and some C.

- No
 Comments:

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

WECC has asked the NERC PC for waivers for some of the Category C requirements.

6. Do you have any other comments on the SAR?

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: Allegheny Power feels that it is practical to consider planned outages in categories A and B.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments: Under “Detailed Description” the second and third paragraphs are unclear and appear to be conflicting. The first of those paragraphs specifies that the “scope of such assessments and plans is for a planning horizon of one year or more”. The second of those paragraphs specifies, “Assessments should cover a planning horizon of at least 5 years”. This appears to be a conflict. It may be that the term “planning horizon” is being used differently in these two paragraphs. It is unclear to us what is the intention of the first of those two paragraphs is.

Also under “Detailed Description on page SAR-5, the paragraph starting “While the Standard should start from...” has a problem with it’s second sentence. The sentence “For example...” does really apply to the first sentence. We recommend that this paragraph be changed as follows:

While the Standard should start from and closely align with the existing Planning Standards I.A, .B, .D, II.A,.D, the system conditions to be studied or assessed may need to be better defined or clarified.

Examples of areas that should be considered for clarification in the Standard include:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

- The Standard should clarify that the requirement to assess the performance at all demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with regionally-defined criteria.
- The Standard should provide a clearer definition of “cascading outages”.*

And so on.

Also in that bulleted list, the existing 5th bullet item, “Performance requirements for Category C events shall be re-evaluated. For example, for certain Category C events , such as #2, #3 and #9 events, consider removing references to “Applicable Ratings” to clarify that the performance requirement is “no Cascading Outages are Allowed” doesn’t appear necessary. “No Cascading Outages” is already part of Table I for these events. Removing “Applicable Ratings” would not add to the clarity.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 1 and May 31, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

MidAmerican Energy believes the interconnected transmission system should be planned, designed, and constructed to withstand high probability events and to withstand low probability events with significant negative consequences. MidAmerican believes it is a waste of the ratepayers’ money to plan, design, and construct the interconnected transmission system for low probability events without significant negative consequences.

MidAmerican Energy would reclassify certain low probability events such as Category C1 events, C2 events, certain Category C3 events (two transformers, transmission circuit plus a transformer, two transmission circuits, DC line plus a transformer, DC line plus a transmission circuit, and two DC lines), C6 events, C7 events, C8 events, and C9 events to a new category between C and D with performance characteristics between that of the present Categories C and D. MidAmerican Energy would require that the interconnected transmission system be planned, designed, and constructed to protect for instability, cascading, and uncontrolled separation for the low probability events in the new sub-category.

MidAmerican Energy believes the following information supports this new reclassification by demonstrating that the events that MidAmerican recommends for reclassification are the low probability Category C events. MidAmerican recognizes that published outage data are subject to interpretation, potential inaccuracy, and change through time; however, MidAmerican believes that MidAmerican operating experience with transmission element outages supports the statistical summary provided in the following table.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

The approach that results in the most appropriate transmission system design is the one recommended by MidAmerican Energy. Improvements should be planned for those Category C events that are high probability events regardless of the consequences. Planners should also review all Category C events for instability, cascading, and uncontrolled separation. Improvements should be planned for those Category C events (both high probability and low probability events) which have significant consequences, that is, that result in instability, cascading, and uncontrolled separation. It is MidAmerican's belief that the intent of the drafting team that originally developed the existing NERC Planning Standards was to require the NERC member to plan to protect for instability, cascading, and uncontrolled separation for Category C events.

MidAmerican believes reclassifying less likely Category C events as Category D events will result in planners ignoring low-probability contingencies that result in significant consequences: cascading, uncontrolled separation, and instability.

MidAmerican believes that allowing for “good cause exceptions” is also not the preferable approach. MidAmerican believes that the events listed by MidAmerican for reclassification are much less likely than the other Category C events generally throughout NERC. This means that these events should be reclassified in general throughout NERC and not just in certain “good cause exceptions”. (Although, it should be noted that MidAmerican does support regional differences where appropriate.) Besides, there are issues associated with the development and utilization of a process for approving “good cause exceptions”.

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments: MidAmerican Energy believes that this standard should not include requirements for reporting on the progress or status of implementing the plans developed in accordance with this standard. There are too many conditions beyond the control of the NERC member for this to be a part of a standard requiring compliance review. Complex environmental, regulatory, and political issues prevent many transmission facilities from being constructed or being constructed in a scheduled manner. The Not-In-My-Back-Yard philosophy has hit even the rural areas so that there is no part of the NERC area where a NERC member can confidently predict completion of transmission system improvements in plans. Further, conditions can change even during a year to such an extent that compliance review for implementation from one year to the next is problematic. Further, regulatory oversight provides for appropriate review of plan implementation anyway. MidAmerican urges that the SAR drafting team not pursue this well-meaning but problematic approach.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments:

Planned Outages can be scheduled and analyzed in advance in the operating horizon (less than one year). Therefore, it should not be necessary to require that "systems must be capable of meeting Category C requirements while accommodating the planned outage of any bulk electric equipment..." Planned outages should be studied in advance by the requesting control area and be reviewed by the governing Reliability Coordinator to determine if overloads could occur. If studies show that overloads could occur, the planned outage should be deferred or operating guides prepared which would be used in the event a contingency does occur.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

There is no need to plan or build facilities to meet Planning Standard 1.A when Planned Outages can be accommodated within the frame work of existing guidelines and procedures. Studies conducted for the operating horizon are not the subject of this standard.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

a. MidAmerican Energy urges the SAR drafting team to add Category C#1, #6, #7 and #8 events to the second from last paragraph in the SAR which describes considering removing references to “Applicable Ratings” to clarify the performance requirement for certain Category C events.

b. MidAmerican Energy urges the SAR drafting team to direct the Standard Drafting Team to remove references to “Applicable Ratings” from all events listed in the second to last paragraph because information is readily available which demonstrates that the listed events are much less likely than other Category C events.

c. MidAmerican Energy urges the SAR drafting team to add the following words to the third paragraph from the end to more clearly explain the SAR drafting team’s position with regard to planned outages:

“In particular, it is incorrect to have a requirement to exhaustively test for every contingency described in each category plus every conceivable planning outage.

Planned Outages can be scheduled and analyzed in advance in the operating horizon (less than one year). Therefore, it should not be necessary to require that "systems must be capable of meeting Category C requirements while accommodating the planned outage of any bulk electric equipment..." Planned outages should be studied in advance by the requesting control area and be reviewed by the governing Reliability Coordinator to determine if overloads could occur. If studies show that overloads could occur, the planned outage should be deferred or operating guides prepared which would be used in the event a contingency does occur.

There is no need to plan or build facilities to meet Planning Standard 1.A when Planned Outages can be accommodated within the frame work of existing guidelines and procedures. Studies conducted for the operating horizon are not the subject of this standard.

Therefore, the SAR drafting team directs the standard drafting team to delete the requirement for the prior planned outage from the standard given that known planned outages must be included in studies that are conducted during the operating horizon which are not the subject of this standard but which are required in accordance with NERC Standard 200, “Operate Within Interconnection Reliability Operating Limits Standard” and NERC Standard 600, “Determine Facility Ratings, Operating Limits, and Transfer Capabilities”.

d. MidAmerican Energy urges the SAR drafting team to include the following statement in the SAR:

“The Standard should clarify how breaker failure events (Category C2, C6, C7, C8, and C9 events) are to be considered given that operating a breaker with disconnects open or eliminating a breaker are technically acceptable mitigation schemes for such events. Such mitigation schemes actually result in less reliable system designs and system operating configurations. Thus including Applicable Ratings in the Standard for these lower probability breaker failure events can send the wrong reliability signals to NERC members.”

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

This paragraph reflects another reason why breaker failure events should be reclassified such that Applicable Ratings is no longer considered a requirement for these low probability events.

e. MidAmerican Energy urges the SAR drafting team to consider not reclassifying any of the Category C events to Category D but instead deleting the Applicable Rating requirements from the lower probability Category C events. MidAmerican believes that the performance requirements for lower probability Category C events should be to protect for cascading, instability, and uncontrolled separation. It is MidAmerican's belief that this was the intent of the drafting team that originally developed the existing NERC Planning Standards.

f. MidAmerican Energy is concerned that the SAR does not provide for the coordination of the requirements of the planning standards in NERC Standard 500, “Assess Transmission Future Needs and Develop Transmission Plans”, with the NERC Operating Standards provided in NERC Standard 600, “Determine Facility Ratings, Operating Limits, and Transfer Capabilities.” The criteria that are proposed as a starting point for 500 in this SAR (events from Categories A through D) differ from the criteria that are included in the latest draft of NERC Standard 600 (Categories A and B). If these approaches are continued, then studies run for the operating horizon will differ significantly from studies run for the planning horizon. These differences in studies will carry over to the calculation of quantities used to offer transmission service, that is, Total Transfer Capacity and Available Transmission Capacity. If NERC does not coordinate these two standards, there will be a discontinuity in TTC and ATCs when the Planning Horizon begins and the Operating Horizon ends or from one day less than one year to one year. MidAmerican urges the SAR drafting team to consider this discontinuity and coordinate the SAR for 500 with the Standard that is being written for 600. If a discontinuity between criteria is allowed to continue in the SAR for Standard 500, the SAR drafting team should have a clear explanation for all market participants as to the reason for the discontinuity and how that should be dealt with by the elements of the NERC Functional Model.

g. In general, MidAmerican Energy supports the six bullets that the SAR drafting team has provided on page SAR-5 with the amendments and additions described above in our comments. These bullets add needed details to the SAR.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 1 and May 31, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments: The definition of applicable ratings needs to be clarified. The SAR DT should also indicate if it is feasible to have different applicable ratings for different categories of events.

The SAR DT should review the history of the original classification. This review should include all classes. If outage statistics are used to classify events, how many years of data are appropriate? If the data window is too small, the results will be skewed. Moreover, is it appropriate to use outage data for all these categories of events? Outage data over a long period of time may provide insight into equipment performance, but is it appropriate to reflect weather related contingency events – the data may not reflect the effect of a once in a 100 year storm?

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

MAPP would reclassify certain low probability events such as Category C1 events, C2 events, certain Category C3 events (two transformers, transmission circuit plus a transformer, two transmission circuits, DC line plus a transformer, DC line plus a transmission circuit, and two DC lines), C6 events, C7 events, C8 events, and C9 events to either a new category between C and D with performance characteristics between that of the present Categories C and D or to Category D. MAPP would require that the interconnected transmission system be planned, designed, and constructed to protect for instability, cascading, and uncontrolled separation for the low probability events in the new sub-category. Regions should develop procedures for determining that systems are properly protected for instability, cascading and uncontrolled separation.

MAPP believes the following information supports this new reclassification by demonstrating that the events that MAPP recommends for reclassification are the low probability Category C events. MAPP recognizes that published outage data are subject to interpretation, potential inaccuracy, and change through time; however, MAPP believes that MAPP operating experience with transmission element outages supports the statistical summary provided in the following table.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

345 kV Outage Data				
Contingency	Outage Rate, occ./year	Duration, hours	Probability	Relative Likelihood

tcmielnik@midamerican.com

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

If the events are low probability, then some should be considered for moving to Cat D.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Improvements should be planned for those Category C events that are high probability events regardless of the consequences. Planners should also review all Category C events for instability, cascading, and uncontrolled separation. Improvements should be planned for those Category C events (both high probability and low probability events) which have significant consequences, that is, that result in instability, cascading, and uncontrolled separation.

MAPP believes that allowing for “good cause exceptions” is not the preferable approach. MAPP believes that the events listed by MAPP for reclassification are much less likely than the other Category C events generally throughout NERC. This means that these events should be reclassified in general throughout NERC and not just in certain “good cause exceptions”. (Although, it should be noted that MAPP does support regional differences where appropriate.) Besides, there are issues associated with the development and utilization of a process for approving “good cause exceptions”.

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

Comments: Requirements for reporting on the progress or status of implementing the plans should be left to the regions and appropriate regulatory bodies. The MAPP Regional Transmission Committee currently has a regional planning process for compliance for implementing transmission plans.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments:

Planned Outages can be scheduled and analyzed in advance in the operating horizon (less than one year). Therefore, it should not be necessary to require that "systems must be capable of meeting Category C requirements while accommodating the planned outage of any bulk electric equipment..." Planned outages should be studied in advance by the requesting control area and be reviewed by the governing Reliability Coordinator to determine if overloads could occur. If studies show that overloads could occur, the planned outage should be deferred or operating guides prepared which would be used in the event a contingency does occur.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

a. MAPP urges the SAR drafting team clarify the meaning of the term "Applicable Ratings" and determine if it is possible to have different A/Rs for different categories.

b. MAPP urges the SAR drafting team to add words to the third paragraph from the end to more clearly explain the SAR drafting team's position with regard to prior planned outages.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

c. MAPP is concerned that the SAR does not provide for the coordination of the requirements of the planning standards in NERC Standard 500, “Assess Transmission Future Needs and Develop Transmission Plans”, with the NERC Operating Standards provided in NERC Standard 600, “Determine Facility Ratings, Operating Limits, and Transfer Capabilities.” The criteria that are proposed as a starting point for 500 in this SAR (events from Categories A through D) differ from the criteria that are included in the latest draft of NERC Standard 600 (Categories A and B). If these approaches are continued, then studies run for the operating horizon will differ significantly from studies run for the planning horizon. These differences in studies will carry over to the calculation of quantities used to offer transmission service, that is, Total Transfer Capacity and Available Transmission Capacity. If NERC does not coordinate these two standards, there will be a discontinuity in TTC and ATCs when the Planning Horizon begins and the Operating Horizon ends or from one day less than one year to one year. MAPP urges the SAR drafting team to consider this discontinuity and coordinate the SAR for 500 with the Standard that is being written for 600. If a discontinuity between criteria is allowed to continue in the SAR for Standard 500, the SAR drafting team should have a clear explanation for all market participants as to the reason for the discontinuity and how that should be dealt with by the elements of the NERC Functional Model.

d. MAPP notes that Standard 600, “Determine Facility Ratings, Operating Limits, and Transfer Capabilities” has been drafted to do away with the references to Categories A through D. The criteria are just listed in the standard. MAPP asks that the SAR drafting team require that the standard drafting team for Standard 500 also eliminate the category references to be consistent with the Standard 600 approach.

e. MAPP is concerned that the SAR does not limit manual or automatic readjustments for certain lower probability or low consequence events. MAPP urges that the SAR drafting team add additional provisions to require the drafting team to consider which manual and automatic readjustments are allowed and when in meeting the criteria that is included in the standards.

f. MAPP is concerned that there is no provision for recognizing the variability of generation in the SAR. MAPP asks the SAR drafting team add another bullet to the SAR which states, “The Standard should take into account the variability of generation due to factors such as weather and time of day.”

g. MAPP is concerned that there is no reference in the SAR to the need to handle firm contracts that may roll-over in the futures. Plans developed for the transmission system must recognize that the transmission system must have sufficient capacity to handle roll-overs. MAPP urges the SAR drafting team to include an appropriate description of the requirement for the plans with regard to roll-overs.

h. MAPP asks that the SAR drafting team add a bullet to the SAR that requires that the Standard drafting team to consider the development of reactive power margin and transfer power margin standards which expand beyond existing NERC Standard I.D.

i. In general, MAPP supports the six bullets that the SAR drafting team has provided on page SAR-5 with the amendments and additions described above in our comments. These bullets add needed details to the SAR.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes, but see comments below

No

Comments: Categories B, C and D should be renamed as follows –

Category B – High Probability Contingency Event

Category C – Medium Probability Contingency Event

Category D – Low Probability Contingency Event

The difference in the categories should NOT be stated in terms of how many elements are out of service, but rather should be stated in terms of the PROBABILITY of the initiating event that occurs. The difference in the categories is in the “stress” the system is allowed to experience and in the “fix” required. For B, a high probability event, stress should be low and the only fix allowed is system reinforcement. For D, a low probability event, severe system stress is allowed, and system reinforcement is not mandated. C is somewhere in between, a medium probability, with medium system stress permitted, and some loss of load and/or curtailment of transfers allowed in lieu of system reinforcement. Table I can then be simplified by removing the column labeled “Elements Out of Service”, because it is unnecessary and not relative. Actually, the columns labeled “Thermal Limits”, “Voltage Limits”, “System Stable” and “Cascading Outages” can be eliminated too, because they are the same for each Category A, B and C (but notes for each column should be retained).

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments: NONE OF THE ABOVE. Keep the three categories, but rename them as in 1.a. above. Adding an additional category would introduce too much confusion in planning the system. Assuming that the contingencies in B, C and D are already in their correct probability categories, no changes need to be made. If someone could prove that a contingency in B is Low Probability the same as the contingencies in D, that contingency could be moved.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments: Reporting should be on a “delay” basis. Known delays to the plan should be reported, along with the reason for the delay and use of alternate solutions.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan? **See answer to 2. Above.**

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: **Categories A and B, which are high probability and therefore could easily occur during a planned outage.**

No

Comments:

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

X Comments: The SERC PSS believes that Category C events are more likely to occur than Category D events and should require higher performance expectations.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

X Comments: The SERC PSS agrees that low consequence Category C events should be considered compliant. However, as we interpret Table I, a Category C event that results in low consequences (e.g. no cascading) is already considered compliant since entities can drop load or curtail firm transfers to return to applicable thermal or voltage ratings.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

X Comments: The SERC PSS agrees that the requirement to consider planned outages in addition to each Category A and B contingency remain part of this planning standard. The SERC PSS could not reach consensus on the requirement to consider planned outages in addition to each Category C and D contingency. However, the SERC PSS does agree that exhaustive testing for every contingency described in each category is not required. The I.A compliance templates state that they must “Be performed and evaluated only for those Category [B, C, and D] contingencies that would produce the more severe system results or impacts.”

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain. No

Comments:

6. Do you have any other comments on the SAR?

X Comments: The SERC PSS agrees that the Standard should provide a clearer definition of “cascading outages.” In addition the SERC PSS recommends that the Standard provide a clearer definition of what is meant by “system stable.”

The SERC PSS agrees that the Standard should not address resource planning, however the standard should include requirements for LSEs to provide forecast resource data required to develop power flow models as required in the current II.D standards. Accordingly, this standard should also apply to LSEs.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments: **Without a rigorous Probabilistic Risk Analysis, moving any of these events to a category D event is bad practice. All of the events have occurred at one time or another, especially circuit breaker and bus faults. Moving them to a category D essentially removes them from requiring action to mitigate/solve the impact on reliability.**

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

Comments: Developing plans without a follow up program is a waste of time and money. One of the most telling comments from the August Blackout report was that a number of the items were the same as in other blackouts.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan? When there is a significant change in the assumptions, the plan needs to be re-studied and revised as appropriate. The SAR must require such re-studies. Any plan is only as good as its assumptions. Whenever there is a significant change in the assumptions, the plan needs to be revised to account for the change. Having a plan that assumes there will be specific generation projects is worthless when those specific projects are changed, cancelled or if other generation retires.

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: Categories A through C should be considered. Category D does not require action so the analysis with outages does not add anything. Most planning software allows the use of scripts to run multiple analysis without intervention. The state of modern computers is such that the added testing is not significant. Also, for most systems, this type of analysis is performed to define which load levels and generation dispatch would allow the maintenance (the problem in reverse).

No

Comments:

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments: Each region has their own requirements.

6. Do you have any other comments on the SAR?

Comments:

Second Paragraph: Replace the second sentence with "The planning horizon is intended to provide for facility additions. Operating procedures shall not be used as a substitute for good system design and shall only be applicable during maintenance outages and while facilities are being constructed." (The original language would allow what was identified as the root cause of the Italian blackout. Namely, an operating procedure that had to be executed within 15 minutes. The operator had to call another area and ask for them to perform an operating procedure. The procedure was underway but

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

did not happen fast enough to avoid the next line to trip. Operating procedures should never be a long term substitute for constructing facilities needed to assure reliability.)

Third Paragraph: While some of the information about generation additions and load growth are considered reliable for five (5) years, a long-term study of approximately ten (10) years is necessary to identify global issues such as import limitations to a region that would require projects that have traditionally taken more than five (5) years. Suggest, “Assessments shall cover a detailed planning horizon consistent with available information but no less than five (5) years. The five year horizon shall include load growth, new internal and external firm generation, generation retirements/failures, uncontrollable loop flows, reliance on external generation (identify both firm and market), topology changes, and firm transactions. A longer term study using a variety of scenarios that are expected to cover the most likely long term activity, shall be conducted to identify projects that take longer than five years to implement.”

Fourth Paragraph: The standards should apply to transmission owners, transmission operators, transmission planners, anyone who is connecting facilities to the transmission system, control areas, and reliability coordinators.

Fifth Paragraph: Add the following after the bullets. “In addition to the above, the standard shall provide requirements on methodology of forecasting and normalizing load. This would include methods of determining the normalized load over a large geographic area with different weather patterns and norms. The “normalized” load should not be the load associated with the median weather over a summer or winter period but the load level that will provide sufficient reliability to supply all firm load obligations. Each region shall provide a definition as to what is sufficient reliability. The definition shall clearly define the risk that is being assumed in terms similar to the LOLE for lack of generation. In addition to the above two risk variables, a methodology shall be identified to quantify the risk of not being able to deliver the difference between the local load and generation. This is essentially the ability of the transmission system to respond to different generation dispatch patterns.”

Sixth Paragraph: Replace the last phrase in the last sentence with “while the standard will not prescribe specific tools, it shall identify methodologies to validate and procedures to operate the tools so that the identified outcomes from the analysis are not dependent on the tool or the way the tool was used or initialized.”

Under the section of “Other Examples ...”

3rd Bullet: Add a sentence after the first sentence “The probabilistic methodology shall not ignore specific cases that would result in significant load dump or cascading outages. Each region shall identify how to resolve such outages.” The last sentence “Acceptable levels of risk in terms of maximum consequential and programmatic load dump and maximum durations for the outages shall be defined.”

5th bullet: Clarify that the “applicable ratings” for multiple events should be consistent with supplying firm load and firm transactions until the outages are repaired or switching mitigates the overloads. For example, one applicable rating would be the short time rating of equipment that was stressed when a transformer failed. However, there must be a method of supplying the load pocket for the duration to repair/replace the transformer that does not involve long term rotating blackouts. Just achieving “no cascading outages” is not sufficient.

New section: The subject of assuring the generation is deliverable to the load should be added. This should not be vague but should be defined by a specific set of tests and the expected range of results. In doing these tests, reliance on capacity assigned to other regions should be limited to amounts identified and accepted by adjacent regions. For example, if a region is assuming it will have net purchases from adjacent regions, the other regions must show a net sale.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 1 and May 31, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

All category C outages that have a direct impact on serving load because of the system configuration (straight bus or tapped load) should be reclassified, including C-1, C-2, C-5, and C-9 to provide more latitude. For category C events, we should be more concerned that the system holds together and not that the local load may be at risk for these multiple contingency events.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice: Reclassify C-1,C-2, and C-9 to category D (less probable events).

C-3 (line and a generator combination) should be reclassified as category B event (more probable than other C-3 events. Also, why is a loss of a tower line with two circuits category C (C-5) while loss of a tower line with 3 circuits is category D (D-6), though a probability of loss of a tower line may be the same ? We may want to be consistent in categorizing the event – loss of a multi-circuit tower line.

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Yes

No

Comments: The requirement should not be onerous.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

(i) Annual update with a short note to document changes.

(ii) Smaller projects (cap bank addition, change of terminal equipment like switches, wavetraps, or CT) may be combined as a group in such reporting to avoid providing a long list of updates.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: (i) Is the issue planning the system or granting the outage? Local load may be exposed for granting a maintenance/construction outage, but the system should not be at risk.

(ii) If the system is planned with category C requirements, in most cases it should meet category A and B requirements during a planned outage. To meet requirements of categories A and B during planned outage should be adequate.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

A. We believe that for planning of robust transmission system, the Standard should include (1) some incremental transfer capability requirement in addition to what is “projected” or modeled in the base case, (2) a combination of a line and a generator outage should be included in category B.

B. Page SAR-4, Paragraph 2, last phrase states that “...there is no intent to exclude appropriate operating procedures...”. What is “appropriate”? Could generation redispatch be an appropriate operating procedure? If yes, what level of redispatch is appropriate?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

The standard should include definition of “appropriateness” of operating procedures so that they are developed and applied on an uniform and consistent basis.

- C. Page SAR-4, Paragraph 4: Should the requirements be applied to Transmission Owners also?
- D. Page SAR-4, Paragraph 6, Why document and disclose of methodology limited to planned generation only? What about planned transmission and interchange? Is it because there is more uncertainty for speculative generation than transmission? What about differences in modeling details require for different type of analyses, such as thermal or voltage, regional or local? It is our experience that more detailed representation (lower voltage facilities) is required for voltage analysis than thermal analysis. Perhaps the standard should state that additional detail may need to be added to the model to adequately represent the system for specific studies.
- E. Page SAR-5, Paragraph 1: If generation is considered in lieu of transmission reinforcement, the system must be able to withstand the loss of that generation plus another single contingency. The reason for this is that generation can be on or off due to economic and other factors after its installation, while transmission is almost always “on”.
- F. Other example of areas that should be considered for clarification is :
 - The “projected level of transfers” defined in the Standard – what does this include? Should it include/consider all transmission reservations including roll-over-rights?
- G. SAR-5, Bullet #1: In addition to the definition of “cascading outages” , clarification is needed for identification of a cascading state. For example, we are not sure that assumption of some percent overload, say 125% of emergency rating, is a good proxy for cascading.
- H. Page SAR-5, Bullet# 3: the second statement states that “The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A. “ Does this mean that probability should be assigned to at least all of the contingencies included in Table I.A.?
- I. Page SAR-5, Bullet #3: We believe that defining acceptable levels of risk will be a major undertaking. Isn't the level of risk is dependent upon the entity and/or perception? Using a deterministic methodology in the planning horizon for single contingency provides a margin to handle many multiple unplanned facility outages or unforeseen system conditions in operating horizon.
- J. Page SAR-5, Bullet# 4: Planned outages for maintenance or construction are generally managed in the operating horizon, and are granted only during specific load levels (off-peak), generation patterns, and interchange patterns when the transmission system is not expected to be fully utilized. We agree that clarification should be provided on how this information should be used in an assessment. However, as the scope of planning assessments is for the planning horizon of one year or more (SAR-4, paragraph 2) and not the operating horizon, we do not believe that the requirement for planning for maintenance outages should be included in planning assessments.
- K. Page SAR-5, Bullet# 5: We agree that some of the contingency categories should be reviewed. See our response to Item 1 C.
- L. Page SAR-5, Bullet# 6: We assume that short circuit current refers to fault duty or interrupting current.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice: KCP&L supports the recommendation that the Standard should allow for the development and use of probabilistic planning methods in reliability assessment.

Comments: KCP&L does not support any reclassification of the existing Category’s. The probability of occurrence of some contingencies may, in actuality, be very low. However, this should not diminish the importance of their assessment in the Category that they are currently found.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

KCP&L supports a requirement for reporting the status of implementing the mitigation plans. On a regional basis, mitigation plans should be reported by the Transmission Planner, as a minimum, on an annual basis through the regional model building process and assessed through the regional assessment studies performed by the Regional Reliability Coordinator.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Any out-of-cycle changes to the mitigation plan should be reported to the Reliability Coordinator and re-evaluated on an as-needed basis. Coordinated planning between other regions and entities will be critical.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments:

Planned outages are typically short-term (less than 1 year) and should be considered in the operating horizon. A planned outage is typically allowed during system load conditions when they will have minimal impact on the system.

KCP&L would prefer to clarify the existing Category B contingency that states “Loss of an element without a fault” be listed as the B5 contingency on the Table. Then, in Category C under Contingency 3, the revised wording should read “3. Category B (B1, B2, B3, B4, or B5) contingency, manual system adjustments, followed by another Category B (B1, B2, B3, B4, or B5) contingency. This will allow for the first contingency to include a planned outage (B5 without a fault) as well as a contingency with one of the fault conditions described in B1, B2, B3, and B4.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

KCP&L is aware of neighboring regional council differences in classification of Category B and C contingencies between SPP and MAPP.

6. Do you have any other comments on the SAR?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

In regards to developing accurate regional models, all known firm transmission service including rollover provisions for all firm transmission service should be included in the base case models.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments: “Loss of single component without a fault” should become Category B5 and be included in the listing of items in category C3.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice: Once an analysis has been performed, a subsequent “assessment” can easily dismiss low consequence events. However, low probability with high consequence should not be granted an exception. The initial premise of the Planning Standards did not contemplate probabilistic or Monte Carlo analysis.

Comments: “Good Cause Exception” must be carefully defined before entities are allowed to shield high consequence events regardless of probability of occurrence.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments: Having a “plan” that is not implemented is of no value.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

In the annual process to update power flow models, there are necessarily changes to the load forecast, use of the interconnected network, and financial constraints which must be taken into account. Reporting to the Regional Reliability Organization should include a discussion of substantive changes and reasons behind them. There should not be a judgment made by the RRO that the explanation is “adequate” so long as the explanation is made. The changes are critical information that must be taken into account when evaluating transmission service requests. Reporting should not be more frequent than the model-building cycle.

Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: Categories A through C.

No

Comments: The notion of including maintenance outages is to ensure that system restorations correctly evaluate single elements that would be removed in groups under a breaker-to-breaker outage analysis. The intent should not be to have any single element out for maintenance AND withstand the next contingency and should be stated as such.

4. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments: Yes. MAPP categorizes some contingencies differently.

5. Do you have any other comments on the SAR?

Comments: How will this SAR integrate with the Version 0 Standards?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

- Entergy believes that Category C events are more likely to occur than Category D events and should require higher performance expectations.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

- Entergy agrees that low consequence Category C events should be considered compliant. However, as we interpret Table I, a Category C

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

event that results in low consequences (e.g. no cascading) is already considered compliant since entities can drop load or curtail firm transfers to return to applicable thermal or voltage ratings.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments:

- It is not necessary to include planned maintenance outages in addition to Category A (no contingencies) because Category A plus planned outages equals Category B (single contingency). Therefore inclusion of maintenance outages in Category A is superfluous. The current standards do not require planned outages with Category A for that very reason.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Maintenance outages should be considered for only Category B and C contingencies.

Category D recognizes that cascading will occur in conjunction with the contingencies, so adding on more planned outages seems unnecessary, especially since Category D outages are very low probability events.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

- Entergy agrees the standard should not address resource planning. However, the standard should include requirements for the LSEs to provide forecast resource data required to develop power flow models. Accordingly, this standard should also apply to LSEs.

- In addition, the standard should require the Transmission Planner to document and describe the methodology used to plan the transmission system around the generation dispatch assumptions used by the Transmission Planner to meet the LSE load when and if the LSE provided resources do not equal the LSE provided load.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- Yes (consider planned outages in all Categories A through D).
- Yes (consider planned outages in some Categories only).

Please specify which Categories:

- No
- Comments:

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

In Florida, with the state requirements for the siting of facilities, the planning horizon should be adjusted from 5 YRS to 8 YRS. The 5 YR horizon is too short for some major transmission line projects and/or studies of transmission interconnections/upgrades for base load central station generating facilities.

6. Do you have any other comments on the SAR?

Comments:

- SAR Paragraph 6: “... the Standard shall require that system models be developed, maintained ...”
it is recommended that these models be “region-wide” system models that are developed utilizing a documented, consistent, region-wide criteria
- SAR Paragraph 10: “... a representative sample covering critical operating conditions ...”
It is recommended that this standard include specific requirements; such as, at what load levels and how many different load levels is intended by this part of the SAR. A suggestion would be 100% and 80%, and perhaps the 60% load level.
- SAR Paragraph 11 Bullet 4: Many grid operations difficulties occur when a line is scheduled out for maintenance. If this SAR is going to address required N-2 planning assessments, then it must be clear and specific regarding the conditions when N-2 assessments are appropriate and the specific criteria for N-2 assessments.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Additional Comments:

- The SAR should define specific planning voltage criteria for consistency between transmission owners/providers. Voltage Criteria should be specifically defined for normal condition and N-1 conditions and can be specified differently for:
 - Bulk power - non-load serving buses
 - Meshed/Looped - load serving buses
 - Radial - load serving buses
- The SAR should require joint transmission planning - at a minimum, joint transmission planning should be required between transmission service providers and their network service customers.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 1 and May 31, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

General Comment: It is the New York State Reliability Council's (NYSRC) position that NERC should not weaken existing criteria, including the NERC Planning Standards listed in the SAR as the starting point to be used in drafting a new standard. Therefore, with the advent of the Version 0 standards, we believe that there is no longer a need for this SAR. The comments in the "Consideration of Industry Comments" paper indicate that comments received in 2002 on SAR Version 1 were in favor of a standard on transmission assessment and planning, which was the SAR DT's reason for preparing this SAR. However, the Version 0 standards development process will now provide a transmission planning standard, without requiring the preparation of this new SAR. The comments below support our position that the existing Planning Standards should not be weakened.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

NYSRC Comment: In accordance with the NERC process for developing reliability standards, an entity may include a Regional Difference as part of the NERC standard if there is such a condition. Therefore, there is no need for the standard to include "good cause exceptions".

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Please explain your choice:

NYSRC Comments: Any of the above three choices would weaken the present NERC standards. Therefore, as answered in (a) above, there should be no changes to Categories B, C, and D as they now exist in the present Planning Standards.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

NYSRC Response: Updated transmission plans should be reported along with compliance assessments as required.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

NYSRC Comment: Again, the existing standards should not be weakened.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

NYSRC Comments: It is the NYSRC’s position that (1) NERC specifies minimum standards, (2) a Region may establish more stringent standards for its members separate from the NERC standards, and (3) it is unnecessary to include these more stringent standards within the framework of the NERC standards.

6. Do you have any other comments on the SAR?

NYSRC Comments: As stated above, it is the NYSRC’s position that there is no need to develop this SAR. However, despite this position, if the DT has sufficient support to go forward with a new standard, we have the following additional comments:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

1. SAR-4: Third paragraph – insert “and plans” after “Assessments”. The last sentence is not needed. A Region or other entity may have more stringent requirements than NERC – therefore, such a statement is not needed.
2. Fifth paragraph – define “applicable portion”. List the specific standards and measurements that are intended to be used as the starting point.
3. Bottom of page - We agree that a transmission planning standard should not include Resource Planning requirements. However, the NYSRC strongly believes that NERC should develop a separate Resource Planning Standard.
4. SAR-5: first bullet – replace “provide” with “consider”.
5. Third bullet – Is the probabilistic method referred to here considered a replacement for the NERC Criteria or a supplement to NERC Criteria? NERC should not allow such a method as a substitute for NERC criteria. I am not aware that NERC has completed an analysis to evaluate and compare the level of reliability of probabilistic criteria with NERC criteria. Such an evaluation would be needed.
6. Fifth bullet – This should be removed. This would be a weakening of the criteria.
7. The relationship with the Version 0 standards should be recognized in the SAR, including the mechanism of how this “Version 1” standard would replace Version 0.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

General Comment: It is the opinion of the Northeast Power Coordinating Council’s CP9 working group participating members that the existing NERC criteria should not be weakened, including the NERC Planning Standards listed in the SAR as the starting point to be used in drafting a new standard. The comments below support our position that the existing Planning Standards should not be weakened.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

NPCC believes that the relationship between the concept of the Version 0 Standards and all the developing Version 1 Standards needs to be consistent. The reliability attributes of the Version 0 standards must be “carried through and into” the Version 1 Standards and there needs to be coordination to ensure this occurs.

NPCC suggests leaving the categories as listed. Choice of any of the above would result in a weakened standard. We suggest no changes be made to Categories B, C, and D as they presently exist in the Planning Standards

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

No

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

In the northeast, the NPCC Annual Transmission Reviews address this and in addition NPCC keeps a “Major Projects List” to “track” BPS additions and modifications and includes transmission, generation and other major equipment identified as a BPS element.

NPCC suggests that the resultant NERC standard not be overly prescriptive in requirements for reporting progress/status on the standard and flexibility be afforded to allow various documentation and processes already in place to achieve compliance, and also we suggest it be done annually.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: We reiterate that the existing standards should not be weakened and request that the SAR be clarified to remove ambiguity regarding what is meant by “considering” a planned outage. Planned outages at present are considered however this is deemed an Operational Planning issue and is conducted so as to set Operational Limits for those conditions on a pre-contingency basis to allow for N-1 conditions.

This particular SAR will ultimately result in a “planning” Reliability Standard. The wording, as it has been phrased, infers that the system must be planned, designed and built to N-2 standards (i.e. a line out for maintenance on top of a circuit element outage). Treatment of planned outages should be considered to some extent and NPCC suggests the drafting team receive direction from the SAC regarding planned outages. NPCC suggests that planned outages should be considered only in categories in A through C.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

NPCC also would like to submit its definition of Bulk Power System, as follows, and would like it to be considered as a “building block” for the NERC BES definition.

- **Bulk Power System-BPS-(or BES in NERC documents) — The interconnected electrical systems within northeastern North America comprising generation and transmission facilities on which faults or disturbances can have a significant adverse impact outside of the local area. In this context, local areas are determined by the Council members.**

- NPCC suggests that any discussion and resultant determination of a definition for Cascading Outage be fully coordinated with the STDs 200 and 600. NPCC had submitted a suggested definition for the last posting of STD 200;

Cascading Outage- “The uncontrolled successive loss of Bulk Electric System elements that propagate beyond a defined area (Balancing Area’s) boundaries.”

Also NPCC recognizes that Resource Planning is not covered in the proposed Standard because it is considered as being handled by market mechanisms that are/will be in place or perhaps addressed in a separate standard. Therefore, NPCC assumes that the generation and load information required to perform the planning studies are provided as described in section II.A of the existing Planning Standards. If not, sections II.B, II.E and III of the existing Planning Standards should also be used as the starting point in drafting of the reliability requirements.

- NPCC is not in favor of removing references to “Applicable Ratings” as is suggested on SAR-5 fifth bullet. Despite the fact that the performance requirement would be “No Cascading Outages are Allowed”, the “Applicable Ratings” should always be respected.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments: However, major facility additions, delayed additions, or deletions that effect the reliability of the system could be included as part of the regional form 715 base case yearly filings and listed as changes from last year's cases. This would allow older cases to easily be updated and used.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- Yes (consider planned outages in all Categories A through D).
 Yes (consider planned outages in some Categories only).

Please specify which Categories:

- No
 Comments: I would modify C-3 since it has the same effect as or similar to a C-3 event to include (line out followed by a category B event).

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

This approach allows documentation of an assessment of low consequence to substitute for the expenditure of an unwarranted solution, but maintains the integrity of the event probability assessment. Since others may have different ideas of what is low probability, this approach would be best with sufficient justification of low probability.

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

No

Comments:

This reporting would constitute a logistical burden counterproductive to the total planning effort.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: Everyone in the group agreed that planned outages should be considered, but the group didn't agree on which categories to apply. About half believed they should be applied to all categories while the other half believed only A and B categories should have planned outages studied for the one year and beyond horizon.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

ISO-NE believes that the relationship between the concept of the Version 0 Standards and all the developing Version 1 Standards needs to be consistent. The reliability attributes of the Version 0 Standards must be “carried through and into” the Version 1 Standards; there needs to be coordination to ensure this occurs.

ISO-NE suggests leaving the categories as listed. Choice of any of the above would result in a weakened standard. We suggest no changes be made to Categories B, C, and D as they presently exist in the Planning Standards.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

In the northeast, the NPCC Annual Transmission Reviews address this and, in addition, NPCC keeps a “Major Projects List” to “track” BPS additions and modifications and includes transmission, generation and other major equipment identified as a BPS element.

ISO-NE suggests that the resultant NERC Standard not be overly prescriptive in requirements for reporting progress/status on the standard and flexibility be afforded to allow various documentation and processes already in place to achieve compliance; we also suggest it be done annually.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: We reiterate that the existing Standards should not be weakened and request that the SAR be clarified to remove ambiguity regarding what is meant by “considering” a planned outage. Planned outages, at present, are considered, however this is deemed an Operational Planning issue and is conducted so as to set Operational Limits for those conditions on a pre-contingency basis to allow for N-1 conditions.

This particular SAR will ultimately result in a “planning” Reliability Standard. The wording, as it has been phrased, infers that the system must be planned, designed and built to N-2 standards (i.e. a line out for maintenance on top of a circuit element outage). Treatment of planned outages should be considered to some extent and NPCC suggests the drafting team receive direction from the SAC regarding planned outages. NPCC suggests that planned outages should be considered only in categories A through C.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

ISO-NE would like to submit the NPCC definition of Bulk Power System, as follows, and would like it to be considered as a “building block” for the NERC BES definition.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

- **Bulk Power System-BPS-(or BES in NERC documents) — The interconnected electrical systems within {northeastern} North America comprising generation and transmission facilities on which faults or disturbances can have a significant adverse impact outside of the local area. In this context, local areas are determined by the Council members.**
- ISO-NE strongly suggests that any discussion and resultant determination of a definition for Cascading Outage be fully coordinated with the STDs 200 and 600. ISO-NE and NPCC had submitted a suggested definition for the last posting of STD 200;
Cascading Outage - “The uncontrolled successive loss of Bulk Electric System elements that propagate beyond a defined area (Balancing Area’s) boundaries.”

Recognizing that Resource Planning is not covered in the proposed Standard because it is considered as being handled by market mechanisms that are/will be in place or perhaps addressed in a separate standard, may we assume that the generation and load information required to perform the planning studies are provided as described in Section II.A of the existing Planning Standards?. If not, Sections II.B, II.E and III of the existing Planning Standards should also be used as the starting point in drafting of the reliability requirements.

- ISO-NE does not support removing references to “Applicable Ratings” as is suggested on SAR-5 fifth bullet. Despite the fact that the performance requirement would be “No Cascading Outages are Allowed,” the “Applicable Ratings” should always be respected.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments: Any inclusion of above mentioned options [re: under item (c)] may result in deteriorated standard. Therefore, for purposes of continued goals of reliability, it is our suggestion that no changes should be made in categories B, C and D (as they presently exist in the Planning Standards).

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Comments: In the Northeast, the NPCC Annual Transmission Reviews address this and in addition NPCC keeps a “Major Projects List” to “track” BPS additions and modifications and includes transmission, generation and other major equipment identified as a BPS element.

We also suggest that the resultant NERC standard not be overly prescriptive in requirements for reporting progress/status on the standard and flexibility be afforded to allow various documentation and processes already in place to achieve compliance, and moreover, we suggest that this be done annually.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- Yes (consider planned outages in all Categories A through D).
 Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: We reiterate that the existing standards should not be weakened and request that the SAR be clarified to remove ambiguity regarding what is meant by “considering” a planned outage. Planned outages are considered however this is deemed an Operational Planning issue and is conducted so as to set Operational Limits for those conditions on a pre-contingency basis to allow for N-1 conditions.

This particular SAR will ultimately result in a planning standard. The wording, as it has been phrased, infers that the system must be planned, designed and built to N-2 standards (i.e. a line out for maintenance on top of a circuit element outage). Treatment of planned outages should be considered to some extent and NPCC suggests the drafting team receive direction from the SAC regarding planned outages. We also concur with the NPCC/CP9 suggestion that planned outages should be considered only in categories in A through C.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

**Comment Form for Version 2 of “Assess Transmission Future Needs and Develop
Transmission Plans” SAR (2nd Posting)**

6. Do you have any other comments on the SAR?

Comments:

(1) We also resubmit our earlier suggested definition as given in the comments for the last(3rd)
posted version of STD 200;

Cascading Outage- “The uncontrolled successive loss of Bulk Electric System elements that
propagate beyond a defined area (Balancing Area’s) boundaries”

(2) The IMO also supports the comments submitted by ISO/RTO Council- Standards Review
Committee as well as the CP-9/NPCC Group

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice: SPP would like to see a definition of "good cause exceptions" at a minimum.

Comments: SPP encourages the development of probabilistic techniques to assess reliability but caution needs to be exercised prior to implementation to ensure support from all stakeholders.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments: SPP supports this reporting requirement, but notes that this burden should not be imposed more frequently than annually.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan? Although SPP is implementing a 2 year planning cycle, project updates are collected on an annual basis. To ensure compliance with reliability criteria, mitigation reviews are also provided on an annual basis consistent with the annual model building process. Updates due to new “out of cycle” projects or significant scope/timing changes associated with major projects in the approved regional expansion plan and its assessments are evaluated on an as-needed basis. Coordinated planning and model building using consistent definitions with neighboring regions/entities will be critical. Efforts should be undertaken to put data collection, modeling building and transmission assessment processes for neighboring regions/entities on the same cycles.

4. Existing Planning Standard 1.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: C.3. needs to be modified to address N-1-1 concerns. Category B (B1, B2, B3 or B4, including loss of an element without a fault) or in the alternative create Category B5 to Loss of an element without a fault. The later is preferred.

No

Comments: Planned outages are typically not evaluated more than one year in advance and are not scheduled during peak load conditions. However, the existing Planning Standard 1.A is problematic in that it requires the system to be designed to accommodate planned outages during peak load conditions.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments: SPP is aware of differences between SPP and the neighboring regions of ERCOT, MAPP and WECC.

6. Do you have any other comments on the SAR?

Comments: Implementation of this SAR needs to be coordinated with the activities of the Version 0 Standards Drafting Team.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

The outage listed in the existing categories are reasonable but, because we don't know all the specific details about a certain part of the system, there should be some mechanism to consider exceptions.

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

While an entity should be implementing plans to maintain or improve the reliability required by the standards, having to report on the implementation could become quite complicated. Plans are often changing to meet changing system conditions, sometimes so much so that what seemed reasonable to do last year is replaced by entirely new plans.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: *Planning the system should consider the need for planned outages but should not require the capability to plan outages at peak system loads.*

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

P SAR-3, Market Interface principles, question 5 – Depending on the level of public exposure of the load flow and stability models, generation cost data and stability parameter data may be deemed by some entities as confidential market information.

P SAR-4, II.A System Data – Needs to consider the difficulties, particularly for stand-alone transmission companies, in obtaining resource information so models can balance load and resources.

P SAR-5, third bullet – This may also go back to question 1 in this document but the statement, “There should be NERC approval of acceptable levels of risk” needs to be better defined. For example does this mean that a utility can’t decide to increase the operating temperature of a line conductor without NERC approval?

The SAR drafting team seems to have its arms around the issues and seems ready to proceed to Standard development.

E-mail: bbojorquez@ercot.com

Key to Industry Segment #'s:

- 1 – Trans. Owners**
- 2 – RTO's, ISO's, RRC's**
- 3 – LSE's**
- 4 – TDU's**
- 5 - Generators**
- 6 - Brokers, Aggregators, and Marketers
- 7 - Large Electricity End Users**
- 8 - Small Electricity Users**
- 9 - Federal, State, and Provincial
Regulatory or other Govt. Entities

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

- (a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

- (b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

- (c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

We suggest no changes be made to Categories B, C, and D as they presently exist in the Planning Standards. Choice of any of the above would result in a weakened standard and degraded reliability throughout NERC member systems.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Yes

No

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Periodic Transmission Reviews to address changes in plans and tracking lists of BPS additions and modifications (that would include transmission, generation and other major equipment identified as a BPS element).

The resultant NERC standard should not be overly prescriptive in requirements for reporting progress/status on the standard. Flexibility should allow for the various documentation and processes already in place to achieve compliance.

4. Existing Planning Standard I.A requires: “The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: *The existing standards should not be weakened*

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

Determination of a definition for Cascading Outage should be coordinated with the STDs 200 and 600.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments: **Category C events are more likely to occur than Category D events and should require higher performance expectations.**

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A.?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments: **Since the events are currently categorized correctly, 1.b and 1.c are not applicable. Low consequence Category C events should be considered compliant. However, as we interpret Table I, a Category C event that results in low consequences (e.g. no cascading) is already considered compliant since entities can drop load or curtail firm transfers to return to applicable thermal or voltage ratings.**

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments: **Too burdensome for the perceived benefits.**

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: **Categories A and B only.**

No

Comments: **The requirement to consider planned outages in addition to each Category A and B contingency should remain part of this planning standard. We agree with the SAR drafting team that exhaustive testing for every contingency described and every load level in each category is not practical.**

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments: **Not aware of any at this time. However, Regional Differences could develop and each request for a Regional Difference should be considered individually.**

6. Do you have any other comments on the SAR?

Comments:

In general, the NERC Standards need to have a common definition across the board for any definition used in a Standard. For example, the definition for "Cascading Outages" needs to be coordinated with the Standards Drafting Team (SDT) for the "Determine Facility Ratings, Operating Limits, and Transfer Capability" standard.

Southern agrees that the Standard should provide a clearer definition of “cascading outages.” We suggest that the following be considered:

Cascading — the uncontrolled successive loss of system elements triggered by contingencies which results in widespread electric service interruption 1) that drops 1000 MW of load or more or 2) that crosses control area boundaries.

In addition Southern recommends that the Standard provide a clearer definition of what is meant by “system stable.” We suggest that the following be considered:

System stable — For Category A and B simulations, system stable means that no generating units pull out of synchronism. For Category C events, system stable means that if units pull out of synchronism, 1) the resulting impedance swings are not out into the transmission system and 2) the total amount of generation lost because of out-of-step tripping does not exceed the control area operating reserve level.

The standard should include requirements for LSEs to provide forecast resource data as required in the current II.D standards, to facilitate development of power flow models. Accordingly, this standard should also apply to LSEs.

On page 4 of the SAR, bottom half of the page; there is a paragraph that discusses how the Transmission Planner should document generation dispatch. Comment: In relation to the methodology being used for incorporating planned generation assets in the model and how generation is dispatched, the type of each generating unit, the primary fuel type for each generating unit, and a dispatch order of the generating units should be required. In addition, a general description of the dispatch methodology used for the system should also be required. However, no cost information should be required.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

The Categories should be based on the probability of occurrence of the initiating events. A review of Table I (Standard IA) shows that the contingencies in the same Categories seem to have very different probabilities of occurrence. As such, a new category should be defined between Category C and Category D. The more probable Category D events and the less probable Category C events should be placed in this new category and not be allowed to cascade.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

WECC supports moving C.2 and C.9 to a new Category between the current C and D Categories. WECC Planning Standards do not support reclassification of C.3.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

A no-cascading performance requirement is needed for this new category.

There are Category C events, which have a very low probability of occurrence. Such events, even if they occurred should not lead to cascading, even though local facility ratings or voltage limits may be exceeded. Very often, the solution for such low probability contingencies would be to install a relay system to interrupt load or generation. The probability of relay misoperation to prevent potential problems resulting from the contingency may be higher than the probability of the contingency itself. Thus the impact on the users of the grid may not be significantly reduced. Nevertheless, the system reliability would be better served if we can add a category for such low probability contingencies (which would not result in cascading), and the risk of which is acceptable.

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

Since many of the transmission plans are dependent upon factors such as, resource plans, local load projections, new technology, permitting, to name a few, it would not be meaningful to report on the status of implementation of a transmission plan. In any case, if a potential transmission problem is not solved, it will show up again in subsequent years, so there will be pressure to solve it. This continuous “certification” would ensure that any potential transmission problem, once identified, would not be left unsolved even without NERC requiring status reports on implementation.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: A, B, and C (except C-3)

No

Comments:

All contingencies where a single point of failure could cause facilities to be lost should be tested for compliance with the standards even under planned maintenance conditions. However, it should never be necessary to exhaustively test every possible combination of outages. Those contingencies that are clearly not critical outages should not have to be simulated.

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

The existing NERC Standard C-9 (and C-2 for bus sectionalizing breakers) as it applies to WECC should be modified so that thermal limit and voltage limit violations are allowed for bus sectionalizing breaker failures. This is because bus sectionalizing breaker failure is a relatively low probability event. Use of a bus sectionalizing breaker should be encouraged because it reduces the impact of a disturbance to a portion of the load only. Without the proposed modification there is no incentive to use the sectionalizing breaker. However, under no conditions should system instability or cascading outages be allowed for bus sectionalizing breaker failures.

6. Do you have any other comments on the SAR?

– Comments:

1. On Page SAR-5 of the draft SAR, the third bullet states: "The Standard should allow for the development and use of probabilistic planning methods. The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A. There should be NERC approval of acceptable levels of risk."

The Standard should also allow for the use of Probabilistic Criteria. In WECC, Probabilistic Planning refers to the application of fixed planning standards to a given problem to determine the probable or expected load not served. Probabilistic Criteria is used to refer to adjusting the performance category based on the probability of the event for a specific facility. The performance category can move up or down depending on actual or planned performance. Therefore, Table 1 would be the starting point for making probabilistic criteria adjustments. Probabilistic adjusted criteria would be the basis for Probabilistic Planning.

For example, the NERC Planning Standards should follow what WECC is doing with regard to listing disturbances as a guide, but say that other disturbances with the same probability should be included. List the probability ranges (outages per year), Category B: ≥ 0.33 , Category C: 0.33 to 0.033; Category D1 (no cascading): 0.033 to .0033, Category D2: $< .0033$.

The standard should allow for changes in the required performance for given disturbances if a probability in another range has been established for a given disturbance.

WECC recommends that the approval of acceptable levels of risk be at the regional level.

NERC should require that the regional councils specify voltage dip and minimum frequency standards. NERC should not set the standards.

2. Page SAR-4 states that the Standard would not include requirements for Resource Planning. In order to develop any meaningful standard the resource part of the power system should be addressed by including standards for the modeling of existing resources, planned retirement of resources, and planned resources in the next 5 to 10 years time frame. This information will be necessary in order to assess whether future system can or can not meet the reliability standards.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

X Yes

No

X Comments: **I believe that an in depth investigation of the probability of each possible contingency occurring be investigated by NERC to determine each contingency's relative probability and those results used to re-rank the contingency list, if necessary.**

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

X Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

This is the best choice of the ones mentioned here but see my answer to 1.(b) above for another approach. This approach allows for some levels of performance between C and D such as restricting the performance to "no cascading or system instability" for some C and maybe even D events.

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

X Yes

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

No

Comments: **It's one thing to develop plans and another to follow through on them. PJM can offer suggestions on how this tracking could be accomplished.**

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

A plan is a plan at that point in time. Plans change. Periodic checks of implementation of plans can uncover these plan changes that should be allowed.

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: **Contingencies don't only happen when all lines are in service. Outages should be modeled during all types of contingency evaluation. This may be a fairly daunting task but this evaluation will help the system operators be prepared for the reality of operating the system in a less than ideal state. Possible ways to select lines to outage may be to look at lines with high unscheduled outage rates, lines close to sources of contamination, lines through areas that have historically had vegetation contact problems, and especially lines that when outaged can cause operating problems.**

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

Outage categories C1, C2 and C9 do not appear to be classified correctly as verified by the attached outage probability data. There is consistency between the categories except that C1, C2 and C9 outages have a much lower probability of occurrence than the other Category C outages.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

The C2 (with respect to a bus section breaker failure) and the C9 outages should be in this new category. Although these outages have extremely low probability, they should not cause cascading. This is especially true of C2, which is a single contingency failure of a bus section breaker. Therefore we favor adding a new category between Level C and D (or moving these two outages to Level D) with performance requirements of no cascading and system stable but with no requirement to be within applicable ratings.

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

Although this is not our preferred choice, allowing the use of "good cause exceptions" (which

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

we assume is the same as probabilistic methods which could move contingencies to a lower performance level although this is inconsistent with other statements in the SAR) to verify exceptions to the present categories would also be acceptable. For the C2 example, showing that these events statistically occur every 1200-1300 years and would not cause cascading problems on the system should provide enough evidence that a lower performance level is appropriate.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

A plan without a requirement to update progress on implementing the plan has little value. This is essential for an effective standard. This should not be an extensive reporting procedure and could easily be met during the subsequent compliance report.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Once a transmission plan is identified in a compliance report, progress on that project should be reported in subsequent compliance reports. If system conditions change, this should be described along with the consequences to the proposed plans. If project need goes away, the project can be cancelled. However, if the project need still exists and the responsible entity has not implemented a plan to correct the deficiency, it should be listed as non-compliant. Legitimate problems with regulatory and siting issues should be acceptable reasons for project delay.

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

This requirement should be addressed in operational planning studies (less than one year). This standard is not appropriate for Transmission Planning studies except possibly as a tool to measure or compare the robustness or availability of transmission plans. This is not an item that should require any compliance action.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

x Comments:

Although WECC has several requirements in its standards that are more stringent than the existing NERC criteria, it also has two standards that are less stringent (C2 and C9). Depending on the resolution of question #1 above, C2 and C9 may be a regional difference.

WECC has a formal Probabilistic Planning process that allows adjustment of performance levels of contingencies in either direction. As this SAR states that the existing NERC Table I is the minimum criteria for probabilistic methods, this will be a regional difference for WECC. This is discussed more in Item #6 below.

6. Do you have any other comments on the SAR?

x Comments:

Probabilistic Planning Methods: The handling of probabilistic criteria in the SAR seems quite convoluted, i.e. it can only be used to increase performance levels AND has to be approved by NERC. This is not the way probabilistic planning should work.

WECC presently has a process (Seven Step Reliability Performance Evaluation) to allow changes in performance requirements (both up and down) for specific outages based on rigorous analysis and monitoring actual performance. It is mostly applicable to requirements beyond the NERC criteria (such as outages of adjacent circuits on separate towers). Use of these methods should be allowed with approval of affected regions. This process should allow for movement below Table 1, i.e. moving Category C outage to Category D. One way to resolve this would be to replace the word “minimum” in the SAR to “starting”.

Applicable Ratings: There is a need to tighten up the methodology for Applicable Ratings to ensure that compliance with this standard is measurable. We assume that this will take place in the Determine Facility Ratings Standard although we are concerned about how this is progressing.

Transition to Operating Standards: The Planning Standards include multi-layered requirements for different types of outages, i.e., Level B single contingencies, Level C and D multiple contingencies. Compliance with these requirements is to be defined and monitored via the new Reliability Standards. However, once the system moves into the Operational timeframe (one year or less), Policy 2 presently requires meeting N-1 contingencies only with no requirements for Levels C and D. The transition between planning and operations needs further exploration.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “**Assess Transmission Future Needs and Develop Transmission Plans**” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “**Assess Transmission Future Needs and Develop Transmission Plans**” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Regulatory or other Govt. Entities

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Generally the B and C events are classified correctly. However, there is a need to reconsider the grouping of the D events on some consistent basis (e.g. such as using outage frequency as a determinant). There should also be some means to include double-circuit lines and buses as B events if their probability of outage is comparable to that of other category B contingencies.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A.?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

There are D contingencies that are probable although rare (e.g. loss of multiple circuits on separate tower lines on a common right-of-way). These contingencies may result in loss of load or generation but should not allow cascading. Other D contingencies such as loss of all lines on a multi-line corridor or the loss of a complete station would be difficult to contain. These events should be treated differently than the former.

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

It is not clear to whom the reporting would go to and how it would be used. Normally, reporting would be required for the regulatory process in the affected jurisdiction. The scope of that reporting would not be limited to reliability only but also other aspects of the transmission plan (e.g. customer connections, efficiency improvements, etc).

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- Yes (consider planned outages in all Categories A through D).
 Yes (consider planned outages in some Categories only).

Please specify which Categories: A to C

- No
 Comments:

A need to clarify what constitutes the “normal” condition when a facility (transmission or generation) is on a long duration planned outage (is it a day, a week, etc). The A to C contingency categories can then be applied to the “normal” condition as defined. The testing requirement could perhaps be stated in a way that leaves it to the judgement of the planning authority as to the critical combinations of outages that need to be tested.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

The basis of probabilistic planning, in our view, is to make planning decisions based on the metrics, such frequency, duration and impact, derived from probabilistic assessments. This is usually difficult to do in planning the bulk portion of the transmission system, since outage events are rare but their impact is significant (like multiplying infinity and zero). The categorization of contingencies in Table 1 using outage frequency as a determinant is a step in applying probabilistic techniques in this Standard but it is not probabilistic planning in its true sense. The

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

SAR development team should clarify what it intends with regard to “the use of probabilistic planning methods”.

We believe that the assumptions made for the amount, type and location of future supply are important considerations in assessing the future needs of transmission systems. The SAR drafting team should consider this forecast requirement in developing this Standard. Similarly, there is difficulty in separating planning for reliability and planning for overall system efficiency and economy, and the Standard must be clear on this differentiation.

The SAR drafting team should clarify through rules, tests, definitions, etc. the portion of an entity’s transmission system that shall be planned under the full NERC Standard and what portion may be exempted.

There should be a clear distinction between the appropriate use and application of RAS (or SPS) and “safety nets”.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

- (a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

- (b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

- (c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments:

We suggest no changes be made to Categories B, C, and D as they presently exist in the Planning Standards. Choice of any of the above would result in a weakened and degraded reliability standard throughout NERC member systems.

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Periodic Transmission Reviews to address changes in plans and tracking lists of BPS additions and modifications (that would include transmission, generation and other major equipment identified as a BPS element).

The resultant NERC standard should not be overly prescriptive in requirements for reporting progress/status on the standard. Flexibility should allow for the various documentation and processes already in place to achieve compliance.

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: *The existing standards should not be weakened*

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments:

Determining a definition for Cascading Outage should be coordinated with the STDs 200 and 600.

This standard should make it abundantly clear that it applies to both internal and external systems, that is the system under study and adjacent systems, or the entire interconnection if appropriate.

Seasonal and weather related variability should be considered in studies.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

- (a). Do you believe that the events in Categories B, C & D are classified correctly?
- Yes
- No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments: Category C events are more likely to occur than Category D events and should require higher performance expectations.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A.?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comments: Since the events are currently categorized correctly, 1.b and 1.c are not applicable.

Low consequence Category C events should be considered compliant. However, as we interpret Table I, a Category C event that results in low consequences (e.g. no cascading) is already considered compliant since entities can drop load or curtail firm transfers to return to applicable thermal or voltage ratings.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments: Too burdensome for the perceived benefits.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

4. Existing Planning Standard I.A requires: *"The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed"*.

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- Yes (consider planned outages in all Categories A through D).
 Yes (consider planned outages in some Categories only).

Please specify which Categories: **Categories A and B only.**

- No
 Comments: The requirement to consider planned outages in addition to each Category A and B contingency should remain part of this planning standard. We agree with the SAR drafting team that exhaustive testing for every contingency described and every load level in each category is not practical.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments: Not aware of any at this time. However, Regional Differences could develop and each request for a Regional Difference should be considered individually.

6. Do you have any other comments on the SAR?

Comments:

Southern agrees that the Standard should provide a clearer definition of "cascading outages". We suggest that the following be considered: The uncontrolled successive loss of system elements triggered by contingencies which results in widespread electric service interruption 1) that drops 1000 mw of load or more or 2) that crosses control area boundaries.

In addition, Southern recommends that the Standard provide a clearer definition of what is meant by "system stable". We suggest that the following be considered: For category A and B simulations, system stable means that no generating units pull out of synchronism. For Category C events, system stable means that if units pull out of synchronism, 1) the resulting impedance swings are not out into the transmission system and 2) the total amount of generation lost because of out-of-step tripping does not exceed the control area operating reserve level.

In general, the NERC Standards need to have a common definition across the board for any definition used in a Standard. For example, the definition for "Cascading Outages" needs to be coordinated with the Standards Drafting Team (SDT) for the "Determine Facility Ratings, Operating Limits, and Transfer Capability" standard.

It would also be beneficial to the generation sector if the SDT for this new Planning Standard could summarize the differences between the existing Planning Standards I.A, I.B, I.D, II.A, and II.D and the new Planning Standard as it is being developed. This would gauge the potential impact to the plants. The main concerns have been 1) how to address regional differences (primarily related to

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Category C events), 2) how to differentiate Table I's application to the Planning world versus the Operations world, and 3) how to state the requirements more clearly.

The standard should include requirements for LSEs to provide forecast resource data required to develop power flow models as required in the current II.D standards. Accordingly, this standard should also apply to LSEs.

In relation to the methodology being used for incorporating planned generation assets in the model and how generation is dispatched, the type of each generating unit, the primary fuel type for each generating unit, and a dispatch order of the generating units should be required. In addition, a general description of the dispatch methodology used for the system should also be required. However, no cost information should be required.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

X Comments: Need to see outage probability data in order to answer definitively.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

Based on good data, the probabilities of exiting C and D events could be estimated. The events could then be grouped into higher probability events (Category C) and lower probability events (Category D). AEP would be able to provide some outage data to support this analysis. Contact Ali Al-Fayez, Manager – Transmission Asset Performance (614 552-1649)

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

X Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice: Four categories are sufficient and generally understood by the industry. Specific changes that are supported by outage probabilities can be made, as appropriate, by moving Category C tests to Category D.

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

X Comments: “Good cause exceptions” can always be considered, but this approach should not be institutionalized.

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Yes

No

X Comments: The reporting requirements should not be burdensome, but they are needed to ensure a minimum level of accountability.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

A simple narrative explanation should be provided that explains what factors have eliminated the need for the transmission modification/addition or changed its timing. In cases where a modified solution has been developed, the Transmission Planner should demonstrate the effectiveness of the modified approach and compare to the original approach.

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: B, C and D

No

X Comments: For Categories where planned maintenance is considered, it should only be necessary to test the most significant planned outages, not all possible planned outages.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

No

Comments:

6. Do you have any other comments on the SAR?

No

Comments:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comments:

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

Keep the same categories as now exist, but allow for "good cause exceptions" upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice: Allow the flexibility for reasonable exceptions to the general categories based on frequency of occurrence. This may mean the possibility of a particular contingency moving up or down in category. This allowance permits appropriate exercise of engineering judgment in the planning process.

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories:

No

Comments: The first priority should be to clarify the requirements of the I.A table. Utilities/ regions are interpreting the table differently. What was the original basis for the contingency categories and required response in the table? Clarify whether the original intent was to perform thermal, voltage and stability screens for all categories and the frequency at which the screenings were intended to be performed.

It is impractical to expect all screenings of all categories on a frequent basis. It may be appropriate to state that the table is for general guidance and that transmission owners may determine frequency at which studies should be performed based on load growth, system loading and significance of changes to the system.

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comments:

6. Do you have any other comments on the SAR?

Comments: Resource planning cannot be excluded from the standard. Guidance should be provided on incorporation of resource data from all LSE's and how resource deficiencies in outyear models should be handled (e.g. model fictitious generation with no reactive capability to ensure sufficient reactive resources are planned for if power is purchased from off system in the future). The increasingly frequent changes in resource designations are causing greater uncertainty in performance of planning for reliable system operation.

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Note – This form is to comment on **Version 2** of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR.

The latest version of this SAR (TRNS_NDS_&_PLNS_01_02) is posted on the Standards web site at: <http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

E-mail this form between May 5 and June 5, 2004 to: sarcomm@nerc.com with “Comments” in the subject line.

If you have any questions about this Standards Draft Comment Form, please contact the Director of Standards – Gerry Cauley at 609-452-8060.

17TempleE330Background:

Version 1 of the “Assess Transmission Future Needs and Develop Transmission Plans” SAR was posted for a 30-day public comment period between April 2 and May 3, 2002. This first version was an abbreviated SAR, which included an “Industry Need” statement and a brief description of the proposed standard, but did not include a detailed description. The purpose of this first posting was to collect feedback from the industry on the following questions:

- Is there a reliability-related need for an Organization Standard to be developed on this topic?

If there is such a need, how should the scope of the SAR be changed?

- The scope of the SAR is fine as is
- The scope of the SAR should be expanded to include.....
- The scope of the SAR should be reduced to eliminate.....

In January 2004, the Standards Authorization Committee (SAC) appointed a Drafting Team (DT) to address industry answers and comments to the questions posed. The DT was also charged with refining the SAR and drafting a detailed description of the proposed standard in preparation for the 2nd posting of the SAR.

Most of the industry respondents indicated that there is indeed a reliability-related need to develop a standard to address transmission assessment and planning issues. Comments were received from many different sources, including individuals, small and large utilities, groups of utilities, and Regional Councils. The SAR DT considered the comments submitted by each industry participant, and revised the SAR to conform to the changes that were technically sound and appeared to represent a consensus of participants.

The revised SAR (Version 2) is posted on the NERC web site given in the blue box at the top of this form. Also posted is a Consideration of Comments document, in which the DT has responded to the original industry comments from 2002. You can find Version 1 of the SAR and industry comments on this version at the same web location.

Please review Version 2 of the SAR and complete this Comment Form to let the SAR DT know if you agree or disagree with the SAR DT’s assessment that this SAR is ready to be developed into a Standard.

Please Review Version 2 of the SAR and Answer the Following Questions

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

- Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.
 - Do you believe that the events in Categories B, C & D are classified correctly?

Yes

No

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

The Categories should be based on probability of occurrence of the initiating events. A review of Table I (Standard IA) show that the contingencies in the same Categories seem to have very different probabilities of occurrence.

Category D needs to be split into two categories, the more probable Category D events should not be allowed to cascade. For example, the new no cascading category should include:

loss of 2 units at a plant

loss of adjacent lines in a right of way

loss of multiple bus sections as a result of failure or delayed clearing of a bus tie or bus sectionalizing breaker

There is no defined performance level for 3 phase fault, stuck breaker, and loss of one line.

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

See A. For support, see the NERC/WECC Planning Standards

(c) Which of the following approaches do you favor regarding Table 1 of existing Planning Standard I.A?:

Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events.

Please explain your choice:

Create a new category between C and D with performance characteristics between that of the present Categories C and D.

Please explain your choice

A no-cascading performance requirement is needed.

There are Category C events, which have a very low probability of occurrence. Such events, even if occurred should not lead to cascading, even though local facility ratings or voltage limits may be exceeded. Very often, the solution for such low probability contingencies would be to install relay system to interrupt load or generation. The probability of relay misoperation to prevent potential problems resulting from the contingency may be higher than the probability of the contingency itself. In this case, the system reliability would be better serve if we can add a category for such low probability contingencies (which would not result in cascading), and the risk of which is acceptable.

Keep the same categories as now exist, but allow for “good cause exceptions” upon a showing of low probability of occurrence (and low consequence) of specific Category C events.

Please explain your choice:

Comment Form for Version 2 of “Assess Transmission Future Needs and Develop Transmission Plans” SAR (2nd Posting)

Comments:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

Yes

No

Comments:

Since many of the transmission plans are dependent upon factors such as, resource plans, local load projections, new technology, permitting, to name a few, it would not be meaningful to report on the status of implementation of a transmission plan. In any case, if a potential transmission problem is not solved, it will show up again in subsequent years, so there will be pressure to solve it. This continuous “certification” would ensure that any potential transmission problem, once identified, would not be left unsolved even without NERC requiring status reports on implementation.

3. If your answer to question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

4. Existing Planning Standard I.A requires: *“The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed”.*

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

Yes (consider planned outages in all Categories A through D).

Yes (consider planned outages in some Categories only).

Please specify which Categories: **A, B, and C (except C-3)**

No

Comments: **All contingencies where a single point of failure could cause facilities to be lost should be tested for compliance with the standards even under planned maintenance conditions. However, it should never be necessary to exhaustively test every possible combination of outages. Those contingencies that are clearly not critical outages should not have to be simulated.**

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

Comment Form for Version 2 of "Assess Transmission Future Needs and Develop Transmission Plans" SAR (2nd Posting)

Comments: The existing NERC Standard C-9 (and C-2 for bus sectionalizing breakers) as it applies to WECC should be modified so that thermal limit and voltage limit violations are allowed for bus sectionalizing breaker failures. However, under no conditions should system instability or cascading outages be allowed for bus sectionalizing breaker failures.

6. Do you have any other comments on the SAR?

– Comments: On Page SAR-5 of the draft SAR, the third bullet states: "The Standard should allow for the development and use of probabilistic planning methods. The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A. There should be NERC approval of acceptable levels of risk."

–

It appears to us that as written, the standard that flows from this SAR can only allow the probabilistic planning methods to make the standard more, not less, stringent than the existing Standard IA. This is not the way probabilistic planning methods should work. This statement also does not make sense when you read the next sentence, "There should be NERC approval of acceptable levels of risk." If the standard can only be more stringent, then there is no need for NERC to approve the level of risk, or even the probability of occurrence of the contingency. One way to resolve this issue would be to change the word "minimum" to "starting".

The NERC Planning Standards should follow what WECC is doing with regard to listing disturbances as a guide, but say that other disturbances with the same probability should be included. List the probability ranges (outages per year), Category B: ≥ 0.33 , Category C: 0.33 to 0.033; Category D1 (no cascading): 0.033 to .0033, Category D2: $< .0033$.

The standard should allow for changes in the required performance for given disturbances if a probability in another range has been established for a given disturbance.

NERC should specify voltage dip and minimum frequency standards similar to WECC (i.e., the voltage dip and minimum frequency should be within Applicable Ratings). We are not proposing that NERC set fixed values for these standards that would be the same throughout the ten NERC Regions.

Note: Questions refer to the 6 questions posed to industry on the SAR Comment Form, posted with SAR Version 2. Some of the question statements listed in this Table of Contents have been abbreviated or paraphrased from their original form. Question statements are shown in their entirety in the body of this document.

BACKGROUND

The Standard 500 **Standard Authorization Request (SAR)**, "Assess Transmission Future Needs and Develop Transmission Plans", was posted for a second public comment period from May 5 through June 5, 2004. The SAR Drafting Team (DT) asked industry participants to provide feedback on the revisions made to the SAR through a special Comment Form posted with the SAR (Version 2).

The SAR (Version 2) Comment Form posed 6 questions, some of which were multi-part. There was a total of 28 sets of comments returned, with 121 individuals responding. The industry comments can be viewed in their original format at:

ftp://www.nerc.com/pub/sys/all_updl/standards/sar/TRNS_NDS_&_PLNS_DT_01_02_Comments.pdf

The Standard 500: "Assess Transmission Future Needs and Develop Transmission Plans" SAR Drafting Team met and considered each of the sets of responses to the questions posed with the SAR (Version 2) Comment Form. The questions were aimed at gathering feedback on the changes made (or proposed to be made) to the SAR.

In consideration of these industry comments, the SAR DT drafted a third version of the SAR for consideration by the Standards Authorization Committee (SAC). The SAR (Version 3), if accepted by the SAC, will serve as specifications for a Standards Drafting Team to draft the new Standard 500. The Standards Drafting Team will have access to all industry comments made on the SAR (Version 2), and well as the SAR DT's consideration of these comments.

FORMAT OF THIS DOCUMENT

In this document, comments from industry participants are shown under each question, along with the SAR Drafting Team's summary of results and consideration of the comments, provided in [blue text](#) immediately under each question.

In most cases, a single response has been provided to show how the comments were considered. In some cases, the SAR DT provided a short note to indicate how a unique comment was considered.

At the end of this document there is an Industry Commenter Key listing each entity, industry segment (e.g., Transmission Owner, Generator, ISO, etc.) and the individual names of those responding via the SAR Comment Form.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give EVERY comment serious consideration in this process! If you feel there has been an error or omission, you can contact John Twitchell in the NERC office. John can be reached at 609-452-8060 or at John.Twitchell@nerc.net. Or you can contact this SAR's DT's Facilitator, Margaret Stambach at 518-384-1062 or at mr.stambach@ieee.org.

QUESTION 1(A): DO YOU BELIEVE THAT THE EVENTS IN TABLE I OF EXISTING PLANNING STANDARD I.A ARE CLASSIFIED CORRECTLY?

Question in its entirety:

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly? Comments?

SUMMARY:

YES (entities)	21	NO (entities)	5
YES (individuals)	76	NO (individuals)	42
	NO definitive answer		1 (1 entity, 1 individual) - AEP

Consideration by the SAR DT:

The SAR DT is recommending a review of existing Table I, including the likelihood, duration and impact of events, as well as the definition of applicable ratings (A/R). This review may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.

Entities responding YES to Question 1(a) – the events in Table I are classified correctly:

AES, AESO, ALLEGHENY, ATC, CWLP, DUKE, ENTERGY, ERCOT, IMO, ISONE, ISO/RTO, KCPL, MAAC/Horakh, MAAC/Kuras, NPCC, NYSRC, R.Snow, SCGEM, SERC, SOUTHERNCO, SPP, TVA, WESTAR (21 entities, 76 individuals).

SOME ENTITIES RESPONDING YES TO QUESTION 1 (a) [THE EVENTS ARE CLASSIFIED CORRECTLY] HAD THE FOLLOWING ADDITIONAL COMMENTS:	
AESO:	Generally the B and C events are classified correctly. However, there is a need to reconsider the grouping of the D events on some consistent basis (e.g. such as using outage frequency as a determinant). There should also be some means to include double-circuit lines and buses as B events if their probability of outage is comparable to that of other category B contingencies.
ENTERGY, SERC, SOUTHERNCO, SCGEM:	Entities listed believe that Category C events are more likely to occur than Category D events and should require higher performance expectations.
MAAC/Horakh	Categories B, C and D should be renamed as follows – Category B – High Probability Contingency Event

	<p>Category C – Medium Probability Contingency Event</p> <p>Category D – Low Probability Contingency Event</p> <p>The difference in the categories should NOT be stated in terms of how many elements are out of service, but rather should be stated in terms of the PROBABILITY of the initiating event that occurs. The difference in the categories is in the "stress" the system is allowed to experience and in the "fix" required. For B, a high probability event, stress should be low and the only fix allowed is system reinforcement. For D, a low probability event, severe system stress is allowed, and system reinforcement is not mandated. C is somewhere in between, a medium probability, with medium system stress permitted, and some loss of load and/or curtailment of transfers allowed in lieu of system reinforcement. Table I can then be simplified by removing the column labeled "Elements Out of Service", because it is unnecessary and not relative. Actually, the columns labeled "Thermal Limits", "Voltage Limits", "System Stable" and "Cascading Outages" can be eliminated too, because they are the same for each Category A, B and C (but notes for each column should be retained).</p>
<p>MAAC/Kuras:</p>	<p>I believe that an in depth investigation of the probability of each possible contingency occurring be investigated by NERC to determine each contingency's relative probability and those results used to re-rank the contingency list, if necessary.</p>
<p>R.Snow:</p>	<p>Without a rigorous Probabilistic Risk Analysis, moving any of these events to a category D event is bad practice. All of the events have occurred at one time or another, especially circuit breaker and bus faults. Moving them to a category D essentially removes them from requiring action to mitigate/solve the impact on reliability.</p>
<p>WESTAR:</p>	<p>"Loss of single component without a fault" should become Category B5 and be included in the listing of items in category C3</p> <p><i>{See similar comments: SPP comment under Question 4, Choice (2) and KCPL comment under Question 4, Choice (3)}.</i></p>

QUESTION 1(B): IF YOUR ANSWER TO THE ABOVE QUESTION IS NO, HOW WOULD YOU RE-CLASSIFY THE EVENTS?

Question in its entirety:

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(a). Do you believe that the events in Categories B, C & D are classified correctly?

(b). If your answer to (a) is No, how would you re-classify the events? If you have data to support your answer, please provide contact information for the individual responsible for the data.

SUMMARY: 5 entities (42 individuals) answered NO to Question 1(a) and therefore responded to Question 1(b).

Also included in this section are two miscellaneous comments on whether events are classified correctly: one comment from AEP, who had no definitive answer to Question 1(a), and one comment from MAPP, who answered NO to Question 1(a).

Consideration by the SAR DT:

The SAR DT is recommending a review of existing Table I, including the likelihood, duration and impact of events, as well as the definition of applicable ratings (A/R). This review may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.

Entities responding NO to Question 1(a) – the events in Table I are NOT classified correctly:

AMEREN, BPA, MAPP, MEC and WECC (WECC-1 plus WECC-2). (5 entities, 42 individuals)

ENTITIES RESPONDING TO QUESTION 1(b) [i.e., ENTITIES RESPONDING NO TO QUESTION 1(a) - THE EVENTS ARE NOT CLASSIFIED CORRECTLY]	
Ameren	All category C outages that have a direct impact on serving load because of the system configuration (straight bus or tapped load) should be reclassified, including C-1, C-2, C-5, and C-9 to provide more latitude. For category C events, we should be more concerned that the system holds together and not that the local load may be at risk for these multiple contingency events.
BPA	Outage categories C1, C2 and C9 do not appear to be classified correctly as verified by the attached <i>outage probability data</i> . There is consistency between the categories except that C1, C2 and C9 outages have a much lower probability of occurrence than the other Category C outages. {See Attached Companion Document: Excel File – “BPAdat”. Or contact: Marv Landauer, (503) 230-4105, mjlandauer@bpa.gov}
MAPP & MEC	MAPP and MEC would reclassify certain low probability events such as Category C1 events, C2 events, certain Category C3 events (two transformers, transmission circuit plus a transformer, two transmission circuits, DC line plus a transformer, DC line plus a transmission circuit, and two DC lines), C6 events, C7 events, C8 events, and C9 events to either a new

	<p>category between C and D with performance characteristics between that of the present Categories C and D or to Category D. [MEC supports creating a new category between C & D].</p> <p>MAPP and MEC would require that the interconnected transmission system be planned, designed, and constructed to protect for instability, cascading, and uncontrolled separation for the low probability events in the new sub-category. Regions should develop procedures for determining that systems are properly protected for instability, cascading and uncontrolled separation.</p> <p>MAPP & MEC believe the attached <i>outage probability data</i> supports this new reclassification by demonstrating that the events that MAPP & MEC recommend for reclassification are the low probability Category C events.</p> <p>{See Attached Companion Document: Word File – "MAPP-MECdata". Or contact: Tom Mielnik, (563) 333-8129, tcmielnik@midamerican.com}</p>
MEC	<p>MidAmerican Energy believes the interconnected transmission system should be planned, designed, and constructed to withstand high probability events and to withstand low probability events with significant negative consequences.</p> <p>MidAmerican believes it is a waste of the ratepayers' money to plan, design, and construct the interconnected transmission system for low probability events without significant negative consequences.</p>
WECC-1 & WECC-2	<p>The Categories should be based on the probability of occurrence of the initiating events. A review of Table I (Standard I.A) shows that the contingencies in the same Categories seem to have very different probabilities of occurrence.</p>
WECC-1	<p>Category D needs to be split into two categories, the more probable Category D events should not be allowed to cascade. For example, the new "No Cascading" category should include:</p> <p>Loss of 2 units at a plant</p> <p>Loss of adjacent lines in a right of way</p> <p>Loss of multiple bus sections as a result of failure or delayed clearing of a bus tie or bus sectionalizing breaker.</p> <p>There is no defined performance level for 3 phase fault, stuck breaker, and loss of one line.</p> <p>For support of this position, see the NERC/WECC Planning Standards</p>
WECC-2	<p>A new category should be defined between Category C and Category D. The more probable Category D events and the less probable Category C events should be placed in this new category and not be allowed to cascade. This WECC group supports moving C.2 and C.9 to a new Category between the current C and D Categories. WECC Planning Standards do not support reclassification of C.3.</p>

MISCELLANEOUS COMMENTS ON WHETHER EVENTS ARE CLASSIFIED CORRECTLY	
AEP	<p>Need to see outage probability data in order to answer definitively.</p> <p>Based on good data, the probabilities of existing C and D events could be estimated. The events could then be grouped into higher probability events</p>

	<p>(Category C) and lower probability events (Category D). AEP would be able to provide some outage data to support this analysis.</p> <p>{Contact Ali Al-Fayez, Manager – Transmission Asset Performance (614 552-1649)}</p>
<p>MAPP:</p>	<p>The definition of applicable ratings needs to be clarified. The SAR DT should also indicate if it is feasible to have different applicable ratings for different categories of events.</p> <p>The SAR DT should review the history of the original classification. This review should include all classes. If outage statistics are used to classify events, how many years of data are appropriate? If the data window is too small, the results will be skewed. Moreover, is it appropriate to use outage data for all these categories of events? Outage data over a long period of time may provide insight into equipment performance, but is it appropriate to reflect weather related contingency events – the data may not reflect the effect of a once in a 100 year storm?</p> <p>Consideration by the SAR DT: <i>The SAR DT is recommending that the new Standard clarify ambiguities in performance requirements, specifically cascading outages and A/R. We are also recommending the new Standard clarify that different ratings may be applicable to different categories of events, and perhaps to different types of events within a category (specified by entities in accordance with STD 600).</i></p>

QUESTION 1(C): WHICH APPROACH DO YOU FAVOR?: (1) KEEP THE SAME CATEGORIES AND RE-CLASSIFY CERTAIN EVENTS AS CATEGORY D, (2) CREATE A NEW CATEGORY BETWEEN C & D, (3) KEEP THE SAME CATEGORIES AND ALLOW FOR GOOD CAUSE EXCEPTIONS.

Question in its entirety:

1. Some members of the SAR drafting team believe that certain Category C events, as defined in Table 1 of existing Planning Standard I.A, are much less likely to occur than other events in Category C. It is felt that certain specific Cat. C events could be re-classified as Cat. D upon showing a low probability of occurrence (and low consequence) of these events.

(c). Which of the following approaches do you favor regarding Table 1 of existing Planning standard I.A?

(1) Keep the same categories as now exist and re-classify the low probability (and low consequence) events as Category D events. Please explain your choice.

(2) Create a new category between C and D with performance characteristics between that of the present categories C and D. Please explain your choice.

(3) Keep the same categories as now exist, but allow for "good cause exceptions" upon showing a low probability of occurrence (and low consequence) of specific Category C events. Please explain your choice.

SUMMARY:

Entities supporting Choice (1)	4 (9 individuals)
Entities supporting Choice (2)	7 (46 individuals)
Entities supporting Choice (3)	6 (24 individuals)
Entities supporting NONE of the choices	11 (44 individuals)

Consideration by the SAR DT:

The SAR DT is recommending a review of existing Table I, including the likelihood, duration and impact of events, as well as the definition of applicable ratings (A/R). This review may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.

Since there was no clear consensus on how to address re-classification of events, the SAR DT feels that a thorough review of existing Table I will assure that events are properly classified for the new Standard.

Entities supporting Choice (1) – keep same categories and re-classify certain events as Cat. D

AEP, AMEREN, CWLP, MAPP (4 entities, 9 individuals)

ENTITIES SUPPORTING CHOICE (1) – KEEP SAME CATEGORIES AND RE-CLASSIFY CERTAIN EVENTS AS CATEGORY D	
AEP	Four categories are sufficient and generally understood by the industry. Specific changes that are supported by outage probabilities can be made, as appropriate, by moving Category C tests to Category D.
AMEREN	Reclassify C-1,C-2, and C-9 to category D (less probable events). C-3 (line and a generator combination) should be reclassified as category B event (more probable than other C-3 events. Also, why is a loss of a tower line with two circuits category C (C-5) while loss of a tower line with 3 circuits is category D (D-6), though a probability of loss of a tower line may be the same ? We may want to be consistent in categorizing the event – loss of a multi-circuit tower line.
CWLP	(No explanation given.)
MAPP	If the events are low probability, then some should be considered for moving to C or D.
MISCELLANEOUS COMMENT ON CHOICE (1) – KEEP SAME CATEGORIES & RE-CLASSIFY CERTAIN EVENTS AS CATEGORY D	
MEC	MidAmerican does NOT support this choice, since MEC believes that reclassifying less likely Category C events as Category D events will result in planners ignoring low-probability contingencies that result in significant consequences: cascading, uncontrolled separation, and instability.

Entities supporting Choice (2) – create new category between C & D.

AESO, BPA, CWLP, MAAC/Kuras, MAPP, MEC, WECC (WECC-1 plus WECC-2). (7 entities, 46 individuals)

ENTITIES SUPPORTING CHOICE (2) – CREATE A NEW CATEGORY BETWEEN C & D	
AESO	There are D contingencies that are probable although rare (e.g. loss of multiple circuits on separate tower lines on a common right-of-way). These contingencies may result in loss of load or generation but should not allow cascading. Other D contingencies such as loss of all lines on a multi-line corridor or the loss of a complete station would be difficult to contain. These events should be treated differently than the former.
BPA	The C2 (with respect to a bus section breaker failure) and the C9 outages should be in this new category. Although these outages have extremely low probability, they should not cause cascading. This is especially true of C2, which is a single contingency failure of a bus section breaker. Therefore we favor adding a new category between Level C and D (or moving these two outages to Level D) with performance requirements of no cascading and system stable but with no requirement to be within applicable ratings. <i>[See similar comment from WECC-2 under Question 5, Regional Differences]</i>

CWLP	Multiple contingencies have lower and varying probabilities of occurrence.
MAAC/Kuras	This is the best choice of the ones mentioned here but see my comment in 1.(a) above for another approach. This approach allows for some levels of performance between C and D such as restricting the performance to "no cascading or system instability" for some C and maybe even D events.
MAPP & MEC	Improvements should be planned for those Category C events that are high probability events regardless of the consequences. Planners should also review all Category C events for instability, cascading, and uncontrolled separation. Improvements should be planned for those Category C events (both high probability and low probability events) which have significant consequences, that is, that result in instability, cascading, and uncontrolled separation.
MEC	The approach that results in the most appropriate transmission system design is the one recommended by MEC. It is MEC's belief that the intent of the drafting team that originally developed the existing NERC Planning Standards was to require the NERC member to plan to protect for instability, cascading, and uncontrolled separation for Category C events.
WECC-1 & WECC-2	<p>A "No Cascading" performance requirement is needed for this new category.</p> <p>There are Category C events, which have a very low probability of occurrence. Such events, even if they occurred, should not lead to cascading, even though local facility ratings or voltage limits may be exceeded. Very often, the solution for such low probability contingencies would be to install a relay system to interrupt load or generation.</p> <p>The probability of relay misoperation to prevent potential problems resulting from the contingency may be higher than the probability of the contingency itself. Thus the impact on the users of the grid may not be significantly reduced. Nevertheless, the system reliability would be better served if we can add a category for such low probability contingencies (which would not result in cascading), and the risk of which is acceptable.</p>

Entities supporting Choice (3) – keep same categories and allow for good cause exceptions.

ATC, BPA, DUKE, KCPL, SPP, TVA, WESTAR. (6 entities, 24 individuals).

{Note: BPA not counted in this choice. BPA counted in Choice (2) "New Category", since that is their preferred choice}

ENTITIES SUPPORTING CHOICE (3) – KEEP SAME CATEGORIES AND ALLOW FOR GOOD CAUSE EXCEPTIONS	
ATC	The outages listed in the existing categories are reasonable but, because we don't know all the specific details about a certain part of the system, there should be some mechanism to consider exceptions.
BPA	Although this is not our preferred choice, allowing the use of "good cause exceptions" (which we assume is the same as probabilistic methods which could move contingencies to a lower performance level although this is inconsistent with other statements in the SAR) to verify exceptions to the present categories would also be acceptable. For the C2 example, showing that these events statistically occur every 1200-1300 years and would not cause cascading problems on the system should provide enough evidence that a lower performance level is appropriate.

DUKE	Allow the flexibility for reasonable exceptions to the general categories based on frequency of occurrence. This may mean the possibility of a particular contingency moving up or down in category. This allowance permits appropriate exercise of engineering judgment in the planning process.
KCPL	KCPL supports the recommendation that the Standard should allow for the development and use of probabilistic planning methods in reliability assessment. However, KCP&L does not support any reclassification of the existing Categories. The probability of occurrence of some contingencies may, in actuality, be very low. However, this should not diminish the importance of their assessment in the Category that they are currently found.
SPP	SPP would like to see a definition of "good cause exceptions" at a minimum. SPP encourages the development of probabilistic techniques to assess reliability but caution needs to be exercised prior to implementation to ensure support from all stakeholders.
TVA	This "good cause exception" approach allows documentation of an assessment of low consequence to substitute for the expenditure of an unwarranted solution, but maintains the integrity of the event probability assessment. Since others may have different ideas of what is low probability, this approach would be best with sufficient justification of low probability.
WESTAR	Once an analysis has been performed, a subsequent "assessment" can easily dismiss low consequence events. However, low probability with high consequence should not be granted an exception. The initial premise of the Planning Standards did not contemplate probabilistic or Monte Carlo analysis. "Good Cause Exception" must be carefully defined before entities are allowed to shield high consequence events regardless of probability of occurrence.
MISCELLANEOUS COMMENTS ON CHOICE (3) - KEEP SAME CATEGORIES & ALLOW FOR GOOD CAUSE EXCEPTIONS	
AEP	"Good cause exceptions" can always be considered, but this approach should not be institutionalized.
MAPP & MEC	MAPP & MEC believe that allowing for "good cause exceptions" is not the preferable approach. We believe that the events listed by MAPP & MEC for reclassification are much less likely than the other Category C events generally throughout NERC. This means that these events should be reclassified in general throughout NERC and not just in certain "good cause exceptions". (Although, it should be noted that MAPP & MEC do support Regional Differences where appropriate.) Besides, there are issues associated with the development and utilization of a process for approving "good cause exceptions".
NYSRC	In accordance with the NERC process for developing reliability standards, an entity may include a Regional Difference as part of the NERC standard if there is such a condition. <u>Therefore, there is no need for the standard to include "good cause exceptions".</u>

Entities supporting NONE of the 3 choices:

ENTERGY, ERCOT, IMO, ISONE, ISO/RTO, MAAC/Horakh, NPCC, NYSRC, SCGEM, SERC, SOUTHERNCO, (11 entities, 44 individuals).

ENTITIES SUPPORTING NONE OF THE CHOICES - NO CHANGES TO CATEGORIES/EVENTS	
ENTERGY, SCGEM, SERC, SOUTHERNCO	Since the events are currently categorized correctly, above Questions 1 (b) and 1 (c) are not applicable. Entities listed agree that low consequence Category C events should be considered compliant. However, as we interpret Table I, a Category C event that results in low consequences (e.g. no cascading) is already considered compliant since entities can drop load or curtail firm transfers to return to applicable thermal or voltage ratings.
ERCOT, IMO, ISONE, ISO/RTO, NPCC, NYSRC	Any of the above three choices would weaken the present NERC standards. All entities listed take the position that there should be No Changes to Categories B, C, and D as they now exist in the present Planning Standards.
MAAC/Horakh	NONE OF THE ABOVE. Keep the three categories, but rename them as in 1.a. above. Adding an additional category would introduce too much confusion in planning the system. Assuming that the contingencies in B, C and D are already in their correct probability categories, no changes need to be made. If someone could prove that a contingency in B is Low Probability the same as the contingencies in D, that contingency could be moved.

QUESTION 2: DO YOU BELIEVE THE STANDARD SHOULD REQUIRE REPORTING ON IMPLEMENTING THE TRANSMISSION PLANS?

Question in its entirety:

2. Do you believe the standard should include requirements for reporting on the progress or status of *implementing* the plans developed in accordance with this standard?

SUMMARY:

YES (entities)	13	NO (entities)	13
YES (individuals)	60	NO (individuals)	53
	NO definitive answer	1 (1 entity, 7 individuals) - MAPP	

Consideration by the SAR DT:

There was no clear consensus on whether reporting on the progress or status of implementing the plans should be included in the Standard. This SAR Drafting Team is recommending that the new Standard address requirements for reporting (perhaps to the Regions) on the progress or status of implementing the plans, but such requirements should not impose undue burdens upon transmission entities.

Any such reporting requirements shall be consistent with the Resource & Transmission Adequacy's RTATF Recommendation #2: "Among other items, the new Reliability Standards should clearly define the key elements of an acceptable mitigation plan to achieve compliance with the standard(s) and a general process to ensure implementation of the mitigation plan".

Entities responding YES to Question 2 – the standard SHOULD require implementation reporting.

AEP, AMEREN, BPA, IMO, ISONE, ISO/RTO, ERCOT, KCPL, MAAC/Horakh, MAAC/Kuras, NPCC, NYSRC, R.Snow, SPP, WESTAR (13 entities, 60 individuals)

SOME ENTITIES RESPONDING YES TO QUESTION 2 [THE STANDARD <u>SHOULD</u> REQUIRE IMPLEMENTATION REPORTING] HAD THE FOLLOWING ADDITIONAL COMMENTS:	
AEP	The reporting requirements should not be burdensome, but they are needed to ensure a minimum level of accountability.
AMEREN	The reporting requirement should not be onerous.
BPA	A plan without a requirement to update progress on implementing the plan has little value. This is essential for an effective standard. This should not be an extensive reporting procedure and could easily be met during the subsequent compliance report.
KCPL	KCP&L supports a requirement for reporting the status of implementing the mitigation plans. On a regional basis, mitigation plans should be reported by the Transmission Planner, as a minimum, on an annual basis through the regional model building process and assessed through the regional

Consideration of Comments on SAR Version 2 of Standard 500: "Assess Transmission Future Needs and Develop Transmission Plans", posted for public comment May 5 – June 5, 2004.

	assessment studies performed by the Regional Reliability Coordinator.
MAAC/Kuras	It's one thing to develop plans and another to follow through on them. PJM can offer suggestions on how this tracking could be accomplished.
R.Snow	Developing plans without a follow up program is a waste of time and money. One of the most telling comments from the August Blackout report was that a number of the items were the same as in other blackouts.
SPP	SPP supports this reporting requirement, but notes that this burden should not be imposed more frequently than annually.
WESTAR	Having a "plan" that is not implemented is of no value.

Entities responding NO to Question 2 – the standard SHOULD NOT require implementation reporting.

AES, AESO, ALLEGHENY, ATC, CWLP, DUKE, ENTERGY, MEC, SCGEM, SERC, SOUTHERNCO, TVA, WECC-1, WECC-2 (13 entities, 53 individuals)

SOME ENTITIES RESPONDING NO TO QUESTION 2 [THE STANDARD SHOULD NOT REQUIRE IMPLEMENTATION REPORTING] HAD THE FOLLOWING ADDITIONAL COMMENTS:	
AES	AES does not favor an implementation report. However, major facility additions, delayed additions, or deletions that effect the reliability of the system could be included as part of the regional form 715 base case yearly filings and listed as changes from last year's cases. This would allow older cases to easily be updated and used.
AESO	It is not clear to whom the reporting would go to and how it would be used. Normally, reporting would be required for the regulatory process in the affected jurisdiction. The scope of that reporting would not be limited to reliability only but also other aspects of the transmission plan (e.g. customer connections, efficiency improvements, etc).
ATC	While an entity should be implementing plans to maintain or improve the reliability required by the standards, having to report on the implementation could become quite complicated. Plans are often changing to meet changing system conditions, sometimes so much so that what seemed reasonable to do last year is replaced by entirely new plans.
MEC	MidAmerican Energy believes that this standard should not include requirements for reporting on the progress or status of implementing the plans developed in accordance with this standard. There are too many conditions beyond the control of the NERC member for this to be a part of a standard requiring compliance review. Complex environmental, regulatory, and political issues prevent many transmission facilities from being constructed or being constructed in a scheduled manner. The Not-In-My-Back-Yard philosophy has hit even the rural areas so that there is no part of the NERC area where a NERC member can confidently predict completion of transmission system improvements in plans. Further, conditions can change even during a year to such an extent that compliance review for implementation from one year to the next is problematic. Further, regulatory oversight provides for appropriate review of plan implementation anyway. MidAmerican urges that the SAR drafting team not pursue this well-meaning but problematic approach.

SCGEM, SOUTHERNCO	Too burdensome for the perceived benefits.
TVA	This reporting would constitute a logistical burden counterproductive to the total planning effort.
WECC-1 & WECC-2	Since many of the transmission plans are dependent upon factors such as, resource plans, local load projections, new technology, permitting, to name a few, it would not be meaningful to report on the status of implementation of a transmission plan. In any case, if a potential transmission problem is not solved, it will show up again in subsequent years, so there will be pressure to solve it. This continuous "certification" would ensure that any potential transmission problem, once identified, would not be left unsolved even without NERC requiring status reports on implementation.

MISCELLANEOUS COMMENT ON WHETHER THE STANDARD SHOULD REQUIRE IMPLEMENTATION REPORTING (Neither Yes/No Box Checked)	
MAPP	Requirements for reporting on the progress or status of implementing the plans should be left to the regions and appropriate regulatory bodies. The MAPP Regional Transmission Committee currently has a regional planning process for compliance for implementing transmission plans.

QUESTION 3: IF YOUR ANSWER TO QUESTION 2 IS YES, HOW WOULD YOU PROPOSE ACCOUNTING FOR CHANGES IN A TRANSMISSION PLAN?

Question in its entirety:

3. If your answer to Question 2 is Yes, given that transmission plans change over time as modeling assumptions, systems and plans change, how would you propose accounting for changes in a Transmission Plan?

SUMMARY: 13 entities (60 individuals) answered YES to Question 2 and therefore responded to Question 3.

Consideration by the SAR DT:

There was no clear consensus on whether reporting on the progress or status of implementing the plans should be included in the Standard. This SAR Drafting Team is recommending that the new Standard address requirements for reporting (perhaps to the Regions) on the progress or status of implementing the plans, but such requirements should not impose undue burdens upon transmission entities.

Any such reporting requirements shall be consistent with the Resource & Transmission Adequacy's RTATF Recommendation #2: "Among other items, the new Reliability Standards should clearly define the key elements of an acceptable mitigation plan to achieve compliance with the standard(s) and a general process to ensure implementation of the mitigation plan".

Entities responding YES to Question 2 (The standard SHOULD require implementation reporting) and therefore responding to Question 3 (How would you account for changes in a Transmission Plan?).

AEP, AMEREN, BPA, ERCOT, IMO, ISONE, ISO/RTO, KCPL, MAAC/Horakh, MAAC/Kuras, NPCC, NYSRC, R.Snow, SPP, WESTAR (13 entities, 60 individuals)

ENTITIES RESPONDING TO QUESTION 3 – HOW WOULD YOU PROPOSE ACCOUNTING FOR CHANGES IN A TRANSMISSION PLAN? [i.e., ENTITIES RESPONDING YES TO QUESTION 2 - THE STANDARD <u>SHOULD</u> REQUIRE IMPLEMENTATION REPORTING]:	
AEP	A simple narrative explanation should be provided that explains what factors have eliminated the need for the transmission modification/addition or changed its timing. In cases where a modified solution has been developed, the Transmission Planner should demonstrate the effectiveness of the modified approach and compare to the original approach.
AMEREN	Provide the following: (i) Annual update with a short note to document changes. (ii) Smaller projects (cap bank addition, change of terminal equipment like switches, wavetraps, or CT) may be combined as a group in such reporting to avoid providing a long list of updates.
BPA	Once a transmission plan is identified in a compliance report, progress on that project should be reported in subsequent compliance reports. If system conditions change, this should be described along with the consequences to the proposed plans. If project need goes away, the project can be canceled.

Consideration of Comments on SAR Version 2 of Standard 500: "Assess Transmission Future Needs and Develop Transmission Plans", posted for public comment May 5 – June 5, 2004.

	<p>However, if the project need still exists and the responsible entity has not implemented a plan to correct the deficiency, it should be listed as non-compliant. Legitimate problems with regulatory and siting issues should be acceptable reasons for project delay.</p>
<p>ERCOT, IMO, ISONE, ISO/RTO, NPCC</p>	<p>All entities listed favor periodic transmission reviews to address changes in plans. In the northeast, the NPCC Annual Transmission Reviews address this and in addition NPCC keeps a "Major Projects List" to "track" BPS additions and modifications and includes transmission, generation and other major equipment identified as a BPS element. The entities suggest that the resultant NERC standard not be overly prescriptive in requirements for reporting progress/status on the standard and flexibility be afforded to allow various documentation and processes already in place to achieve compliance. They suggest it be done annually.</p>
<p>KCPL</p>	<p>Any out-of-cycle changes to the mitigation plan should be reported to the Reliability Coordinator and re-evaluated on an as-needed basis. Coordinated planning between other regions and entities will be critical.</p>
<p>MAAC/Horakh</p>	<p>Reporting should be on a "delay" basis. Known delays to the plan should be reported, along with the reason for the delay and use of alternate solutions.</p>
<p>MAAC/Kuras</p>	<p>A plan is a plan at that point in time. Plans change. Periodic checks of implementation of plans can uncover these plan changes that should be allowed.</p>
<p>NYSRC</p>	<p>Updated transmission plans should be reported along with compliance assessments as required.</p>
<p>R. Snow</p>	<p>When there is a significant change in the assumptions, the plan needs to be re-studied and revised as appropriate. The SAR must require such re-studies. Any plan is only as good as its assumptions. Whenever there is a significant change in the assumptions, the plan needs to be revised to account for the change. Having a plan that assumes there will be specific generation projects is worthless when those specific projects are changed, canceled or if other generation retires.</p>
<p>SPP</p>	<p>Although SPP is implementing a 2 year planning cycle, project updates are collected on an annual basis. To ensure compliance with reliability criteria, mitigation reviews are also provided on an annual basis consistent with the annual model building process. Updates due to new "out of cycle" projects or significant scope/timing changes associated with major projects in the approved regional expansion plan and its assessments are evaluated on an as-needed basis. Coordinated planning and model building using consistent definitions with neighboring regions/entities will be critical. Efforts should be undertaken to put data collection, modeling building and transmission assessment processes for neighboring regions/entities on the same cycles.</p>
<p>WESTAR</p>	<p>In the annual process to update power flow models, there are necessarily changes to the load forecast, use of the interconnected network, and financial constraints which must be taken into account. Reporting to the Regional Reliability Organization should include a discussion of substantive changes and reasons behind them. There should not be a judgment made by the RRO that the explanation is "adequate" so long as the explanation is made. The changes are critical information that must be taken into account when evaluating transmission service requests. Reporting should not be more frequent than the model-building cycle.</p>

QUESTION 4: SHOULD THE REQUIREMENT TO CONSIDER PLANNED OUTAGES IN ADDITION TO EACH CONTINGENCY REMAIN PART OF THIS PLANNING STANDARD?

Question in its entirety:

4. Existing Planning Standard I.A requires: "The systems must be capable of meeting Category C requirements while accommodating the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed".

The SAR drafting team believes that it is impractical to exhaustively test for every contingency described in each category plus every conceivable planned outage. Should the requirement to consider planned outages in addition to each Category A through D contingency remain part of this planning standard?

- (1) Yes, consider planned outages in all Categories A through D.
- (2) Yes, consider planned outages in some Categories only – Please specify which Categories.
- (3) No, do not consider planned outages in addition to each contingency in any Category.

SUMMARY:

Entities supporting Choice (1) 6 (16 individuals)

Entities supporting Choice (2) 15 (76 individuals)

Entities supporting Choice (3) 8 (27 individuals)

Miscellaneous Comment (No choice selected) – 1 entity (2 individuals) - Seminole

Consideration by the SAR DT:

The SAR Drafting Team believes there is confusion surrounding the planned outage requirement in Table I of the existing standard. The SAR DT is recommending that the new Planning Standard clarify the issue of how a planned outage should be used in a planning assessment.

The new Standard should specify whether the planned outage requirement should be retained for Categories B and C. If retained, the requirement should be clarified in such a way that it can be practically implemented. In particular, the Transmission Planner should not be required to exhaustively test their systems for every conceivable planned (including maintenance) outage in addition to every conceivable Category B and C contingency.

The new Standard should clarify that the planned outage requirement does not apply to Categories A and D.

Entities supporting Choice (1) – consider planned outages in ALL Categories A through D.

ERCOT, ISO/RTO, NYSRC, MAAC/Kuras, TVA (half of group), WESTAR (6 entities, 16 individuals)

ENTITIES SUPPORTING CHOICE (1) – CONSIDER PLANNED OUTAGES IN <u>ALL</u> CATEGORIES A THROUGH D	
ERCOT, ISO/RTO, NYSRC	Again, the existing standards should not be weakened.

MAAC/Kuras	Contingencies don't only happen when all lines are in service. Outages should be modeled during all types of contingency evaluation. This may be a fairly daunting task but this evaluation will help the system operators be prepared for the reality of operating the system in a less than ideal state. Possible ways to select lines to outage may be to look at lines with high unscheduled outage rates, lines close to sources of contamination, lines through areas that have historically had vegetation contact problems, and especially lines that when outaged can cause operating problems.
TVA	{Half of group} . Everyone in the group agreed that planned outages should be considered, but the group didn't agree on which categories to apply. About half believed they should be applied to all categories while the other half believed only A and B categories should have planned outages studied for the one year and beyond horizon.
WESTAR	The notion of including maintenance outages is to ensure that system restorations correctly evaluate single elements that would be removed in groups under a breaker-to-breaker outage analysis. The intent should not be to have any single element out for maintenance AND withstand the next contingency and should be stated as such.

Entities supporting Choice (2) – consider planned outages in SOME Categories only.

AEP, AESO, ALLEGHENY, CWLP, ENTERGY, IMO, ISONE, MAAC/Horakh, NPCC, R. Snow, SCGEM, SERC, SOUTHERNCO, SPP, TVA (half of group), WECC (WECC-1 plus WECC-2). (15 entities, 76 individuals)

ENTITIES SUPPORTING CHOICE (2) – CONSIDER PLANNED OUTAGES IN <u>SOME</u> CATEGORIES.	
AEP	{B, C & D only} . For Categories where planned maintenance is considered, it should only be necessary to test the most significant planned outages, not all possible planned outages.
AESO	{A, B & C only} . There is a need to clarify what constitutes the "normal" condition when a facility (transmission or generation) is on a long duration planned outage (is it a day, a week, etc). The A to C contingency categories can then be applied to the "normal" condition as defined. The testing requirement could perhaps be stated in a way that leaves it to the judgment of the Planning Authority as to the critical combinations of outages that need to be tested.
ALLEGHENY	{A & B only} . Allegheny Power feels that it is practical to consider planned outages in categories A and B.
CWLP	{B and some C} . No further comments.
ENTERGY	{B & C only} . It is not necessary to include planned maintenance outages in addition to Category A (no contingencies) because Category A plus planned outages equals Category B (single contingency). Therefore inclusion of maintenance outages in Category A is superfluous. The current standards do not require planned outages with Category A for that very reason. Maintenance outages should be considered for only Category B and C contingencies. Category D recognizes that cascading will occur in conjunction with the contingencies, so adding on more planned outages seems unnecessary,

Consideration of Comments on SAR Version 2 of Standard 500: "Assess Transmission Future Needs and Develop Transmission Plans", posted for public comment May 5 – June 5, 2004.

	especially since Category D outages are very low probability events.
IMO, ISONE, NPCC	<p>{A, B & C only}. We reiterate that the existing standards should not be weakened and request that the SAR be clarified to remove ambiguity regarding what is meant by "considering" a planned outage. Planned outages at present are considered however this is deemed an Operational Planning issue and is conducted so as to set Operational Limits for those conditions on a pre-contingency basis to allow for N-1 conditions.</p> <p>This particular SAR will ultimately result in a "planning" Reliability Standard. The wording, as it has been phrased, infers that the system must be planned, designed and built to N-2 standards (i.e. a line out for maintenance on top of a circuit element outage). Treatment of planned outages should be considered to some extent and the listed entities suggest the drafting team receive direction from the SAC regarding planned outages. The listed entities suggest that planned outages should be considered only in categories in A through C.</p>
MAAC/Horakh	<p>{A & B only}. Consider planned outages in Categories A & B only, since these categories are high probability and therefore could easily occur during a planned outage.</p>
R.Snow	<p>{A, B & C only}. Categories A through C should be considered. Category D does not require action so the analysis with outages does not add anything. Most planning software allows the use of scripts to run multiple analysis without intervention. The state of modern computers is such that the added testing is not significant. Also, for most systems, this type of analysis is performed to define which load levels and generation dispatch would allow the maintenance (the problem in reverse).</p>
SCGEM, SOUTHERNCO	<p>{A & B only}. The requirement to consider planned outages in addition to each Category A and B contingency should remain part of this planning standard. We agree with the SAR drafting team that exhaustive testing for every contingency described and every load level in each category is not practical.</p>
SERC	<p>{A & B only}. The SERC PSS agrees that the requirement to consider planned outages in addition to each Category A and B contingency remain part of this planning standard. The SERC PSS could not reach consensus on the requirement to consider planned outages in addition to each Category C and D contingency. However, the SERC PSS does agree that exhaustive testing for every contingency described in each category is not required. The I.A compliance templates state that they must <i>"Be performed and evaluated only for those Category [B, C, and D] contingencies that would produce the more severe system results or impacts."</i></p>
SPP	<p>{B & C only}. C.3. needs to be modified to address N-1-1 concerns. Category B (B1, B2, B3 or B4, including loss of an element without a fault) or in the alternative create Category B5 to Loss of an element without a fault. The latter is preferred.</p> <p><i>[See similar comments - KCPL comment under Question 4 Choice (3) below, and Westar comment under Question 1(a) above]</i></p> <p>Planned outages are typically not evaluated more than one year in advance and are not scheduled during peak load conditions. However, the existing Planning Standard 1.A is problematic in that it requires the system to be designed to accommodate planned outages during peak load conditions.</p>
TVA	<p>{A & B only – half of group}. Everyone in the group agreed that planned</p>

	outages should be considered, but the group didn't agree on which categories to apply. About half believed they should be applied to all categories while the other half believed only A and B categories should have planned outages studied for the one year and beyond horizon.
WECC-1 & WECC-2	{A, B & C (except C-3)} . All contingencies where a single point of failure could cause facilities to be lost should be tested for compliance with the standards even under planned maintenance conditions. However, it should never be necessary to exhaustively test every possible combination of outages. Those contingencies that are clearly not critical outages should not have to be simulated.

Entities supporting Choice (3) – do NOT consider planned outages in addition to each contingency in any Category.

AES, AMEREN, ATC, BPA, DUKE, KCPL, MAPP, MEC (8 entities, 27 individuals)

ENTITIES SUPPORTING CHOICE (3) – DO NOT CONSIDER PLANNED OUTAGES IN ADDITION TO EACH CONTINGENCY IN ANY CATEGORY.	
AES	I would modify C-3 since it has the same effect as or similar to a C-3 event to include (line out followed by a category B event).
AMEREN	<p>Is the issue planning the system or granting the outage? Local load may be exposed for granting a maintenance/construction outage, but the system should not be at risk. If the system is planned with category C requirements, in most cases it should meet category A and B requirements during a planned outage. To meet requirements of categories A and B during planned outage should be adequate.</p> <p>Planned outages for maintenance or construction are generally managed in the operating horizon, and are granted only during specific load levels (off-peak), generation patterns, and interchange patterns when the transmission system is not expected to be fully utilized.</p> <p>We agree that clarification should be provided on how this information should be used in an assessment. However, as the scope of planning assessments is for the planning horizon of one year or more (SAR-4, paragraph 2) and not the operating horizon, we do not believe that the requirement for planning for maintenance outages should be included in planning assessments.</p>
ATC	Planning the system should consider the need for planned outages but should not require the capability to plan outages at peak system loads.
BPA	This requirement should be addressed in operational planning studies (less than one year). This standard is not appropriate for Transmission Planning studies except possibly as a tool to measure or compare the robustness or availability of transmission plans. This is not an item that should require any compliance action.
DUKE	<p>The first priority should be to clarify the requirements of the I.A table. Utilities/ regions are interpreting the table differently. What was the original basis for the contingency categories and required response in the table? Clarify whether the original intent was to perform thermal, voltage and stability screens for all categories and the frequency at which the screenings were intended to be performed.</p> <p>It is impractical to expect all screenings of all categories on a frequent basis. It may be appropriate to state that the table is for general guidance and that</p>

	transmission owners may determine frequency at which studies should be performed based on load growth, system loading and significance of changes to the system.
KCPL	<p>Planned outages are typically short-term (less than 1 year) and should be considered in the operating horizon. A planned outage is typically allowed during system load conditions when they will have minimal impact on the system.</p> <p>KCPL would prefer to clarify the existing Category B contingency that states "Loss of an element without a fault" be listed as the B5 contingency on the Table. Then, in Category C under Contingency 3, the revised wording should read "3. Category B (B1, B2, B3, B4, or B5) contingency, manual system adjustments, followed by another Category B (B1, B2, B3, B4, or B5) contingency. This will allow for the first contingency to include a planned outage (B5 without a fault) as well as a contingency with one of the fault conditions described in B1, B2, B3, and B4.</p> <p>{See similar comments - Westar comment under Question 1(a) and SPP comment under Question 4, Choice (2).}</p>
MAPP & MECC	<p>Planned Outages can be scheduled and analyzed in advance in the operating horizon (less than one year). Therefore, it should not be necessary to require that "systems must be capable of meeting Category C requirements while accommodating the planned outage of any bulk electric equipment..."</p> <p>Planned outages should be studied in advance by the requesting control area and be reviewed by the governing Reliability Coordinator to determine if overloads could occur. If studies show that overloads could occur, the planned outage should be deferred or operating guides prepared which would be used in the event a contingency does occur.</p>
MEC	There is no need to plan or build facilities to meet Planning Standard 1.A when Planned Outages can be accommodated within the frame work of existing guidelines and procedures. Studies conducted for the operating horizon are not the subject of this standard.

MISCELLANEOUS COMMENT ON CONSIDERING PLANNED OUTAGES – (No Choice Selected)	
SEMINOLE	Many grid operations difficulties occur when a line is scheduled out for maintenance. If this SAR is going to address required N-2 planning assessments, then it must be clear and specific regarding the conditions when N-2 assessments are appropriate and the specific criteria for N-2 assessments.

QUESTION 5: ARE YOU AWARE OF ANY REGIONAL OR INTERCONNECTION DIFFERENCES IN REQUIREMENTS FOR ASSESSING AND PLANNING TRANSMISSION SYSTEMS IN NORTH AMERICA?

Question in its entirety:

5. Are you aware of any Regional or Interconnection differences in the requirements for assessing and planning transmission systems in North America? If so, please list and explain.

SUMMARY: 10 entities (68 individuals) responded to this question and gave examples of Regional/Interconnection differences.

Consideration by the SAR DT:

The SAR Drafting Team considered each comment individually, as shown in the table below.

Entities responding to Question 5 – are you aware of any Regional/Interconnection differences?

BPA, CWLP, KCPL, NYSRC, SCGEM, SEMINOLE, SOUTHERNCO, SPP, R, Snow, WECC (WECC-1 plus WECC-2), WESTAR. (10 entities, 68 individuals)

ENTITIES RESPONDING TO QUESTION (5) – ARE YOU AWARE OF ANY REGIONAL/INTERCONNECTION DIFFERENCES?	
BPA	<p>Although WECC has several requirements in its standards that are more stringent than the existing NERC criteria, it also has two standards that are less stringent (C2 and C9). Depending on the resolution of question #1 above, C2 and C9 may be a regional difference.</p> <p>WECC has a formal Probabilistic Planning process that allows adjustment of performance levels of contingencies in either direction. As this SAR states that the existing NERC Table I is the minimum criteria for probabilistic methods, this will be a regional difference for WECC. This is discussed more in our comments on the SAR document.</p> <p>Consideration by the SAR DT</p> <p><i>The present SAR no longer states that existing Table I is the minimum criteria for probabilistic methods, only that Table I should be used as a <u>starting point</u> for a review of the existing standard. Thus, probabilistic planning could allow for adjustment of performance requirements in either direction.</i></p> <p><i>The SAR DT is recommending that the review of the existing standard include the likelihood, duration and impact of events, as well as the definition of applicable ratings (A/R). This review may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.</i></p> <p><i>Since there was no clear consensus on how to address re-classification of events, the SAR DT feels that a thorough review of existing Table I will assure that events are properly classified for the new Standard.</i></p> <p><i>If differences in the classification of events or performance requirements remain after the draft Standard is posted, please provide your specific</i></p>

Consideration of Comments on SAR Version 2 of Standard 500: "Assess Transmission Future Needs and Develop Transmission Plans", posted for public comment May 5 – June 5, 2004.

	<i>comments at that time</i>
CWLP	<p>WECC has asked the NERC PC for waivers for some of the Category C requirements.</p> <p>Consideration by the SAR DT <i>See the SAR DT response to WECC-1 & WECC-2 in this table.</i></p>
KCPL	<p>KCPL is aware of neighboring regional council differences in classification of Category B and C contingencies between SPP and MAPP.</p> <p>Consideration by the SAR DT <i>The SAR DT is recommending a review of existing Table I, which may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.</i></p> <p><i>Since there was no clear consensus on how to address re-classification of events, the SAR DT feels that a thorough review of existing Table I will assure that events are properly classified for the new Standard.</i></p> <p><i>If differences in the classification of Category B and C contingencies remain after the draft Standard is posted, please provide your specific comments at that time.</i></p>
NYSRC	<p>It is the NYSRC's position that (1) NERC specifies minimum standards, (2) a Region may establish more stringent standards for its members separate from the NERC standards, and (3) it is unnecessary to include these more stringent standards within the framework of the NERC standards.</p> <p>Consideration by the SAR DT <i>The SAR DT agrees with this position.</i></p>
SCGEM, SOUTHERNCO	<p>Not aware of any at this time. However, Regional Differences could develop and each request for a Regional Difference should be considered individually.</p> <p>Consideration by the SAR DT <i>The SAR DT agrees with this position.</i></p>
SEMINOLE	<p>In Florida, with the state requirements for the siting of facilities, the planning horizon should be adjusted from 5 YRS to 8 YRS. The 5 YR horizon is too short for some major transmission line projects and/or studies of transmission interconnections/upgrades for base load central station generating facilities.</p> <p>Consideration by the SAR DT <i>The present SAR provides for a planning horizon of 5 years <u>or more</u>.</i></p>
SPP	<p>SPP is aware of differences between SPP and the neighboring regions of ERCOT, MAPP and WECC.</p> <p>Consideration by the SAR DT <i>If differences remain after the draft Standard is posted, please provide your specific comments at that time.</i></p>
R. Snow	Each region has their own requirements.

	<p>Consideration by the SAR DT</p> <p><i>Each Region has the right to request Regional differences for approval as part of the Standard.</i></p>
WECC-1 & WECC-2	<p>The existing NERC Standard C-9 (and C-2 for bus sectionalizing breakers) as it applies to WECC should be modified so that thermal limit and voltage limit violations are allowed for bus sectionalizing breaker failures. This is because bus sectionalizing breaker failure is a relatively low probability event. Use of a bus sectionalizing breaker should be encouraged because it reduces the impact of a disturbance to a portion of the load only. Without the proposed modification there is no incentive to use the sectionalizing breaker. However, under no conditions should system instability or cascading outages be allowed for bus sectionalizing breaker failures.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending a review of existing Table I, including the likelihood, duration and impact of events, as well as the definition of applicable ratings (A/R). This review may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.</i></p> <p><i>Since there was no clear consensus on how to address re-classification of events, the SAR DT feels that a thorough review of existing Table I will assure that events are properly classified for the new Standard.</i></p> <p><i>If differences in the classification of events or performance requirements remain after the draft Standard is posted, please provide your specific comments at that time.</i></p>
WESTAR	<p>Yes. MAPP categorizes some contingencies differently.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending a review of existing Table I, which may result in a re-classification of Table I events for the new Standard. The review may also result in other changes, such as addition or deletion of categories, events or performance requirements, use of probabilistic planning methods, or re-naming of categories based on event probability ranges.</i></p> <p><i>Since there was no clear consensus on how to address re-classification of events, the SAR DT feels that a thorough review of existing Table I will assure that events are properly classified for the new Standard.</i></p> <p><i>If differences in the categorization of events remain after the draft Standard is posted, please provide your specific comments at that time.</i></p>

QUESTION 6: DO YOU HAVE ANY OTHER COMMENTS ON THE SAR (V2)?

Question in its entirety:

6. Do you have any other comments on Version 2 of the SAR? Please list and explain.

SUMMARY: Most of the 28 entities (121 individuals) responded to this question and provided additional comments on the SAR (Version 2).

Consideration by the SAR DT:

The SAR Drafting Team considered each comment individually, as shown in the tables below.

The additional comments were divided into the following headings:

- *General – Is there a need for this SAR? How will this SAR fit in with the new Version 0 Standards? Will the existing standards be weakened?*
- *Scope of Standard*
- *Planning Horizon*
- *Use of Operating Procedures*
- *Transition Between Operating & Planning Standards*
- *Functions to Which the Standard Applies*
- *Applicable Portions of Existing Standards*
- *System Models*
- *Resource Planning*
- *Use of Generation or Load as Solutions*
- *Formatting of the SAR*
- *Demand Levels for Modeling*
- *Definition of Terms*
- *Variability of Load & Generation*
- *Probabilistic Planning Methods*
- *Planned Outages*
- *Applicable Ratings*
- *Short Circuit Current*
- *Other Areas that Should be Added or Clarified*

GENERAL COMMENTS ON THE SAR (VERSION 2)

<p>ATC</p>	<p>The SAR drafting team seems to have its arms around the issues and seems ready to proceed to Standard development.</p> <p>Consideration by the SAR DT <i>The SAR DT agrees with this position and appreciates the vote of confidence.</i></p> <p>On p. 3 of the SAR, Market Interface Principles, Question 5 stating that the Standard will not require public disclosure of commercially sensitive information:</p> <p>Depending on the level of public exposure of the load flow and stability models, generation cost data and stability parameter data may be deemed by some entities as confidential market information.</p> <p>Consideration by the SAR DT <i>This SAR does not establish the level of public exposure of data. The Standard Drafting Team will determine these requirements. Please submit your comments at the time of the draft Standard posting.</i></p>
<p>IMO, ISONE, NPCC</p>	<p>The entities listed believe that the relationship between the concept of the Version 0 Standards and all the developing Version 1 Standards needs to be consistent. The reliability attributes of the Version 0 standards must be "carried through and into" the Version 1 Standards and there needs to be coordination to ensure this occurs.</p> <p>Consideration by the SAR DT <i>There will certainly be changes between V0 and the developing V1 Standards (V1 will be a revision of V0) but these changes must be approved by the industry, thus assuring carry-through and acceptance of reliability attributes.</i></p>
<p>IMO, ISONE, NPCC, NYSRC</p>	<p>It is the opinion of NYSRC, ISONE, IMO, and the Northeast Power Coordinating Council's CP9 working group participating members that the existing NERC criteria should not be weakened, including the NERC Planning Standards listed in the SAR as the starting point to be used in drafting a new standard. Our comments support our position that the existing Planning Standards should not be weakened.</p> <p>Consideration by the SAR DT <i>The majority of industry comments have indicated that this SAR is needed to consider content changes in existing Standards. There will be changes between the Version 0 standards (existing standards with formatting changes) and the developing Version 1 standards (V1 will be a revision of V0), but these changes must be approved by the Industry.</i></p> <p><i>All parties will have an opportunity to participate in the Standard drafting process, including commenting on the draft Standard. Concerns that changes made may weaken the Standard should be brought up at that time.</i></p>
<p>NYSRC</p>	<p><u>With the advent of the Version 0 standards, we believe that there is no longer a need for this SAR.</u> The comments in the "Consideration of Industry Comments" paper indicate that comments received in 2002 on SAR Version 1 were in favor of a standard on transmission assessment and planning, which was the SAR DT's reason for preparing this SAR. However, the Version 0</p>

	<p>standards development process will now provide a transmission planning standard, without requiring the preparation of this new SAR.</p> <p>Despite this position, if the DT does get sufficient support to go forward with a new standard, NYSRC has additional comments, as shown below.</p> <p>Consideration by the SAR DT</p> <p><i>Version 0 Standards are intended to re-format the existing Standards <u>without changing content</u>, using Functional Model terminology. The majority of industry comments have indicated that this SAR is indeed required to consider content changes in existing Standards.</i></p> <p>The relationship with the Version 0 standards should be recognized in the SAR, including the mechanism of how this "Version 1" standard would replace Version 0.</p> <p>Consideration by the SAR DT</p> <p><i>Version 0 Standards are intended to re-format existing Standards without changing content, using Functional Model terminology. The present SAR uses these existing approved Standards as a starting point to consider content changes for a new Planning Standard. There will be changes between V0 and the developing V1 standards (V1 will be a revision of V0), but these changes must be approved by the Industry.</i></p>
SPP	<p>Implementation of this SAR needs to be coordinated with the activities of the Version 0 Standards Drafting Team.</p> <p>Consideration by the SAR DT</p> <p><i>See our response to NYSRC above.</i></p>
WESTAR	<p>How will this SAR integrate with Version 0 Standards?</p> <p>Consideration by the SAR DT</p> <p><i>Version 0 Standards are intended to re-format the existing Standards without changing content, using Functional Model terminology. The present SAR uses these existing approved Standards as a starting point to consider content changes for a new Planning Standard.</i></p>

COMMENTS ON SCOPE OF STANDARD

AESO	<p>The SAR drafting team should clarify through rules, tests, definitions, etc. the portion of an entity's transmission system that shall be planned under the full NERC Standard and what portion may be exempted.</p> <p>Consideration by the SAR DT</p> <p><i>All NERC Standards apply to the bulk electric power system.</i></p> <p><i>The SAR DT felt that the definition of "bulk transmission" is an issue too large to be handled by one DT alone, and should be defined at a higher level. Accordingly, the SAR DT referred this issue to the NERC Director of Standards.</i></p>
IMO, ISO/RTO	<p>This standard should make it abundantly clear that it applies to both internal and external systems, that is the system under study and adjacent systems, or the entire interconnection if appropriate.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT agrees with this position. If the commenter believes the Standard does not sufficiently address this issue, we encourage the commenter to provide specific language to address this concern when a draft Standard is posted.</i></p>
SEMINOLE	<p>The SAR should require joint transmission planning - at a minimum, joint transmission planning should be required between transmission service providers and their network service customers.</p> <p>Consideration by the SAR DT</p> <p><i>Based on industry feedback to the first posting (V1) of the SAR, this present SAR indicates the Standard will identify reliability performance requirements, but not specify <u>how</u> to achieve such requirements. Joint planning is one way to achieve the reliability requirements, and is neither precluded nor required by this SAR.</i></p>

COMMENTS ON THE PLANNING HORIZON

ALLEGHENY	<p>This paragraph and the next (<u>the 2nd & 3rd paragraphs of posted SAR-Version 2</u>) are unclear and appear to be conflicting. This first paragraphs specifies that the "scope of such assessments and plans is for a planning horizon of one year or more". The next paragraph specifies, "Assessments should cover a planning horizon of at least 5 years". This appears to be a conflict. It may be that the term "planning horizon" is being used differently in these two paragraphs. It is unclear to us what is the intention of the first of these two paragraphs.</p> <p>Consideration by the SAR DT</p> <p><i>As a result of your comment, the present SAR has been clarified to indicate that the planning period starts at one year and extends to 5 years or more.</i></p>
NYSRC	<p>From SAR Version 2: ".....The planning horizon must be long enough to permit timely implementation of viable solutions to remedy the potential inadequacies found. Assessments should cover a planning horizon of at least 5 years. The horizon may be longer than 5 years, based on regulatory or legislative requirements, or on the judgment of the Transmission Planner or Planning Authority....."</p> <p>In paragraph above, 2nd sentence, insert "and plans" after "Assessments". The last sentence is not needed. A Region or other entity may have more stringent requirements than NERC – therefore, such a statement is not needed.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT agrees and accepts your first comment for inclusion in the revised SAR. The SAR DT decided to retain the last sentence in the referenced paragraph to clarify the requirement about the planning horizon.</i></p>
R. Snow	<p>While some of the information about generation additions and load growth are considered reliable for five (5) years, a long-term study of approximately ten (10) years is necessary to identify global issues such as import limitations to a region that would require projects that have traditionally taken more than five (5) years.</p> <p>Suggest the following wording: "Assessments shall cover a detailed planning horizon consistent with available information but no less than five (5) years. The five year horizon shall include load growth, new internal and external firm generation, generation retirements/failures, uncontrollable loop flows, reliance on external generation (identify both firm and market), topology changes, and firm transactions. A longer term study using a variety of scenarios that are expected to cover the most likely long term activity, shall be conducted to identify projects that take longer than five years to implement."</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT considered your alternative wording to be overly prescriptive. However, in the present SAR, the wording has been changed to clarify that the planning horizon extends to 5 years or more.</i></p>
SEMINOLE	<p>In Florida, with the state requirements for the siting of facilities, the planning horizon should be adjusted from 5 YRS to 8 YRS. The 5 YR horizon is too short for some major transmission line projects and/or studies of transmission interconnections/upgrades for base load central station generating facilities.</p> <p>Consideration by the SAR DT</p> <p><i>In the present SAR, the wording has been changed to clarify that the planning</i></p>

	<i>horizon extends to 5 years or more.</i>
--	--

COMMENTS ON USE OF OPERATING PROCEDURES

AMEREN	<p>"...there is no intent to exclude appropriate operating procedures...". What is "appropriate"? Could generation redispatch be an appropriate operating procedure? If yes, what level of redispatch is appropriate? The standard should include a definition of "appropriateness" of operating procedures so that they are developed and applied on a uniform and consistent basis.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes it to be problematic to produce an exhaustive list of all appropriate operating procedures. Furthermore, industry feedback to the first posting (V1) of the SAR indicated a strong industry preference for the Standard <u>not</u> to specify how to achieve the reliability requirements. However, if you believe the draft Standard, when posted, does not sufficiently address this issue, please submit your comments at that time.</i></p>
MAPP	<p>MAPP is concerned that the SAR does not limit manual or automatic readjustments for certain lower probability or low consequence events. MAPP urges that the SAR drafting team add additional provisions to require the drafting team to consider which manual and automatic readjustments are allowed and when in meeting the criteria that is included in the standards.</p> <p>Consideration by the SAR DT</p> <p><i>See the SAR DT response to AMEREN, above.</i></p>
R. Snow	<p>From SAR Version 2: ".....While the planning horizon is intended to provide for facility additions, there is no intent to exclude appropriate operating procedures from the transmission plan....."</p> <p>Replace this sentence with "The planning horizon is intended to provide for facility additions. Operating procedures shall not be used as a substitute for good system design and shall only be applicable during maintenance outages and while facilities are being constructed."</p> <p><i>[The original language would allow what was identified as the root cause of the Italian blackout. Namely, an operating procedure that had to be executed within 15 minutes. The operator had to call another area and ask them to perform an operating procedure. The procedure was underway but did not happen fast enough to avoid the next line trip. Operating procedures should never be a long term substitute for constructing facilities needed to assure reliability.]</i></p> <p>Consideration by the SAR DT</p> <p><i>Industry feedback to the first posting (V1) of the SAR indicated a strong industry preference for the Standard <u>not</u> to specify <u>how</u> to achieve the reliability requirements. Therefore, the SAR DT did not accept your suggestion. However, when the draft Standard is posted, feel free to submit your comments at that time.</i></p>

COMMENTS ON TRANSITION BETWEEN PLANNING & OPERATING STANDARDS

<p>BPA</p>	<p><i>Transition to Operating Standards:</i> The Planning Standards include multi-layered requirements for different types of outages, i.e., Level B single contingencies, Level C and D multiple contingencies. Compliance with these requirements is to be defined and monitored via the new Reliability Standards. However, once the system moves into the Operational timeframe (one year or less), Policy 2 presently requires meeting N-1 contingencies only with no requirements for Levels C and D. The transition between planning and operations needs further exploration.</p> <p>Consideration by the SAR DT</p> <p><i>As a result of your comment and others, the present SAR has been revised to require that the new Standard consider the transition between operating and planning standards. In particular, the new Planning Standard will be coordinated with other standards, such as Standard 600, "Determine Facility Ratings, Operating Limits and Transfer Capabilities", which also applies to operations.</i></p>
<p>MAPP & MEC</p>	<p>MAPP & MEC are concerned that the SAR does not provide for the coordination of the requirements of the planning standards in NERC Standard 500, "Assess Transmission Future Needs and Develop Transmission Plans", with the NERC Operating Standards provided in NERC Standard 600, "Determine Facility Ratings, Operating Limits, and Transfer Capabilities."</p> <p>The criteria that are proposed as a starting point for 500 in this SAR (events from Categories A through D) differ from the criteria that are included in the latest draft of NERC Standard 600 (Categories A and B). If these approaches are continued, then studies run for the operating horizon will differ significantly from studies run for the planning horizon.</p> <p>These differences in studies will carry over to the calculation of quantities used to offer transmission service, that is, Total Transfer Capacity and Available Transmission Capacity. If NERC does not coordinate these two standards, there will be a discontinuity in TTC and ATCs when the Planning Horizon begins and the Operating Horizon ends or from one day less than one year to one year. MAPP & MEC urge the SAR drafting team to consider this discontinuity and coordinate the SAR for 500 with the Standard that is being written for 600.</p> <p>If a discontinuity between criteria is allowed to continue in the SAR for Standard 500, the SAR drafting team should have a clear explanation for all market participants as to the reason for the discontinuity and how that should be dealt with by the elements of the NERC Functional Model.</p> <p>Consideration by the SAR DT</p> <p><i>See the SAR DT's response to BPA above.</i></p>

COMMENTS ON FUNCTIONS TO WHICH THE STANDARD APPLIES

<p>AMEREN</p>	<p>From SAR Version 2: ".....The Standard shall identify reliability requirements, but shall not specify how to achieve such requirements. These requirements shall apply to Transmission Planners and to Planning Authorities....."</p> <p>Should the requirements be applied to Transmission Owners also?</p> <p>Consideration by the SAR DT</p> <p><i>Yes. After reviewing your comment, we deleted the last sentence of the referenced paragraph, since page 2 of the SAR already lists TO as a function to which the Standard applies.</i></p>
<p>R. Snow</p>	<p>The standards should apply to Transmission Owners, Transmission Operators, Transmission Planners, anyone who is connecting facilities to the transmission system, control areas, and reliability coordinators.</p> <p>Consideration by the SAR DT</p> <p><i>After reviewing your comment, we deleted the last sentence of the referenced paragraph. On SAR page 2 is a list of functions to which the Standard applies. The functions listed are: RA, PA, TP, TO, LSE. This list is consistent with the Functional Model.</i></p>

COMMENTS ON APPLICABLE PORTIONS OF EXISTING STANDARD

<p>NYSRC</p>	<p><u>From SAR Version 2:</u> ".....The applicable portions of the following existing NERC Planning Standards will be used as the starting point in drafting these requirements:</p> <ul style="list-style-type: none"> • I.A Transmission Systems • I.B Reliability Assessment • I.D Voltage Support & Reactive Power • II.A System Data • II.D Actual and Forecast Demands....." <p>Define "applicable portion". List the specific standards and measurements that are intended to be used as the starting point.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes this level of specificity is not needed in a SAR. If this concern is not addressed in the posted draft Standard, please feel free to submit your comments at that time.</i></p>
<p>R. Snow</p>	<p><u>From SAR Version 2:</u> ".....The applicable portions of the following existing NERC Planning Standards will be used as the starting point in drafting these requirements:</p> <ul style="list-style-type: none"> • I.A Transmission Systems • I.B Reliability Assessment • I.D Voltage Support & Reactive Power • II.A System Data • II.D Actual and Forecast Demands....." <p>Add the following after the bullets. <i>"In addition to the above, the standard shall provide requirements on methodology of forecasting and normalizing load. This would include methods of determining the normalized load over a large geographic area with different weather patterns and norms. The "normalized" load should not be the load associated with the median weather over a summer or winter period but the load level that will provide sufficient reliability to supply all firm load obligations. Each region shall provide a definition as to what is sufficient reliability. The definition shall clearly define the risk that is being assumed in terms similar to the LOLE for lack of generation. In addition to the above two risk variables, a methodology shall be identified to quantify the risk of not being able to deliver the difference between the local load and generation. This is essentially the ability of the transmission system to respond to different generation dispatch patterns."</i></p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes this level of specificity is not needed in a SAR. If these concerns are not addressed in the posted draft Standard, please feel free to submit your comments at that time.</i></p>
<p>SCGEM</p>	<p>It would also be beneficial to the generation sector if the SDT for this new Planning Standard could summarize the differences between the existing Planning Standards I.A, I.B, I.D, II.A, and II.D and the new Planning Standard as it is being developed. This would gauge the potential impact to the plants. The main concerns have been 1) how to address regional differences (primarily related to Category C events), 2) how to differentiate Table I's application to the Planning world versus the Operations world, and 3) how to state the requirements more clearly.</p> <p>Consideration by the SAR DT</p> <p><i>Since the revised Standard has not yet been drafted, the summary you</i></p>

	<p><i>requested cannot be provided at this time. This summary comparison will be addressed in the Implementation Document that accompanies the new Standard.</i></p>
SEMINOLE	<p>The SAR should define specific planning voltage criteria for consistency between transmission owners/providers. Voltage Criteria should be specifically defined for normal condition and N-1 conditions and can be specified differently for:</p> <ul style="list-style-type: none">• Bulk power - non-load serving buses• Meshed/Looped - load serving buses• Radial - load serving buses <p><i>Consideration by the SAR DT</i></p> <p><i>The SAR DT believes this level of specificity is not needed in a SAR. If this concern is not addressed in the posted draft Standard, please feel free to submit your comments at that time.</i></p>

COMMENTS ON SYSTEM MODELS

<p>AESO</p>	<p>We believe that the assumptions made for the amount, type and location of future supply are important considerations in assessing the future needs of transmission systems. The SAR drafting team should consider this forecast requirement in developing this Standard. Similarly, there is difficulty in separating planning for reliability and planning for overall system efficiency and economy, and the Standard must be clear on this differentiation.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes the present SAR addresses most of these concerns. With regard to your last concern, the SAR DT believes there is not always a clear differentiation between reliability, efficiency & economy considerations. However, NERC standards primarily focus on reliability and do not directly address efficiency & economy considerations. If you have specific suggestions after the draft Standard is posted, please comment at that time.</i></p>
<p>AMEREN</p>	<p>We believe that for planning of robust transmission systems, the Standard should include (1) some incremental transfer capability requirement in addition to what is "projected" or modeled in the base case, (2) a combination of a line and a generator outage should be included in category B.</p> <p>Consideration by the SAR DT</p> <p><i>With regard to (1) the SAR requires each Planning Authority and Transmission Planner to document the methodology for incorporating planned generation assets in the model. In response to your comment, the present SAR has been revised to specify that the methodology for incorporating planned generation assets (including transfers) must be documented. However, the SAR DT believes any specific incremental transfer capability requirement in the new Standard would be overly prescriptive.</i></p> <p><i>With regard to (2), the Standard Drafting Team will be reviewing the likelihood, duration and impact of events, as well as performance requirements of the existing Table I Categories. If this issue is still a concern when the draft Standard is posted, please submit your comments at that time.</i></p>
<p>AMEREN</p>	<p>Why document and disclose methodologies limited to planned generation only? What about planned transmission and interchange? Is it because there is more uncertainty for speculative generation than transmission? What about differences in modeling details required for different type of analyses, such as thermal or voltage, regional or local? It is our experience that more detailed representation (lower voltage facilities) is required for voltage analysis than thermal analysis. Perhaps the standard should state that additional detail may need to be added to the model to adequately represent the system for specific studies.</p> <p>Consideration by the SAR DT</p> <p><i>In response to your comment, the present SAR has been revised to require documentation of modeling assumptions, including generation modeling assumptions. The SAR DT highlighted generation assumptions because the SAR DT believes such assumptions are particularly important. Furthermore, given unbundling of generation resources from transmission in some areas, we believe there is considerable additional uncertainty in these assumptions,</i></p>

	<p><i>both with regard to new generating units and dispatch of new and existing units.</i></p>
ATC	<p>New standard needs to consider the difficulties, particularly for stand-alone transmission companies, in obtaining resource information so models can balance load and resources.</p> <p>Consideration by the SAR DT</p> <p><i>The present SAR does indicate that the Standard shall require that system models be developed, maintained and shared in a manner consistent with the Functional Model. The SAR also states that the Standard shall consider a requirement for LSEs to provide forecast resource data for input to the models. If the commenter has specific suggestions to further address this concern, please provide specific suggestions when the draft Standard is posted.</i></p>
KCPL	<p>In regards to developing accurate regional models, all known firm transmission service, including rollover provisions for all firm transmission service, should be included in the base case models.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes this provision does not need to be in the SAR for the new Standard. Rollover provisions for firm transmission service is a FERC tariff issue that does not apply to entities outside of FERC's jurisdiction. Therefore, the SAR DT believes this provision would be overly prescriptive.</i></p>
MAPP	<p>MAPP is concerned that there is no reference in the SAR to the need to handle firm contracts that may roll-over in the futures. Plans developed for the transmission system must recognize that the transmission system must have sufficient capacity to handle roll-overs. MAPP urges the SAR drafting team to include an appropriate description of the requirement for the plans with regard to roll-overs.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes this provision does not need to be in the SAR for the new Standard. Rollover provisions for firm transmission service is a FERC tariff issue that does not apply to entities outside of FERC's jurisdiction. Therefore, the SAR DT believes this provision would be overly prescriptive.</i></p>
R. Snow	<p>From SAR Version 2: ".....The Standard shall require that system models be developed, maintained and shared in a manner consistent with the Functional Model. Included will be requirements that each Planning Authority and Transmission Planner document and disclose the methodology used for incorporating planned generation assets in the model, as well as how such generation is dispatched. While methodologies and assumptions must be documented, the Standard will not prescribe specific tools to be used in the performance assessment of the planned systems....."</p> <p>Replace the last sentence with "while the standard will not prescribe specific tools, it shall identify methodologies to validate and procedures to operate the tools so that the identified outcomes from the analysis are not dependent on the tool or the way the tool was used or initialized."</p> <p>Consideration by the SAR DT</p> <p><i>Industry feedback to the first posting (V1) of the SAR indicated a strong industry preference for the Standard not to specify how to achieve the</i></p>

	<p><i>reliability requirements. Therefore, the SAR DT did not accept your suggestion.</i></p>
<p>SCGEM, SOUTHERNCO</p>	<p>In relation to the methodology being used for incorporating planned generation assets in the model and how generation is dispatched: the type of each generating unit, the primary fuel type for each generating unit, and a dispatch order of the generating units should be required. In addition, a general description of the dispatch methodology used for the system should also be required. However, no cost information should be required.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The SAR DT believes the referenced language addresses this concern by requiring system model sharing and documentation of generation modeling assumptions. The SAR DT agrees with the commenter that cost data should not be required because it would violate Market Interface Principle 5 (see SAR p. 3) which prohibits requiring the public disclosure of commercially-sensitive information.</i></p>
<p>SEMINOLE</p>	<p>It is recommended that these models be "region-wide" system models that are developed utilizing a documented, consistent, region-wide criteria.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The SAR DT believes this provision would be overly prescriptive.</i></p>

COMMENTS ON RESOURCE PLANNING

DUKE	<p>Resource planning cannot be excluded from the standard. Guidance should be provided on incorporation of resource data from all LSE's and how resource deficiencies in outyear models should be handled (e.g. model fictitious generation with no reactive capability to ensure sufficient reactive resources are planned for if power is purchased from off system in the future). The increasingly frequent changes in resource designations are causing greater uncertainty in performance of planning for reliable system operation.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT agrees that generation resource modeling is an important data requirement for transmission assessment and planning. However, the SAR distinguishes resource information as an input to transmission planning studies from a requirement to assess and ensure the adequacy of generation resources (i.e., resource planning).</i></p> <p><i>The SAR DT believes it is an open issue as to what level of specificity the Standard should require for model building. If this issue is still a concern when the draft Standard is posted, please submit your comments at that time.</i></p> <p><i>Note: Whether to check the Resource Planning box on page. 2 of the SAR (as a function to which the Standard applies) has been deferred to the NERC Director of Standards.</i></p>
ENTERGY, SCGEM, SERC, SOUTHERNCO	<p>Entities agree the Standard should not address resource planning. However, the Standard should include requirements for the LSEs to provide forecast resource data required to develop power flow models as required in the current II.D Standards. Accordingly, this new Standard should also apply to LSEs. (Thus, entities believe the "LSE" box on p.2 of SAR should be checked as an applicable function).</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes commenters have raised a valid point. The SAR DT believes it is an open issue as to what level of specificity the Standard should require for model building. Therefore, the present SAR has been revised to indicate that the Standard shall consider a requirement for the Load Serving Entities to provide forecast resource data.</i></p> <p><i>Note: LSE box on page 2 of the SAR has also been checked.</i></p>
ENTERGY	<p>In addition, the Standard should require the Transmission Planner to document and describe the methodology used to plan the transmission system around the generation dispatch assumptions used by the Transmission Planner to meet the LSE load when and if the LSE provided resources do not equal the LSE provided load.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes it is an open issue as to what level of specificity the Standard should require for model building. If this issue is still a concern when the draft Standard is posted, please submit your comments at that time.</i></p>
IMO, ISONE, NPCC	<p>The entities listed recognize that Resource Planning is not covered in the proposed Standard because it is considered as being handled by market</p>

Consideration of Comments on SAR Version 2 of Standard 500: "Assess Transmission Future Needs and Develop Transmission Plans", posted for public comment May 5 – June 5, 2004.

	<p>mechanisms that are/will be in place or perhaps addressed in a separate standard. Therefore, we assume that the generation and load information required to perform the planning studies are provided as described in section II.A of the existing Planning Standards. If not, sections II.B, II.E and III of the existing Planning Standards should also be used as the starting point in drafting of the reliability requirements.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The SAR DT believes it is an open issue as to what level of specificity the Standard should require for model building. If this issue is still a concern when the draft Standard is posted, please submit your comments at that time.</i></p>
NYSRC	<p>We agree that a transmission planning standard should not include Resource Planning requirements. However, the NYSRC strongly believes that NERC should develop a separate Resource Planning Standard.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The Resource and Transmission Adequacy Task Force (RTATF) proposed and NERC accepted that a Resource Adequacy SAR should be developed.</i></p>
WECC-2	<p>In order to develop any meaningful standard, the resource part of the power system should be addressed by including standards for the modeling of existing resources, planned retirement of resources, and planned resources in the next 5 to 10 years time frame. This information will be necessary in order to assess whether future systems can or can not meet the reliability standards.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The SAR DT believes the present SAR as written addresses this concern. Specifically, the SAR requires the documentation and sharing of system models, including the methodology of incorporating planned generation assets in the model as well as how such generation is dispatched.</i></p>

COMMENT ON USE OF GENERATION OR LOAD AS SOLUTIONS

AMEREN	<p>If generation is considered in lieu of transmission reinforcement, the system must be able to withstand the loss of that generation plus another single contingency. The reason for this is that generation can be on or off due to economic and other factors after its installation, while transmission is almost always "on".</p> <p><i>Consideration by the SAR DT</i> <i>The SAR DT agrees with this position. The loss of a generating unit plus another single contingency is already an event against which transmission systems must be tested in the existing Standards, and the present SAR provides for the new Standard to use the existing Standards as a starting point. If this issue is still a concern when the draft Standard is posted, please submit your comments at that time.</i></p>
--------	---

COMMENT ON SAR FORMATTING

ALLEGHENY	<p><i>From SAR Version 2:</i> ".....While the Standard should start from and closely align with the existing Planning Standards I.A, .B, .D, II.A,.D, the system conditions to be studied or assessed may need to be better defined or clarified. For example, the Standard should clarify that the requirement to assess the performance at all demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with regionally-defined criteria....."</p> <p>This paragraph starting "While the Standard should start from..." has a problem with it's second sentence. The sentence "For example..." does not really apply to the first sentence. We recommend that this paragraph be changed as follows:</p> <p><i>"While the Standard should start from and closely align with the existing Planning Standards I.A, .B, .D, II.A,.D, the system conditions to be studied or assessed may need to be better defined or clarified.</i></p> <p><i>Examples of areas that should be considered for clarification in the Standard include:</i></p> <p><i>The Standard should clarify that the requirement to assess the performance at ALL demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with regionally-defined criteria.</i></p> <p><i>The Standard should provide a clearer definition of "cascading outages".*</i></p> <p><i>And so on".</i></p> <p><i>Consideration by the SAR DT</i></p> <p><i>In response to your comment, we have revised the SAR to reflect the new formatting.</i></p>
-----------	---

COMMENT ON DEMAND LEVELS FOR MODELING

SEMINOLE	<p><i>From SAR Version 2:</i> ".....For example, the Standard should clarify that the requirement to assess the performance at all demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with regionally-defined criteria....."</p> <p>Regarding " ... a representative sample covering critical operating conditions ..."</p> <p>It is recommended that this standard include specific requirements; such as, at what load levels and how many different load levels is intended by this part of the SAR. A suggestion would be 100% and 80%, and perhaps the 60% load level.</p> <p><i>Consideration by the SAR DT</i> <i>The SAR DT considered your suggestions for specific load levels to be overly prescriptive.</i></p>
----------	--

COMMENTS ON DEFINITION OF TERMS

AMEREN	<p>In addition to the definition of "cascading outages" , clarification is needed for identification of a cascading state. For example, we are not sure that assumption of some percent overload, say 125% of emergency rating, is a good proxy for cascading.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT agrees that a clearer definition of cascading outages (including what constitutes a cascading state) must be provided in the new Standard, and be fully coordinated with the definition in other new Standards. The present SAR has been revised accordingly.</i></p>
ERCOT, IMO, ISONE, ISO/RTO, NPCC	<p>All entities listed suggest that the definition for Cascading Outage be fully coordinated with the STDs 200 and 600.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT agrees with this position. The SAR DT believes a clearer definition of cascading outages must be provided in the new Standard, and be fully coordinated with the definition in other new Standards. The SAR has been revised accordingly.</i></p>
IMO, ISONE, NPCC	<p>NPCC has submitted a suggested definition of "cascading outage" in the comments for the last posting of STD 200, which is endorsed by the other entities listed:</p> <p style="padding-left: 40px;"><i>Cascading Outage- "The uncontrolled successive loss of Bulk Electric System elements that propagate beyond a defined area (Balancing Area's) boundaries."</i></p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT agrees that a clearer definition of cascading outages must be provided in the new Standard, and be fully coordinated with the definition in other new Standards. Your specific suggestion is inconsistent with the definition in the latest version of STD 600. Please provide additional comments and suggestions when the draft Standard is posted.</i></p>
IMO, ISONE, NPCC	<p>NPCC would also like to submit a proposed definition of Bulk Power System, as follows, and would like it to be considered as a "building block" for the NERC BES (Bulk Electric System) definition. The definition is endorsed by the other listed entities:</p> <p style="padding-left: 40px;"><i>Bulk Power System-BPS-(or BES in NERC documents) — "The interconnected electrical systems within northeastern North America comprising generation and transmission facilities on which faults or disturbances can have a significant adverse impact outside of the local area. In this context, local areas are determined by the Council members."</i></p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT feels that the definition of "bulk transmission" is an issue too large to be handled by one Drafting Team alone, and should be defined at a higher level. Accordingly, the SAR DT referred this issue to the NERC Director of Standards.</i></p>
NYSRC	<p>From SAR Version 2: ".....The Standard should provide a clearer definition of "cascading</p>

	<p>outages".....".</p> <p>Replace "provide" with "consider".</p> <p>Consideration by the SAR DT <i>The SAR DT retained the word "provide", since we believe a clearer definition of cascading outages must be provided in the new Standard, and be fully coordinated with the definition used in other developing Standards. The present SAR has been revised to require that definitions be coordinated and consistent with other Standards being drafted by NERC.</i></p>
SERC	<p>The SERC PSS agrees that the Standard should provide a clearer definition of "cascading outages." In addition the SERC PSS recommends that the Standard provide a clearer definition of what is meant by "system stable."</p> <p>Consideration by the SAR DT <i>The SAR DT agrees, and the SAR has been revised to recommend that the new Standard provide a clearer definition of "system stable".</i></p>
SCGEM, SOUTHERNCO	<p>In general, the NERC Standards need to have a common definition across the board for any definition used in a Standard. For example, the definition for "Cascading Outages" needs to be coordinated with the Standards Drafting Team (SDT) for the "Determine Facility Ratings, Operating Limits, and Transfer Capability" standard (STD 600).</p> <p>Consideration by the SAR DT <i>The SAR DT agrees with this position. The SAR DT believes a clearer definition of cascading outages must be provided in the new Standard, and be fully coordinated with the definition in other new Standards. The SAR has been revised accordingly.</i></p>
SCGEM, SOUTHERNCO	<p>Southern agrees that the Standard should provide a clearer definition of "cascading outages." We suggest that the following be considered:</p> <p><i>Cascading — "The uncontrolled successive loss of system elements triggered by contingencies which results in widespread electric service interruption 1) that drops 1000 MW of load or more or 2) that crosses control area boundaries."</i></p> <p>In addition, Southern recommends that the Standard provide a clearer definition of what is meant by "system stable." We suggest that the following be considered:</p> <p><i>System stable — "For Category A and B simulations, system stable means that no generating units pull out of synchronism. For Category C events, system stable means that if units pull out of synchronism, 1) the resulting impedance swings are not out into the transmission system and 2) the total amount of generation lost because of out-of-step tripping does not exceed the control area operating reserve level."</i></p> <p>Consideration by the SAR DT <i>The SAR DT will pass these suggested definitions along to the Standard Drafting Team for consideration.</i></p>

COMMENTS ON VARIABILITY OF GENERATION & LOAD

IMO, ISO/RTO	<p>Seasonal and weather related variability should be considered in studies.</p> <p>Consideration by the SAR DT <i>The SAR DT agrees with this position. We believe the present SAR as written takes into account seasonal and weather-related variations.</i></p>
MAPP	<p>MAPP is concerned that there is no provision for recognizing the variability of generation in the SAR. MAPP asks the SAR drafting team to add another bullet to the SAR which states, "The Standard should take into account the variability of generation due to factors such as weather and time of day."</p> <p>Consideration by the SAR DT <i>The SAR DT agrees with this position. We have not added a bullet to the SAR, but rather have revised the existing bullet to take your suggestion into account.</i></p>

COMMENTS ON PROBABILISTIC PLANNING METHODS

<p>AESO</p>	<p>The basis of probabilistic planning, in our view, is to make planning decisions based on the metrics, such frequency, duration and impact, derived from probabilistic assessments. This is usually difficult to do in planning the bulk portion of the transmission system, since outage events are rare but their impact is significant (like multiplying infinity and zero). The categorization of contingencies in Table 1 using outage frequency as a determinant is a step in applying probabilistic techniques in this Standard but it is not probabilistic planning in its true sense. The SAR development team should clarify what it intends with regard to "the use of probabilistic planning methods".</p> <p>Consideration by the SAR DT <i>In response to your comment, the SAR DT has revised the present SAR to clarify our intent with regard to probabilistic planning methods.</i></p>
<p>AMEREN</p>	<p>From SAR Version 2: ".....The Standard should allow for the development and use of probabilistic planning methods. The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A.. There should be NERC approval of acceptable levels of risk....."</p> <p>The second sentence about "The minimum requirements of probabilistic methods Does this mean that probability should be assigned to at least all of the contingencies included in Table I.A.?"</p> <p>AMEREN believes that defining acceptable levels of risk will be a major undertaking. Isn't the level of risk dependent upon the entity and/or perception? Using a deterministic methodology in the planning horizon for single contingency provides a margin to handle many multiple unplanned facility outages or unforeseen system conditions in the operating horizon.</p> <p>Consideration by the SAR DT <i>The SAR DT is recommending the continued use of deterministic criteria in the Standard, but is also recommending probabilistic planning methods as an alternative or augmentation to the deterministic criteria. The SAR DT believes probabilistic planning methods are another way of defining acceptable levels of risk. For example, the existing deterministic criteria considers all line outages to be the same level of risk, but a probabilistic method may differentiate transmission line outages by length of line. The SAR DT has revised the present SAR to clarify this point in response to your comment.</i></p>
<p>ATC</p>	<p>From SAR Version 2: ".....The Standard should allow for the development and use of probabilistic planning methods. The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A.. There should be NERC approval of acceptable levels of risk....."</p> <p>This may also go back to question 1 in the Comment Form, but the statement, "There should be NERC approval of acceptable levels of risk" needs to be better defined. For example does this mean that a utility can't decide to increase the operating temperature of a line conductor without NERC approval?</p> <p>Consideration by the SAR DT <i>The SAR DT agrees that the sentence concerning NERC approval was unclear. The SAR DT has removed the referenced sentence and added</i></p>

	<p><i>wording to clarify our intent regarding the "use of probabilistic planning methods".</i></p>
<p>BPA</p>	<p>The handling of probabilistic criteria in the SAR seems quite convoluted, i.e. it can only be used to <i>increase</i> performance levels AND has to be approved by NERC. This is not the way probabilistic planning should work.</p> <p>WECC presently has a process (Seven Step Reliability Performance Evaluation) to allow changes in performance requirements (both up and down) for specific outages based on rigorous analysis and monitoring actual performance. It is mostly applicable to requirements beyond the NERC criteria (such as outages of adjacent circuits on separate towers). Use of these methods should be allowed with approval of affected regions. This process should allow for movement below Table 1, i.e. moving Category C outage to Category D. One way to resolve this would be to replace the word "minimum" in the SAR to "starting".</p> <p>Consideration by the SAR DT</p> <p><i>In response to your comment, the SAR DT has added wording to clarify our intent regarding the "use of probabilistic planning methods". Specifically, there is no longer reference to "minimum criteria", but rather a recommendation that the existing Standards be used as a "starting point", allowing movement above or below existing Table I. The reference to NERC approval has also been removed.</i></p>
<p>NYSRC</p>	<p>Is the probabilistic method referred to here considered a replacement for the NERC Criteria or a supplement to NERC Criteria? NERC should not allow such a method as a substitute for NERC criteria. I am not aware that NERC has completed an analysis to evaluate and compare the level of reliability of probabilistic criteria with NERC criteria. Such an evaluation would be needed.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending the continued use of deterministic criteria in the Standard, but is also recommending probabilistic planning methods as an alternative or augmentation to the deterministic criteria. The SAR DT has revised the present SAR to clarify this point in response to your comment.</i></p>
<p>R. Snow</p>	<p>From SAR Version 2: ".....The Standard should allow for the development and use of probabilistic planning methods. The minimum requirements of probabilistic methods are the contingencies as described in Table 1 of existing Planning Standard I.A.. There should be NERC approval of acceptable levels of risk....."</p> <p>Add a sentence after the first sentence "The probabilistic methodology shall not ignore specific cases that would result in significant load dump or cascading outages. Each region shall identify how to resolve such outages." The last sentence "Acceptable levels of risk in terms of maximum consequential and programmatic load dump and maximum durations for the outages shall be defined."</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes this level of specificity is not needed in a SAR. However, the SAR DT appreciates your comment, and has revised the present SAR to clarify the potential application of probabilistic planning methods. If this issue is still a concern when the Standard is posted, feel free to submit your comments at that time.</i></p>

WECC-1	<p>It appears to us that as written, the standard that flows from this SAR can only allow the probabilistic planning methods to make the standard more, not less, stringent than the existing Standard IA. This is not the way probabilistic planning methods should work. This statement also does not make sense when you read the next sentence, "There should be NERC approval of acceptable levels of risk." If the standard can only be more stringent, then there is no need for NERC to approve the level of risk, or even the probability of occurrence of the contingency. One way to resolve this issue would be to change the word "minimum" to "starting".</p> <p>Consideration by the SAR DT</p> <p><i>In response to your comment, the SAR DT has added wording to clarify our intent regarding the "use of probabilistic planning methods". Specifically, there is no longer reference to "minimum criteria", but rather a recommendation that the existing Standards be used as a "starting point", allowing movement above or below existing Table I. The reference to NERC approval has also been removed.</i></p>
WECC-2	<p>The Standard should also allow for the use of Probabilistic Criteria. In WECC, Probabilistic Planning refers to the application of fixed planning standards to a given problem to determine the probable or expected load not served. Probabilistic Criteria is used to refer to adjusting the performance category based on the probability of the event for a specific facility. The performance category can move up or down depending on actual or planned performance. Therefore, Table 1 would be the starting point for making probabilistic criteria adjustments. Probabilistic adjusted criteria would be the basis for Probabilistic Planning.</p> <p>Consideration by the SAR DT</p> <p><i>See the SAR DT's response to WECC-1 and BPA above.</i></p>
WECC-1 & WECC-2	<p>The NERC Planning Standards should follow what WECC is doing with regard to listing disturbances as a guide, but say that other disturbances with the same probability should be included. List the probability ranges (outages per year), Category B: ≥ 0.33, Category C: 0.33 to 0.033; Category D1 (no cascading): 0.033 to .0033, Category D2: $< .0033$.</p> <p>The standard should allow for changes in the required performance for given disturbances if a probability in another range has been established for a given disturbance.</p> <p>NERC should require that the Regional Councils specify voltage dip and minimum frequency standards similar to WECC (i.e., the voltage dip and minimum frequency should be within Applicable Ratings). We are not proposing that NERC set fixed values for these standards that would be the same throughout the ten NERC Regions. NERC should not set the standards.</p> <p>WECC recommends that the approval of acceptable levels of risk be at the regional level.</p> <p>Consideration by the SAR DT</p> <p><i>In response to your comment, the SAR DT has added wording to clarify our intent regarding the "use of probabilistic planning methods".</i></p>

	<p><i>The SAR DT believes the existing Standard allows Regions to apply voltage dip and voltage stability Regional requirements under the "voltage limits" section of Table I. The SAR DT believes that frequency standards are outside the scope of Transmission Planning for most Regions, and has not included frequency standards in the NERC SAR. This does not preclude Regions where frequency standards have transmission adequacy implications from developing their own standards.</i></p>
--	--

COMMENTS ON PLANNED OUTAGES

AMEREN	<p>We do not believe that the requirement for planning for maintenance outages should be included in planning assessments. See AMEREN's response/comments to Question 4 in this document.</p> <p>Consideration by the SAR DT</p> <p><i>In reviewing industry responses, there was no clear consensus on the issue of including planned outages in planning assessments. See the SAR DT's response to MAPP below. We believe the revised wording in the present SAR adequately addresses these concerns.</i></p>
MAPP	<p>MAPP urges the SAR drafting team to add words under this bullet to more clearly explain the SAR drafting team's position with regard to prior planned outages.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT believes there is confusion surrounding the planned outage requirement in the existing standard. The SAR DT is recommending that the new Standard specify whether to retain this requirement for Categories B and C. If retained, the Standard should clarify the requirement in such a way that the requirement can be practically implemented.</i></p> <p><i>In particular, the SAR DT has revised the present SAR to clarify that transmission entities are not required to exhaustively test their systems for every conceivable planned (including maintenance) outage in addition to every conceivable Category B and C contingency. The SAR DT has also revised the SAR to delete the planned outage requirement for Categories A and D.</i></p>
MEC	<p>MEC urges the SAR drafting team to add the following words to this bullet to more clearly explain the SAR drafting team's position with regard to planned outages:</p> <p><i>"In particular, it is incorrect to have a requirement to exhaustively test for every contingency described in each category plus every conceivable planned outage.</i></p> <p><i>Planned Outages can be scheduled and analyzed in advance in the operating horizon (less than one year). Therefore, it should not be necessary to require that "systems must be capable of meeting Category C requirements while accommodating the planned outage of any bulk electric equipment..." Planned outages should be studied in advance by the requesting control area and be reviewed by the governing Reliability Coordinator to determine if overloads could occur. If studies show that overloads could occur, the planned outage should be deferred or operating guides prepared which would be used in the event a contingency does occur.</i></p> <p><i>There is no need to plan or build facilities to meet Planning Standard 1.A when Planned Outages can be accommodated within the frame work of existing guidelines and procedures. Studies conducted for the operating horizon are not the subject of this standard.</i></p> <p><i>Therefore, the SAR drafting team directs the standard drafting team to delete the requirement for the prior planned outage from the standard given that known planned outages must be included in studies that are conducted during the operating horizon which are not the subject of this standard but which are required in accordance with NERC Standard 200, "Operate Within Interconnection Reliability Operating Limits Standard" and NERC Standard 600, "Determine Facility Ratings, Operating Limits, and Transfer Capabilities".</i></p>

	<p><i>Note: The above suggested wording is similar to the MAPP/MEC comment for Question 4, and the SAR DT is offering a similar consideration:</i></p> <p><i>Consideration by the SAR DT</i> <i>See the SAR DT's response to MAPP above. We believe the revised wording in the present SAR adequately addresses these concerns.</i></p>
SEMINOLE	<p>Many grid operations difficulties occur when a line is scheduled out for maintenance. If this SAR is going to address required N-2 planning assessments, then it must be clear and specific regarding the conditions when N-2 assessments are appropriate and the specific criteria for N-2 assessments.</p> <p><i>Consideration by the SAR DT</i> <i>See the SAR DT's response to MAPP above. We believe the revised wording in the present SAR adequately addresses these concerns</i></p>

COMMENTS ON APPLICABLE RATINGS

<p>ALLEGHENY</p>	<p>From SAR- Version 2: ".....Performance requirements for Category C events shall be re-evaluated. For example, for certain Category C events, such as #2, #3 and #9 events, consider removing references to "Applicable Ratings" to clarify that the performance requirement is "No Cascading Outages are Allowed".....".</p> <p>This bullet does not appear necessary. "No Cascading Outages" is already part of Table I for these events. Removing "Applicable Ratings" would not add to the clarity.</p> <p>Consideration by the SAR DT</p> <p><i>The wording in the present SAR was revised to remove the referenced language.</i></p> <p><i>The SAR DT is recommending that the Standard DT conduct a review to determine whether the events in existing Table I are classified correctly. In conducting its review of the likelihood of events and acceptable performance requirements, the Standard DT should clarify ambiguities in performance requirements, specifically cascading outages and Applicable Ratings (A/R).</i></p> <p><i>For example, the Standard should clarify tests used for considering cascading, such as divergent power flow, overload limits post contingency, voltage magnitudes, etc. The Standard should also clarify that different ratings may be applicable to different categories of events and perhaps to different types of events with a category (specified by entities in accordance with STD 600).</i></p>
<p>AMEREN</p>	<p>We agree that some of the contingency categories should be reviewed. See AMEREN's comment for Question 1 (c) in this document – approach (1): keep same categories but re-classify certain events as Category D.</p> <p>Consideration by the SAR DT</p> <p><i>See the SAR DT's global consideration of your Question 1(c) comment.</i></p>
<p>BPA</p>	<p>Applicable Ratings: There is a need to tighten up the methodology for Applicable Ratings to ensure that compliance with this standard is measurable. We assume that this will take place in the Determine Facility Ratings Standard although we are concerned about how this is progressing.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending that Applicable Ratings (A/R) be clarified by the Standard DT and the Standard DT will evaluate your comment at that time.</i></p>
<p>IMO, ISONE, NPCC</p>	<p>We are not in favor of removing references to "Applicable Ratings". Despite the fact that the performance requirement would be "No Cascading Outages are Allowed", the "Applicable Ratings" should always be respected.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending that Applicable Ratings (A/R) be clarified by the Standard DT and the Standard DT will evaluate your comment at that time.</i></p>

<p>MAPP</p>	<p>MAPP urges the SAR drafting team to clarify the meaning of the term "Applicable Ratings" and determine if it is possible to have different A/Rs for different categories.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending that Applicable Ratings (A/R) be clarified by the Standard DT and the Standard DT will evaluate your comment at that time.</i></p>
<p>MEC</p>	<p>From SAR- Version 2: ".....Performance requirements for Category C events shall be re-evaluated. For example, for certain Category C events, such as #2, #3 and #9 events, consider removing references to "Applicable Ratings" to clarify that the performance requirement is "No Cascading Outages are Allowed".....".</p> <p>MEC urges the SAR drafting team to add Category C#1, #6, #7 and #8 events to the bullet above, to clarify the performance requirement for certain Category C events.</p> <p>Consideration by the SAR DT</p> <p><i>The wording concerning A/R has been revised in the present SAR.</i></p> <p><i>There was no clear consensus from industry that the events in Categories B, C and D in Table I should be or should not be re-classified. The SAR DT is recommending that the Standard DT conduct a review to evaluate whether the events are classified correctly.</i></p> <p><i>All parties will have an opportunity to participate in the Standard drafting process, including commenting on the draft Standard. Specific concerns should be brought up at that time.</i></p>
<p>MEC</p>	<p>MEC urges the SAR drafting team to direct the Standard Drafting Team to remove references to "Applicable Ratings" from all events listed (see MEC comment above), since information is readily available which demonstrates that the listed events are much less likely than other Category C events.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending that Applicable Ratings (A/R) be clarified by the Standard DT and the Standard DT will evaluate your comment at that time.</i></p>
<p>MEC</p>	<p>MEC urges the SAR drafting team to include the following statement in the SAR:</p> <p>"The Standard should clarify how breaker failure events (Category C2, C6, C7, C8, and C9 events) are to be considered given that operating a breaker with disconnects open or eliminating a breaker are technically acceptable mitigation schemes for such events. Such mitigation schemes actually result in less reliable system designs and system operating configurations. Thus including Applicable Ratings in the Standard for these lower probability breaker failure events can send the wrong reliability signals to NERC members."</p> <p>This statement reflects another reason why breaker failure events should be reclassified such that Applicable Ratings is no longer considered a requirement for these low probability events.</p> <p>Consideration by the SAR DT</p> <p><i>See the SAR DT's consideration of MEC's first comment above.</i></p>

<p>MEC</p>	<p>MEC urges the SAR drafting team to consider NOT reclassifying any of the Category C events to Category D but instead deleting the Applicable Rating requirements from the lower probability Category C events.</p> <p>MEC believes that the performance requirements for lower probability Category C events should be to protect for cascading, instability, and uncontrolled separation. It is MEC's belief that this was the intent of the drafting team that originally developed the existing NERC Planning Standards.</p> <p>Consideration by the SAR DT</p> <p><i>See the SAR DT's consideration of MEC's first comment above.</i></p>
<p>NYSRC</p>	<p>From SAR- Version 2: ".....Performance requirements for Category C events shall be re-evaluated. For example, for certain Category C events, such as #2, #3 and #9 events, consider removing references to "Applicable Ratings" to clarify that the performance requirement is "No Cascading Outages are Allowed".....".</p> <p>The above bullet should be removed. This would be a weakening of the criteria.</p> <p>Consideration by the SAR DT</p> <p><i>There was no clear consensus from industry that the events in Categories B, C and D in Table I should be or should not be re-classified. The SAR DT is recommending that the Standard DT conduct a review to evaluate whether the events are classified correctly.</i></p> <p><i>All parties will have an opportunity to participate in the Standard drafting process, including commenting on the draft Standard. Concerns that changes made may weaken the Standard should be brought up at that time.</i></p>
<p>R. Snow</p>	<p>Clarify that the "applicable ratings" for multiple events should be consistent with supplying firm load and firm transactions until the outages are repaired or switching mitigates the overloads. For example, one applicable rating would be the short time rating of equipment that was stressed when a transformer failed. However, there must be a method of supplying the load pocket for the duration to repair/replace the transformer that does not involve long term rotating blackouts. Just achieving "no cascading outages" is not sufficient.</p> <p>Consideration by the SAR DT</p> <p><i>The SAR DT is recommending that Applicable Ratings (A/R) be clarified by the Standard DT and the Standard DT will evaluate your comment at that time.</i></p>

COMMENT ON SHORT CIRCUIT CURRENT

AMEREN	<p>We assume that short circuit current refers to fault duty or interrupting current.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>Fault duty and interrupting current refer to the ratings of transmission facilities. The short circuit current is compared to these ratings.</i></p>
--------	---

COMMENTS ON OTHER AREAS THAT SHOULD BE ADDED OR CLARIFIED

AESO	<p>There should be a clear distinction between the appropriate use and application of RAS (or SPS) and "safety nets".</p> <p>Consideration by the SAR DT <i>Based on industry comments on the first posting (V1) of the SAR, there was a strong preference not to specify <u>how</u> to achieve reliability performance requirements. Therefore, the SAR does not specifically address these issues/distinctions.</i></p>
AMEREN	<p>The "projected level of transfers" defined in the Standard – what does this include? Should it include/consider all transmission reservations including roll-over-rights?</p> <p>Consideration by the SAR DT <i>The present SAR has been revised to specify that system models must be developed and shared, including documenting the methodology for incorporating planned generation assets (including transfers) in the model. The projected levels of transfers are determined by each Transmission Planner, and these may include rollover provisions as appropriate.</i></p> <p><i>Note: See KCPL & MAPP comments under the "System Models" table in this document, and the SAR DT's consideration of those comments.</i></p>
MAPP	<p>MAPP asks that the SAR drafting team add a bullet to the SAR that requires that the Standard drafting team consider the development of reactive power margin and transfer power margin standards which expand beyond existing NERC Standard I.D.</p> <p>Consideration by the SAR DT <i>The NERC Planning Committee is reviewing Regional reactive power and voltage control practices. Their findings may need to be incorporated into the new Planning Standard (STD 500) when this review is completed. Standard 600 addresses system operating limits and transfer capability. Whereas this SAR DT did not attempt to duplicate these efforts, the present SAR does not preclude the Standard Drafting Team from further refining reactive power margins and/or power transfer margins.</i></p> <p><i>In the present SAR, a bullet has been added that the Standard address requirements on reactive planning, with specific reference to steady state and transient voltage stability criteria.</i></p>
MAPP	<p>MAPP notes that Standard 600, "Determine Facility Ratings, Operating Limits, and Transfer Capabilities" has been drafted to do away with the references to Categories A through D. The criteria are just listed in the standard. MAPP asks that the SAR drafting team require that the standard drafting team for Standard 500 also eliminate the category references to be consistent with the Standard 600 approach.</p> <p>Consideration by the SAR DT <i>This SAR 500 DT does not believe that Standard 500 necessarily has to have</i></p>

	<p><i>the same format as Standard 600. However, we have revised the present Standard 500 SAR to provide for coordination between the two Standards.</i></p>
<p>MAPP & MEC</p>	<p>In general, MAPP and MEC support the six bullets that the SAR drafting team has provided on page SAR-5 (of SAR-Version 2) with the amendments and additions described above in our comments. These bullets add needed details to the SAR.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The present SAR has been revised to reflect appropriate details.</i></p>
<p>R. Snow</p>	<p>New section: The subject of assuring that generation is deliverable to the load should be added. This should not be vague but should be defined by a specific set of tests and the expected range of results. In doing these tests, reliance on capacity assigned to other regions should be limited to amounts identified and accepted by adjacent regions. For example, if a region is assuming it will have net purchases from adjacent regions, the other regions must show a net sale.</p> <p><i>Consideration by the SAR DT</i></p> <p><i>The NERC Planning Committee is tackling this deliverability issue, as identified by the Resource and Transmission Adequacy Task Force (RTATF). This new Transmission Planning Standard (STD 500) may need to be revised in the future to reflect integration with Resource Adequacy Standards.</i></p>

INDUSTRY COMMENTER KEY

TOTAL ENTITIES COMMENTING; 28

TOTAL INDIVIDUALS COMMENTING 121

AEP: AEP Service Corp, Raj Rana

Standard Authorization Request Form

Title of Proposed Standard	Assess Transmission Future Needs and Develop Transmission Plans
Request Date	May 01, 2004

SAR Requestor Information	SAR Type (Put an 'x' in front of one of these selections)	
Name Paul Rocha	<input checked="" type="checkbox"/>	New Standard
Primary Contact Paul Rocha	<input type="checkbox"/>	Revision to existing Standard
Telephone (713) 207-2768 Fax	<input type="checkbox"/>	Withdrawal of existing Standard
E-mail paul.rocha@centerpointenergy.com	<input type="checkbox"/>	Urgent Action

Purpose/Industry Need (Provide one or two sentences)

To establish a standard for assessing and planning the transmission systems in North America. The transmission system must be assessed and planned to ensure that it performs its intended functions in providing reliable delivery of power for the future needs of customers.

Reliability Functions

The Standard will Apply to the Following Functions (Check box for each one that applies by double clicking the grey boxes.)		
<input checked="" type="checkbox"/>	Reliability Authority	Ensures the reliability of the bulk transmission system within its Reliability Authority area. This is the highest reliability authority.
<input type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within its metered boundary and supports system frequency in real time
<input type="checkbox"/>	Interchange Authority	Authorizes valid and balanced Interchange Schedules
<input checked="" type="checkbox"/>	Planning Authority	Plans the bulk electric system
<input type="checkbox"/>	Resource Planner	Develops a long-term (>1year) plan for the resource adequacy of specific loads within a Planning Authority area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a long-term (>1 year) plan for the reliability of transmission systems within its portion of the Planning Authority area.
<input type="checkbox"/>	Transmission Service Provider	Provides transmission services to qualified market participants under applicable transmission service agreements
<input checked="" type="checkbox"/>	Transmission Owner	Owns transmission facilities
<input type="checkbox"/>	Transmission Operator	Operates and maintains the transmission facilities, and executes switching orders
<input type="checkbox"/>	Distribution Provider	Provides and operates the “wires” between the transmission system and the customer
<input type="checkbox"/>	Generator Owner	Owns and maintains generation unit(s)
<input type="checkbox"/>	Generator Operator	Operates generation unit(s) and performs the functions of supplying energy and Interconnected Operations Services
<input type="checkbox"/>	Purchasing-Selling Entity	The function of purchasing or selling energy, capacity and all necessary Interconnected Operations Services as required
<input type="checkbox"/>	Market Operator	Integrates energy, capacity, balancing, and transmission resources to achieve an economic, reliability-constrained dispatch.
<input checked="" type="checkbox"/>	Load-Serving Entity	Secures energy and transmission (and related generation services) to serve the end user

Reliability and Market Interface Principles

Applicable Reliability Principles (Check boxes for all that apply by double clicking the grey boxes.)	
<input checked="" type="checkbox"/>	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input type="checkbox"/>	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
<input type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
<input type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified and have the responsibility and authority to implement actions.
<input type="checkbox"/>	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
Does the proposed Standard comply with all of the following Market Interface Principles? (Select 'yes' or 'no' from the drop-down box by double clicking the grey area.)	
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes	
2. An Organization Standard shall not give any market participant an unfair competitive advantage. Yes	
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes	
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes	
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes	

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.)

The Standard shall establish requirements for assessing the performance of planned bulk electric transmission systems and the requirements for documenting plans to remedy any inadequacies identified in the process of conducting such assessments.

The scope of such assessments and plans is for a future planning period (planning horizon) starting at one year and extending to five years or more.

The planning horizon must be long enough to permit timely implementation of viable solutions to remedy the potential inadequacies found. Planning horizons beyond 5 years may be needed to meet regulatory or legislative requirements, or may be based on the judgment of the Transmission Planner or Planning Authority.

The scope *does not* include the operating horizon less than one year. While the planning horizon is intended to provide sufficient time for facility additions, there is no intent to exclude appropriate operating procedures as options to correct potential transmission inadequacies. Such procedures should also be included in the Transmission Plan.

The Standard will consider the transition from the operating horizon to the planning horizon. In particular, the Standard will assure consistency between reliability requirements set forth in the Standards for Planning (for example, this Standard 500, "Assess Transmission Future Needs and Develop Transmission Plans") and similar criteria required by other Standards (such as Standard 600, "Determine Facility Ratings, Operating Limits and Transfer Capabilities"), which also apply in operations.

In addition, the Standard shall explain the relationship between the reliability requirements for operations and those for planning, so that differences are better understood.

The Standard shall identify reliability performance requirements, but shall not specify *how* to achieve such performance requirements.

The applicable portions of the following existing NERC Planning Standards will be used as the starting point in drafting these requirements:

- I.A Transmission Systems
- I.B Reliability Assessment
- I.D Voltage Support & Reactive Power
- II.A System Data
- II.D Actual and Forecast Demands

The Standard shall require that system models be developed, maintained and shared in a manner consistent with the Functional Model and appropriate information-sharing policies. Included will be requirements that each Planning Authority and Transmission Planner document modeling assumptions, including the methodology used for incorporating planned generation assets (including transfers) in the model, as well as how such generation is dispatched. The Standard shall consider a requirement for Load Serving Entities (LSEs) to provide forecast resource data for input to the models.

While methodologies and assumptions must be documented, the Standard will *not* prescribe specific tools to be used in the performance assessment of the planned systems.

The Standard will identify the various planning functions that are responsible for compliance with the standard criteria. The assignment of compliance responsibility will be consistent with the Functional Model.

This Standard will *not* include requirements for:

- Resource Planning (i.e., assessing or ensuring the availability of adequate aggregate generation resources to serve aggregate load).
- Planning generation additions to remedy any aggregate generation resource inadequacies.
- Developing Transmission Plans to mitigate congestion due to economy transfers of generation resources.

However, the Standard should neither preclude nor require the consideration of generation or load (demand side management) as alternatives to transmission reinforcement/reconfiguration when developing solutions to potential transmission inadequacies.

While the Standard should start from and closely align with the existing Planning Standards I.A, I.B, I.D, II.A, and II.D, the system conditions to be studied or assessed may need to be better defined or clarified.

Examples of areas that should be considered for clarification in the Standard include:

- The Standard should clarify that the requirement to assess the performance at *all* demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with regionally-defined criteria.
- The Standard should provide a clearer definition of “cascading outages”, including what constitutes a cascading state. The Standard should also consider providing a clearer definition of “system stable”. These definitions must be coordinated and consistent with definitions in other new Standards being drafted by NERC, such as Standards 200 and 600.
- The Standard should take into account the variability of generation, including unit maintenance outages, weather and time of day. Variability of load due to factors such as weather and time of day should also be considered.
- The Standard should continue to use deterministic criteria. The criteria embodied in Table 1 of existing Planning Standard I.A shall be used as a starting point. Following a review of the likelihood, duration, impact of events, and definition of applicable ratings (A/R) in existing Table I, a re-classification of Table I events should be considered, as necessary, for inclusion in the new Standard.

Other changes should be considered for incorporation into the new Standard. Such changes could include:

- (1) Addition or deletion of categories/events/performance requirements.
- (2) Use of probabilistic planning methods.
- (3) Re-definition of categories (e.g., categories determined by event probability levels or ranges).
- (4) Differences in requirements for an event based on a range of event probabilities (for example, recognize that longer lines have a greater probability of outage than shorter lines).

(5) An alternative table, similar to Table I of existing Planning Standard I.A, except allowing for probabilistic planning criteria.

(6) Provision for a specific facility with an abnormal outage probability to have different performance requirements.

The list above is intended to be illustrative and not exhaustive or mutually exclusive. As allowed by the Standards Development Process, Regions may submit Regional Differences.

- Existing Planning Standard S1, S2, S3, S4 and Table I, Categories A, B, C, and D should be clarified on the issue of how a planned outage should be used in an assessment.

The Standard should specify whether the planned outage requirement should be retained for Categories B and C. If retained, the requirement should be clarified in such a way that it can be practically implemented. In particular, the Transmission Planner should not be required to exhaustively test its system for every conceivable planned outage (including maintenance outages) in addition to every conceivable Category B and C contingency. The Standard should clarify that the planned outage requirement does not apply to Categories A and D.

- The Standard should address and rectify ambiguities in performance requirements, specifically cascading outages and applicable ratings (A/R). This applies to all Categories, especially Category C.

For example, the Standard should clarify tests used for considering cascading, such as divergent power flow, post-contingency overload limits, voltage magnitudes, etc. The Standard should also clarify that different ratings may be applicable to different categories of events and perhaps different types of events within a category (specified by entities in accordance with Standard 600).

- The Standard should include requirements to ensure that the maximum available short circuit current does not exceed facility owner specifications.
- The Standard should also address requirements on reactive planning with specific reference to steady state and transient voltage stability criteria.
- The Standard should address requirements for reporting (perhaps to the Regions) on the progress or status of implementing the plans developed in accordance with the Standard. However, any such reporting requirements should be consistent with the Resource & Transmission Adequacy Task Force Recommendation #2, and should not impose undue burdens upon transmission entities

Related Standards

Standard No.	Explanation

Related SARs

SAR ID	Explanation
FACILITY_RATINGS_01_01	<i>“Determine Facility Ratings, Operating Limits and Transfer Capabilities”</i> . The Planning Standard will use some data collected within the “Facility Ratings” SAR. The Draft “Facility Ratings” Standard, Section 603, establishes some guidelines for the planning function to set operating limits based on Table 1 of the existing Planning Standard I.A.
OPER_WITHN_LMTS_01_01	<i>“Operate Within Interconnection Reliability Operating Limits”</i> . This Planning Standard needs to establish future planning criteria such that the bulk electric power system can be operated within operating limits.

Planning Std. I.A	Transmission Systems: Plan within ratings, avoid cascading outages, uncontrolled system separation, and voltage and transient instability.
Planning Std. I.B	Reliability Assessment
Planning Std. I.D	Voltage Support & Reactive Power
Planning Std. II.A	System Data
Planning Std. II.D	Actual & Forecast Demands

MAPP & MEC believe the following information supports our proposed new reclassification by demonstrating that the events that MAPP & MEC recommend for reclassification are the low probability Category C events. MAPP & MEC recognize that published outage data are subject to interpretation, potential inaccuracy, and change through time; however, we believe that MAPP & MEC operating experience with transmission element outages supports the statistical summary provided in the following table.

BPA Data

Category	Contingencies	Outages per year	Source of Data
B1	Generator	4	NW Federal system is mostly hydro generation in remote locations and these outages are usually of little consequence to the power system. These outage data are based on three thermal plants located in load areas. Due to the small size of this sample, they may not be very useful. These outages average 109 hour duration.
B2	Transmission Circuit	0.97	BPA data for 225 lines 200-kV through 550-kV, 1985-2003 data (19 years), average length 50.5 miles, outages with duration greater than 1 minute only. Five hour average duration.
B3	Transformer	0.037	IEEE Paper 91 SM 442-4 PWRS, BPA autotransformers, winding voltages 115 to 550-kV. 28 day average duration.
B4	Single Pole DC Line	9	BPA data for PDCI, 845 miles (one line only). 8.99 outages per year with total annual outage time of 170 hours. Not including terminal outages. 19 hour average duration.
C1	Bus section	0.00733	BPA data for 115 stations with voltages between 230-kv through 500-kV, 17.8 years of data, resulting in 15 events.
C2	Breaker internal fault	0.00079	1994 CIGRE Brochure 83: data for 230 and 500-kV breakers: insulation breakdown.
C2	Breaker fails to open	0.00569	1994 CIGRE Brochure 83: data for 230 and 500-kV breakers: failure to open.
C3	Two Line Dependent	0.08700	BPA data for sustained multiple outages (greater than one minute) for its 500-kV lines, 1985-2003 data (19 years). Calculated for two lines with 50 mile common corridor length.
C3	Two Line Independent	0.00110	Calculated based on single contingency rate indicated above: 1 outage per year with duration of 5 hours
C3	Generator and Transformer	0.01400	Calculated based on single contingency outage rates indicated above: 0.037 outages per year of duration 28 days for transformers and 4 outages per year of duration 109 hours for generators.
C3	Line and Transformer	0.00290	Calculated based on single contingency outage rates indicated above: 1 outage per year of duration 5 hours for line and .037 outages per year of duration 28 days for transformer.
C3	Two Generator	0.45000	Calculated based on single contingency outage rate indicated above: 4 outages per year with duration 109 hours each. Small sample of data - may not be representative.

C3	Line and Generator	0.05500	Calculated based on single contingency outage rates indicated above: 1 outage per year of duration 5 hours for line and 4 outages per year of duration 109 hours for generator.
C4	Bipolar DC Line	0.35000	Calculated based on single contingency outage rate indicated above: 9 outages per year for duration of 19 hours
C5	2 circuits on multiple towerline	0.05100	BPA data for sustained multiple outages (greater than one minute) for its 500-kV double circuit lines, 1985-2003 data (19 years). Calculated for double circuit line with 50 mile length.
C6, C7, C8, C9	Protection failure	0.11969	BPA Data for 115 stations with voltages 230 through 500-kV, 17.8 years of data, resulted in 245 events of pretection failure.
C6	SLG Fault Generator with protection failure	0.47875	Generator single contingency outage rate from above multiplied by protection failure rate (0.11969)
C7	SLG Fault Transmission circuit with protection failure	0.11490	Transmission line single contingency outage rate from above multiplied by protection failure rate (0.11969)
C8	SLG Fault Transformer with protection failure	0.00443	Transformer single contingency outage rate from above multiplied by protection failure rate (0.11969)
C9	Bus section fault with protection failure	0.00088	Bus fault outage rate from above multiplied by protection failure rate (0.11969)

Data provided by Marv Landauer based on outage data collected by BPA.

Assess Transmission Planning Future Needs and Develop Transmission Plans- Standard Drafting Team Nomination Form

Please return this form to sarcomm@nerc.com by November 18, 2005. For questions, please contact Mark Ladrow at 609-452-8060 or mark.ladrow@nerc.net.

Please note this Standard drafting team will likely meet initially in mid-December, 2005 to review comments posted on the SAR and to begin drafting the proposed standards. The SAC has directed the drafting team to consider the reduced scope necessitated by the adoption of the current reliability standards and to specifically delineate this reduction in scope during its first public posting. The team will meet as necessary to finalize the scope of standard development activity and to draft the standard(s). The meeting schedule has not been determined yet. It is expected the teams will meet several times in 2006. **All candidates should be prepared to participate actively at these meetings.**

Proposed Standard: Assess Transmission Future Needs and Develop Transmission Plans. The SAR is provided at: [SAR LINK](#)

Name:

Organization:

Address:

Office Telephone:

Mobile Telephone:

Fax:

Email:

Please briefly describe your experience and qualifications to serve on the Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team. Candidates should have expertise in one or more of the following areas: transmission operations; transmission planning; or regulatory or legal experience related to any of the listed areas. Previous experience working on or applying NERC standards is beneficial, but not a requirement.

Standard Authorization Request Form

Title of Proposed Standard	Assess Transmission Future Needs and Develop Transmission Plans
Request Date	May 01, 2004
Revised: April 30, 2006	

SAR Requestor Information	SAR Type (Put an 'x' in front of one of these selections)
Name Paul Rocha	<input checked="" type="checkbox"/> New Standard
Primary Contact Paul Rocha	<input type="checkbox"/> Revision to existing Standard
Telephone (713) 207-2768 Fax	<input type="checkbox"/> Withdrawal of existing Standard
E-mail paul.rocha@centerpointenergy.com	<input type="checkbox"/> Urgent Action

Purpose/Industry Need (Provide one or two sentences)

To establish a standard for assessing and planning the transmission systems in North America. The transmission system must be assessed and planned to ensure that it performs its intended functions in providing reliable delivery of power for the future needs of customers.

Reliability Functions

The Standard will Apply to the Following Functions (Check box for each one that applies by double clicking the grey boxes.)		
<input checked="" type="checkbox"/>	Reliability Authority	Ensures the reliability of the bulk transmission system within its Reliability Authority area. This is the highest reliability authority.
<input type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within its metered boundary and supports system frequency in real time
<input type="checkbox"/>	Interchange Authority	Authorizes valid and balanced Interchange Schedules
<input checked="" type="checkbox"/>	Planning Authority	Plans the bulk electric system
<input type="checkbox"/>	Resource Planner	Develops a long-term (>1year) plan for the resource adequacy of specific loads within a Planning Authority area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a long-term (>1 year) plan for the reliability of transmission systems within its portion of the Planning Authority area.
<input type="checkbox"/>	Transmission Service Provider	Provides transmission services to qualified market participants under applicable transmission service agreements
<input checked="" type="checkbox"/>	Transmission Owner	Owns transmission facilities
<input type="checkbox"/>	Transmission Operator	Operates and maintains the transmission facilities, and executes switching orders
<input type="checkbox"/>	Distribution Provider	Provides and operates the “wires” between the transmission system and the customer
<input type="checkbox"/>	Generator Owner	Owns and maintains generation unit(s)
<input type="checkbox"/>	Generator Operator	Operates generation unit(s) and performs the functions of supplying energy and Interconnected Operations Services
<input type="checkbox"/>	Purchasing-Selling Entity	The function of purchasing or selling energy, capacity and all necessary Interconnected Operations Services as required
<input type="checkbox"/>	Market Operator	Integrates energy, capacity, balancing, and transmission resources to achieve an economic, reliability-constrained dispatch.
<input checked="" type="checkbox"/>	Load-Serving Entity	Secures energy and transmission (and related generation services) to serve the end user

Reliability and Market Interface Principles

Applicable Reliability Principles (Check boxes for all that apply by double clicking the grey boxes.)	
<input checked="" type="checkbox"/>	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input type="checkbox"/>	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
<input type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
<input type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified and have the responsibility and authority to implement actions.
<input type="checkbox"/>	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
Does the proposed Standard comply with all of the following Market Interface Principles? (Select 'yes' or 'no' from the drop-down box by double clicking the grey area.)	
1.	The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2.	An Organization Standard shall not give any market participant an unfair competitive advantage. Yes
3.	An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4.	An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5.	An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.)

The Standard shall establish requirements, where requirements don't exist, and verify and clarify the existing reliability standards for assessing the performance of planned bulk electric transmission systems and the requirements for documenting plans to remedy any inadequacies identified in the process of conducting such assessments.

The scope of such assessments and plans is for a future planning period (planning horizon) starting beyond the operating horizon and extending to five years or more.

The planning horizon must be long enough to permit timely implementation of viable solutions to remedy the potential inadequacies found. Planning horizons beyond 5 years may be needed to meet regulatory or legislative requirements, or may be based on the judgment of the Transmission Planner or Planning Authority.

The scope *does not* include the operating horizon, typically less than one year. While the planning horizon is intended to provide sufficient time for facility additions, there is no intent to exclude appropriate operating procedures as options to correct potential transmission inadequacies. Such procedures should also be included in the Transmission Plan.

The Standard will address the transition from the operating horizon to the planning horizon. In particular, the Standard will assure consistency between reliability requirements set forth in the Standards for Planning (for example, TPL-001 through TPL-004) and similar criteria required by other Standards (such as FAC-008-1 through FAC-013-1 standards, "Determine Facility Ratings, Operating Limits and Transfer Capabilities"), which also apply in operations.

In addition, the Standard shall address the relationship between the reliability requirements for operations and those for planning, so that differences are better understood.

The Standard shall identify reliability performance requirements, but shall not specify *how* to achieve such performance requirements.

The existing NERC Reliability Standards TPL-001-0 through TPL-004-0 will be used as the starting point in drafting these requirements. Included will be requirements that each Planning Authority and Transmission Planner document modeling assumptions, including the methodology used for incorporating planned generation assets (including transfers) in the model, as well as how such generation is dispatched. The Standard may address a requirement for Load Serving Entities (LSEs) to provide forecast resource data for input to the models.

While methodologies and assumptions must be documented, the Standard will *not* prescribe specific tools to be used in the performance assessment of the planned systems.

This Standard will *not* include requirements for:

- Resource Planning (i.e., assessing or ensuring the availability of adequate aggregate generation resources to serve aggregate load).
- Planning generation additions to remedy any aggregate generation resource inadequacies.
- Developing Transmission Plans to mitigate congestion due to economy transfers of generation resources.

However, the Standard should neither preclude nor require the consideration of generation or load (demand side management) as alternatives to transmission reinforcement/reconfiguration when developing solutions to potential transmission inadequacies.

While the Standard should start from and closely align with the existing Reliability Standards TPL-001-0 through TPL-004-0, the system conditions to be studied or assessed may need to be better defined or clarified.

Examples of areas that should be considered for clarification in the Standard include:

- The Standard should clarify that the requirement to assess the performance at *all* demand levels does not mean that a multitude of transmission models need to be created for every possible demand level, only that a representative sample covering critical operating conditions needs to be modeled in accordance with appropriate criteria. (TPL-001-0 through TPL-004-0)
- The Standard should provide a clearer definition of “cascading outages”, including what constitutes a cascading state. The Standard should also consider providing a clearer definition of “system stable”. (TPL-001-0 through TPL-004-0)

These definitions must be coordinated and consistent with definitions in other new Standards either being drafted or recently approved by NERC, such as Standards FAC-008-1 through FAC-013-1 (Determine Facility Ratings) and IRO-007-1 through IRO-013-1 (Operate within Interconnection Reliability Operating Limits) .

- The Standard should take into account the variability of generation, including unit maintenance outages, weather and time of day. Variability of load due to factors such as weather and time of day should also be considered. (TPL-001-0 through TPL-004-0)
- The Standard should continue to use deterministic criteria. The criteria embodied in Table 1 of existing Reliability Standards TPL-001-0 through TPL-004-0 shall be used as a starting point. Following a review of the likelihood, duration, impact of events, and definition of applicable ratings in existing Table I, a reclassification of Table I events should be considered, as necessary, for inclusion in the new Standard.

Other changes should be considered for incorporation into the new Standard. Such changes could include:

- 1) Addition or deletion of categories/events/performance requirements.
- 2) Use of probabilistic planning methods.
- 3) Re-definition of categories (e.g., categories determined by event probability levels or ranges).
- 4) Differences in requirements for an event based on a range of event probabilities (for example, recognize that longer lines have a greater probability of outage than shorter lines).
- 5) An alternative table, similar to Table I of existing Reliability Standards TPL-001-0 through TPL-004-0, except allowing for probabilistic planning criteria.
- 6) Provision for a specific facility with an abnormal outage probability to have different performance requirements.

The list above is intended to be illustrative and not exhaustive or mutually exclusive. As allowed by the Standards Development Process, Regions may submit Regional Differences.

- Existing Reliability Standard TPL-001-0 through TPL-004-0 and Table I, Categories A, B, C, and D should be clarified on the issue of how a planned outage should be used in an assessment. The Standard should specify whether the planned outage requirement should be retained for Categories B and C. If retained, the requirement should be clarified in such a way that it can be practically implemented. In particular, the Transmission Planner should not be required to exhaustively test its system for every conceivable planned outage (including maintenance outages) in addition to every conceivable Category B and C contingency. The Standard should clarify that the planned outage requirement does not apply to Categories A and D.
- The Standard should address and rectify ambiguities in performance requirements, specifically cascading outages and applicable ratings. This applies to all Categories, especially Category C. For example, the Standard should clarify tests used for considering cascading, such as divergent power flow, post-contingency overload limits, voltage magnitudes, etc. The Standard should also clarify that different ratings may be applicable to different categories of events and perhaps different types of events within a category (specified by entities in accordance with (IRO-007-1 through IRO-013-1 (Operate within Interconnection Reliability Operating Limits))).

- The Standard should include requirements to ensure that the maximum available short circuit current does not exceed facility owner specifications.
- The Standard should also address requirements on reactive planning with specific reference to steady state and transient voltage stability criteria.
- The Standard should address requirements for reporting (perhaps to the Regions) on the progress or status of implementing the plans developed in accordance with the Standard. However, any such reporting requirements should be consistent with the Resource & Transmission Adequacy Task Force Recommendation #2, and should not impose undue burdens upon transmission entities.

Related Standards

Standard No.	Explanation

Related SARs

SAR ID	Explanation
FACILITY_RATINGS_01_01	<i>“Determine Facility Ratings, Operating Limits and Transfer Capabilities”</i> . The Planning Standard will use some data collected within the “Facility Ratings” SAR. The Draft “Facility Ratings” Standard, Section 603, establishes some guidelines for the planning function to set operating limits based on Table 1 of the existing Planning Standard I.A.
OPER_WITHN_LMTS_01_01	<i>“Operate Within Interconnection Reliability Operating Limits”</i> . This Planning Standard needs to establish future planning criteria such that the bulk electric power system can be operated within operating limits.

MAPP & MEC believe the following information supports our proposed new reclassification by demonstrating that the events that MAPP & MEC recommend for reclassification are the low probability Category C events. MAPP & MEC recognize that published outage data are subject to interpretation, potential inaccuracy, and change through time; however, we believe that MAPP & MEC operating experience with transmission element outages supports the statistical summary provided in the following table.

Standards Authorization Request Form

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

This SAR is intended to supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans dated April 30, 2006 in support of Standards Project 2006-02.

The revisions to the following standards would improve technical clarity and address concerns identified by stakeholders and FERC:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Revisions to TPL-001 through TPL-004 are already underway (Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team) with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments. The expansion of the work already underway with TPL-001 through TPL-004 will focus on the general improvements to the standard identified through the attached *Appendix A: Reliability Standard Review Guidelines* and the FERC and stakeholder concerns identified in the attached *Appendix B: TPL-001 through TPL-006 Technical Issues List*.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The purpose of modifying this set of standards is to:

1. Provide an adequate level of reliability for the North American bulk power systems — ensure each of the standards is complete and the requirements are set at an appropriate level to ensure reliability.
2. Ensure each of the standards is enforceable as a mandatory reliability standard with financial penalties — the applicability to bulk power system owners, operators, and users, and as appropriate particular classes of facilities, is clearly defined; the purpose, requirements, and measures are results-focused and unambiguous; the consequences of violating the requirements are clear.
3. Make general improvements using the Reliability Standard Review Guidelines and consider the items mentioned in the Technical Issues Lists prepared by the NERC staff which attempt to capture comments from the:
 - FERC NOPR (Docket #RM06-16-00 dated October 20, 2006) ,
 - FERC staff report dated May 11, 2006 concerning NERC standards submitted with ERO application,
 - Version 0 and Phase 3&4 standards development (see note 1),
 - Violations Risk Factors (VRF) drafting team (see note 1),
 - Regional Fill-in-the-Blank Team (RRSWG — a NERC working group involved

Standards Authorization Request Form

with regional standards development), and

- Draft SAR for Planning Authority

The SDT should also consider any other issues that were not completely captured but were stated or referenced in the above materials.

Note 1: Comments received from the industry during public postings of the TPL subject matter were sometimes outside the work being posted or outside the drafting team's scope and were not reflected in the drafting of the final work product. These should now be considered by this SDT.

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

The six standards in this set are all Version 0 standards. As the ERO begins enforcing compliance with reliability standards under Section 215 of the Federal Power Act in the United States and applicable statutes and regulations in Canada, the industry needs a set of clear, measurable, and enforceable reliability standards. The Version 0 standards, while a good foundation, were translated from historical operating and planning policies and guides that were appropriate in an era of voluntary compliance. The Version 0 standards and recent updates were put in place as a temporary starting point to start-up the ERO and begin enforcement of mandatory standards. However, it is important to update the standards in a timely manner, incorporating improvements to make the standards more suitable for enforcement and to capture prior recommendations that were deferred during the Version 0 translation and any subsequent standards development that have implications to the TPL standards.

Brief Description: (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

The proposed work effort will address three main issues:

1. Conformance to the new rules and regulations brought about by Section 215 of the Federal Power Act and the creation of the ERO,
2. Supplement the approved work of the existing ATFNSDT to include the necessary revisions to TPL-005 & TPL-006, and
3. Address technical issues raised by FERC and industry stakeholders.

Standards Authorization Request Form

Reliability Functions

The Standard will Apply to the Following Functions <i>(Check box for each one that applies.)</i>		
<input checked="" type="checkbox"/>	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
<input type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
<input type="checkbox"/>	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
<input checked="" type="checkbox"/>	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
<input checked="" type="checkbox"/>	Resource Planner	Develops a (>one year) plan for the resource adequacy of its specific loads within its portion of a Planning Coordinator area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
<input type="checkbox"/>	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
<input checked="" type="checkbox"/>	Transmission Owner	Owns and maintains transmission facilities.
<input type="checkbox"/>	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
<input type="checkbox"/>	Distribution Provider	Delivers electrical energy to the End-use customer.
<input checked="" type="checkbox"/>	Generator Owner	Owns and maintains generating facilities.
<input type="checkbox"/>	Generator Operator	Operates generation unit(s) to provide real and reactive power.
<input type="checkbox"/>	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
<input type="checkbox"/>	Market Operator	Interface point for reliability functions with commercial functions.
<input checked="" type="checkbox"/>	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Standards Authorization Request Form

Reliability and Market Interface Principles

Applicable Reliability Principles <i>(Check box for all that apply.)</i>	
<input checked="" type="checkbox"/>	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input type="checkbox"/>	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
<input type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
<input type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
<input checked="" type="checkbox"/>	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
Does the proposed Standard comply with all of the following Market Interface Principles? <i>(Select 'yes' or 'no' from the drop-down box.)</i>	
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes	
2. An Organization Standard shall not give any market participant an unfair competitive advantage. Yes	
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes	
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes	
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes	

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft a standard based on this description.)

This SAR expands on the work already underway with the Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team, by requiring that TPL-001 through TPL-006 be upgraded in accordance with the Reliability Standards Development Plan 2007–2009. These revisions include the following:

This SAR will be appended to the already approved SAR for Assess Transmission Future Needs and Develop Transmission Plans and will include modifications to all of the following standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

The revisions would improve technical clarity and address concerns identified by stakeholders and FERC. The drafting team will focus on the general improvements to the standards and use as a starting point for the expanded work the subject matter identified in *Appendix A: Reliability Standard Review Guidelines* and the FERC and stakeholder concerns identified in *Appendix B: TPL-001 through TPL-006 Technical Issues List*.

The expanded scope also will include elimination of the ‘fill-in-the-blank’ elements of TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004. The standards need to be modified or retired to address the “fill-in-the blank” components. If the ‘fill-in-the-blank’ requirements are addressed through the contractual arrangements each Region has with the ERO, TPL-005 and TPL-006 could be retired.

The drafting team must ensure that there is consistency in the requirements across the set of TPL standards

The overall development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards, using the attached, Reliability Standard Review Guidelines. In addition, the drafting team will need to make conforming changes to standards impacted by changes made to these six standards.

Appendix A: Reliability Standard Review Guidelines

Applicability

Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose

Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements

Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability

Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations

Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness

Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

Reliability Standard Review Guidelines

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements

In general, requirements for entities to have ‘capabilities’ (this would include facilities for communication, agreements with other entities, etc.), should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to ‘maintain’ their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a ‘unique’ definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the ‘verb list’ from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

This is a requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

Or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replaces the existing 'levels of non-compliance.')

The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — the responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions** — the responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.

Reliability Standard Review Guidelines

- **High: marginal performance or results** — the responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results** — the responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Appendix B: TPL-001 through TPL-006 Technical Issues List

Excerpted from NERC Reliability Standards Development Plan: 2007 - 2009

TPL-001

FERC NOPR

- Require that critical system conditions be determined by conducting sensitivity studies; (*Not necessarily "cook book" but what are the processes someone reasonably skilled in the art would follow.*)
- Require that system conditions and contingencies assessed be reviewed by neighboring systems; (*Looking for coordination with neighboring systems*)
- Modify Requirement R1.3 to substitute the reference to regional reliability organization with Regional Entity;
- Require consideration of planned outages of critical equipment; and
- Modify footnote (a): footnote (a) to Table 1 requires clarification. The NERC Transmission Issues Subcommittee (TIS) 325 recommended that footnote (a) be modified to state explicitly that emergency ratings apply to Category B and C (contingency conditions) and not to Category A (system intact). The Commission proposes that footnote (a) be modified in the revised Reliability Standard as recommended by TIS and that the normal facility rating be in accordance with Reliability Standard FAC-008-1 and normal voltages be in accordance with Reliability Standard VAR-001-1.

FERC Staff Report

- Only for normal
- Doesn't consider planned outages
- Clarify footnote 'a' & 'b' in table
- Stress system during simulations
- Include sensitivity studies
- Include extreme events

Version 0 Industry Comments

- Several semantic issues
- Clarify timing for submittal of corrective plan
- Clarify use of applicable ratings in Table 1, note 'a'
- Need to address deliverability to load
- Define critical system conditions
- Allow for engineering judgment in setting conditions for power flow
- Do planned facilities include just those under construction?
- Need to include multiple time frames
- What is a major load center?
- Table 1 – C.5 goes beyond double circuit outage criteria
- Table 1, items 6, 7, 8 & 9 need footnote stating that they do not apply to generator breaker failure
- Table 1, note 'b' – clarify when to curtail firm deliveries

TPL-001 through TPL-006 Technical Issues List

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

Violation Risk Factors (VRF) Drafting Team Comment

- R1 – time horizon should be long-term planning

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-002:

FERC NOPR

- Require that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- Require the inclusion of the reliability impact of the entities' existing spare equipment strategy; (*Only looking for consideration of spare equipment that has a long lead time such as a transformer*)
- Explicitly require all generators to ride through the same set of Category B and C contingencies as required for wind generators in Order No. 661; (*Document explicit definition of ride through capability for generators*)
- Require documentation of load models used in system studies and supporting rationale for their use;
- Clarify the phrase "permit operating steps necessary to maintain system control;" and
- Clarify footnote (b): modify footnote (b) to state that load shedding for a single contingency is not permitted except in very special circumstances where such interruption is limited to the firm load associated with the failure (consequential load loss).³³⁰ For purposes of clarity, the Commission proposes to require that the phrase "to prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power transfers" be deleted from footnote (b). This statement is more appropriate for Category C events and is already captured by footnote (c) to Table 1, which is applicable to Category C events.

FERC staff report

- Only includes loss of single element
- NERC TIS Report recommendations not addressed

Version 0 Industry Comments

- Define critical system conditions
- Clarify timing for corrective plan
- Address deliverability of generation to load
- Clarify applicable ratings in Table 1, note 'a'
- Don't include generation runback or re-dispatch
- Must study all contingencies and multiple demand levels & time frames
- Don't include planning outage
- Single terminals are not included

Phase III/IV comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

VRF comments

- Time horizon should be long-term planning and R2.2 – redundant with R1.3.8

Comment from draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-003:

FERC NOPR

- Require that critical system conditions be determined by conducting sensitivity studies (as elaborated in our discussion of TPL-001-0);
- Clarify footnote c: modify footnote (c) to provide specificity regarding the use of the term “controlled interruption” of load.
- Require the applicable entities to define and document the proxies necessary to simulate cascading outages; and
- Tailor the purpose statement to reflect the specific goal of the Reliability, as discussed above.

FERC Staff Report

- Same as TPL-001 & 002

Version 0 Industry Comments

- Same as TPL-001 & 002
- TO should provide plan of action
- Don't base penalties on low probability, low consequence events
- Use NERC Compliance Reporting Process
- Clearly identify outages

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

VRF Comment

- Time horizon should be long-term planning
- R2 – lack of consistency with TPL-001 & TPL-002
- R2.1 - lack of consistency with TPL-001
- R2.1.1 - lack of consistency with TPL-001 & TPL-004
- R2.1.2 - lack of consistency with TPL-001 & TPL-005
- R2.1.3 - lack of consistency with TPL-001 & TPL-006
- R2.2 - lack of consistency with TPL-001 & TPL-007

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-001 through TPL-006 Technical Issues List

TPL-004:

FERC NOPR

- Require that critical system conditions be determined in the same manner as proposed for TPL-001-0;
- Require the identification of options for reducing the probability or impacts of extreme events that cause cascading;
- Require that, in determining the range of extreme events to be assessed, the contingency list of Category D be expanded to include recent events; and
- Tailor the purpose statement to reflect the specific goal of the Reliability Standard.

FERC Staff Report

- Need to reduce the probability of loss of multiple elements and mitigating impact
- Share assessments
- Need to be more severe than weather
- Same as TPL-001

Version 0 Industry Comments

- Same as TPL-001
- Perform analysis on credible contingency
- R1.3.9 – remove from extreme events
- TO should determine which events to study

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-005:

FERC NOPR

- Commission will not propose any action on TPL-005-0, as it applies only to regional reliability organizations.
- The term and extent of assessment, as well as the study years, are not appropriately defined; the process for determining load levels needs to be standardized; and local area networks and system adjustments need to be specifically defined.

Regional Fill-in-the-Blank Team Comments

- New SAR needed

Version 0 Industry Comments

- Define fuel adequacy
- An RRO can't make a mandatory request for another RRO to perform a study

TPL-006:

FERC NOPR

- Commission will not propose any action on TPL-006-0, as it applies only to regional reliability organizations.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

Please use this form to submit comments on the proposed SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans. Comments must be submitted by **March 16, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "TPL Supplement SAR" in the subject line. If you have questions please contact Ed Dobrowolski at ed.dobrowoski@nerc.net or by telephone at 609-452-8060.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

Background Information

This SAR is intended to supplement the already-approved SAR for Assess Transmission Future Needs and Develop Transmission Plans dated April 30, 2006. The Assess Transmission Future Needs and Develop Transmission Plans SAR includes revisions to TPL-001 through TPL-004 with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments.

The supplementary SAR would expand the scope of the original SAR to include TPL-005 and TPL-006 and upgrade the entire set of standards (TPL-001 through TPL-006) to conform to the latest version of the Reliability Standards Procedure Development and the ERO Rules of Procedure.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The intent is to comprehensively address all necessary revisions to the entire set of TPL Standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments:

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments:

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comments:

February 15, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Three 30-day Comment Periods Open

The Standards Committee (SC) announces the following standards actions:

SAR to Amend the Assess Transmission Future Needs and Develop Transmission Plans SAR Posted for 30-day Comment Period February 15–March 16, 2007

The SAR to amend the already-approved SAR for Assess Transmission Future Needs and Develop Transmission Plans ([Project 2006-02](#)) proposes to add TPL-005-0 and TPL-006-0 to the list of transmission planning standards currently addressed (TPL-001 through TPL-004), to consider issues raised by FERC and stakeholders regarding this set of standards, and to bring the entire set of standards into conformance with the ERO Rules of Procedure and the latest version of the Reliability Standards Development Procedure. Please use the [comment form](#) to provide comments on this SAR amendment.

First Standard (MOD-001-1) in the Series of ATC/TTC/AFC Revisions Posted for 30-day Comment Period February 15–March 16, 2007

The first standard modified under [Project 2006-07](#), MOD-001-1 — ATC and AFC Calculation Methodologies, requires the Transmission Service Provider to document and use a single methodology for calculating ATC or AFC. The drafting team is soliciting comments on the proposed requirements before developing the measures and compliance elements. Please use the [comment form](#) to provide comments on this draft standard's proposed requirements.

Second Draft of SAR for Backup Facilities Posted for 30-day Comment Period February 15–March 16, 2007

The SAR for [Project 2006-04](#) proposes modifying EOP-008-0 — Plans for Loss of Control Center Functionality. The revisions to EOP-008 focus on ensuring the continuation of functionality needed for reliable system operation regardless of the manner in which it is achieved. The modifications will consider issues raised by FERC and stakeholders about this standard, and will bring the standard into conformance with the ERO Rules of Procedure and the latest version of the Reliability Standards Development Procedure. Please use the [comment form](#) to provide comments on this SAR.

Standards Development Process

The [Reliability Standards Development Procedure](#) contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

Background Information

This SAR is intended to supplement the already-approved SAR for Assess Transmission Future Needs and Develop Transmission Plans dated April 30, 2006. The Assess Transmission Future Needs and Develop Transmission Plans SAR includes revisions to TPL-001 through TPL-004 with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments.

The supplementary SAR would expand the scope of the original SAR to include TPL-005 and TPL-006 and upgrade the entire set of standards (TPL-001 through TPL-006) to conform to the latest version of the Reliability Standards Procedure Development and the ERO Rules of Procedure.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The intent is to comprehensively address all necessary revisions to the entire set of TPL Standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments:

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: Considering the current scope, the Std DT should be encouraged to consider a major re-write of TPL-001 thru TPL-006, possibly including a restructuring into a single standard rather than the present multiple standards.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments: I recommend that you clarify that these lists of items in Appendix B are topics to consider, not topics that must be included. Also, I recommend that any standards requirements that are evident as Good Utility Practice or procedural in nature be retired as requirements, but retained in the form of reference documents, operating guidelines, or some other similar form that will be available to any industry participant that wishes to use them.

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: Please also see my response to Question #1.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments: I believe that most of the additional information contained in the draft 'supplemental' SAR is valuable and will assist the SDT in addressing the various stakeholder concerns. I am concerned with conflicting information addressed below.

I am not familiar with the concept of a supplemental SAR and am not sure if there are going to be two SARs now, or if this new effort supercedes the existing SAR. This is especially a concern when there appear to be differences between them regarding functional applicabilities and principles, as well as the expansion of scope.

I understand the Standards Development Procedure to require the original SAR to be modified, when it states, "If the standard drafting team determines it is necessary to expand the scope of the standard or to modify the scope in a way that is no longer consistent with the scope defined in the SAR, then the drafting team may initiate or recommend another requestor initiate a new SAR (Step 1) to develop the expanded or modified scope. At no time will a drafting team develop a standard that is not within the scope of the SAR that was authorized for development."

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: The approved SAR is of type 'New Standard' while the supplemental SAR type is not, but rather, 'Revision to existing Standards' as well as, 'Withdraw of existing Standard (possible)'.

Regarding the Reliability Function Applicabilities, the supplemental SAR does not include the Reliability Authority or the Planning Authority which were included in the approved SAR, and the supplemental SAR includes the Resource Planner and Generation Owner functions, which are not included in the approved SAR. I believe that the Planning Authority needs to be addressed in terms of the FERC NOPR discussion, summarized on pages B3 and B4 of the supplemental SAR.

The supplemental SAR includes item 7 in the Applicable Reliability Principles, while the approved SAR does not.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

If there are going to be two SARs then I believe that the supplemental SAR should include the previously approved SAR in the 'Related SARs' section on page 7.

The concise summaries of the Version 0 Industry comments are appreciated, but these should be made more clear in that these will probably become key to any actual changes to planning contingencies. For example, it is not clear what, 'Address deliverability of generation to load' means. Also, does, 'Don't include generation runback or redispatch' mean that this shouldn't be addressed or that the standard should be worded to specifically not include them. Other terms such as, 'Don't include planning outage', and 'single terminals are not included' should also be more thoroughly described.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments:

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments:

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

Background Information

This SAR is intended to supplement the already-approved SAR for Assess Transmission Future Needs and Develop Transmission Plans dated April 30, 2006. The Assess Transmission Future Needs and Develop Transmission Plans SAR includes revisions to TPL-001 through TPL-004 with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments.

The supplementary SAR would expand the scope of the original SAR to include TPL-005 and TPL-006 and upgrade the entire set of standards (TPL-001 through TPL-006) to conform to the latest version of the Reliability Standards Procedure Development and the ERO Rules of Procedure.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The intent is to comprehensively address all necessary revisions to the entire set of TPL Standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Yes

No

Comments:

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: We do not support a long-term planning standards applying to RCs. The NERC functional model is very clear that RCs are operational entities. Is the intent to replace RRO with RC for the fill-in-the-blank standards? That would be an inappropriate solution. A more appropriate solution would be to consider replacing the RRO with the planning coordinator.

We also do not understand how a transmission planning standard could apply to the additional functional entities: Transmission Owner and Generator Owner.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments: The original SAR did a good job of capturing many of the reliability improvements necessary to the TPL Standards. Now that additional information is available from the various stakeholder groups and drafting teams, it is clear that additional reliability-related improvements to the Standards can be made. It is not clear how to quantify the additional improvement the supplemental SAR will make to the existing Standard Drafting effort, but certainly there are additional reliability improvements to be made to each of the subject Standards.

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: Standard Drafting Teams should not be responding so heavily to comments made by FERC in a NOPR. The NOPR is just that ... "Proposed." There may be additional changes required as a result of the final Rule. The final Rule may even negate some of the proposed changes made in the NOPR. If the drafting team thinks that FERC hit on a good idea for improvement, then it would be appropriate for inclusion in the Standard, but simply to make changes to a Standard because an idea surfaced in a Proposed Rule is premature.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments: Manitoba Hydro believes the planning standards should ensure that complete and consistent assessments are conducted by the responsible entities.

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: Manitoba Hydro agrees in principle with the expanded scope, but believes that this scope should be a part of the Standards Development Procedures manual so all stakeholders have a voice in the requirements in Appendix A. We have some concern that the SAR gives the drafting team the power to add additional improvements beyond the SAR as this provides an opportunity for SDT members to forward specific owner agendas.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comments: The SAR should considering adding a requirements to the standards to mandate tests for robustness by doing sensitivity to critical system parameters such as load growth rate, load power factor, etc. to provide insight into the margin between the operating point and unacceptable performance. There should also be a specific requirement to assess reactive power adequacy, voltage stability and system damping.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments: As the standards are written now, all of the requirements apply to both the Transmission Planner and Planning Authority. The NERC Functional Model Version 3 replaced the Planning Authority with the Planning Coordinator. The standards should reflect this change as well as the division of responsibilities between Transmission Planner and Planning Coordinator in the functional model.

Additionally, they should seek to clarify the relationship between Transmission Planner and Planning Coordinator. How many transmission planners can there be per Planning Coordinator. Can there be overlapping Planning Coordinators?

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: We do not support a long-term planning standards applying to RCs. The NERC functional model is very clear that RCs are operational entities. Is the intent to replace RRO with RC for the fill-in-the-blank standards? That would be an inappropriate solution. A more appropriate solution would be to consider replacing the RRO with the planning coordinator.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

Background Information

This SAR is intended to supplement the already-approved SAR for Assess Transmission Future Needs and Develop Transmission Plans dated April 30, 2006. The Assess Transmission Future Needs and Develop Transmission Plans SAR includes revisions to TPL-001 through TPL-004 with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments.

The supplementary SAR would expand the scope of the original SAR to include TPL-005 and TPL-006 and upgrade the entire set of standards (TPL-001 through TPL-006) to conform to the latest version of the Reliability Standards Procedure Development and the ERO Rules of Procedure.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The intent is to comprehensively address all necessary revisions to the entire set of TPL Standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments:

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments:

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments: The planning of the transmission system is critical to the reliability of the transmission system. Additional details provided to all stakeholders are crucial to ensure that transmission is built in a timely manner to protect the reliability of the system. Also, by making the process and information available to all stakeholders, you ensure that everyone's interest is heard in the process and not just the large transmission owner/operators, but all users of the transmission system. The assumptions used in the evaluation process must be vetted by all stakeholders as they are the critical drivers on what transmission is needed and when it is needed.

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: These are transmission planning standards and as such, should only apply to TPs, not RP, TO and GO entities. Certainly, information must be provided from the TOs and GOs on their facilities to be able to run the planning studies, but the MOD standards should cover this obligation. And RC are operating entities and not planning entities.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comments: This should be more than enough to try to get into these transmission planning standards.

Comments:

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comments:

SDG&E believes that there are additional revisions that need to be incorporated into this set of standards.

The Supplemental SAR dated January 17, 2007, has an Appendix B that summarizes issues to be resolved in this new set of standards. Those issues are a collection of comments from FERC NOPR, FERC Staff Report, Industrial comments on version 0, Phase III/IV, etc.

In order to develop a set of reliability standards for transmission planners, SDG&E believes there are a few more issues to be addressed and/or clarified in this set of standards.

1. Critical System Conditions

These "Critical System Conditions" are referring to system conditions to be studied for the transmission planning. Typically, entities deem several system conditions as critical on the basis of accumulative institutional knowledge.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

However, in recent FERC NOPR, FERC directs industry to conduct sensitivity studies to identify these critical system conditions and document the sensitivity studies. The sensitivity factors in FERC's direction include load power factors, generation retirements, generation dispatch, transaction patterns, controllable loads, demand side management, transmission outages.

As those will result in extensive scope of study, we would like to see this set of standards clearly answer following questions:

- a. How often do we required to perform such sensitivity studies to identify critical system conditions?
- b. Do we check those sensitivity factors one by one to find the worst, or do we define the worst combination as the critical? Or
- c. Do we continue to leave the "critical system conditions" determination to study performer's discretion?

2. Contingencies

In Appendix B of the latest Supplementary SAR for TPL standards, comments and modification requests were summarized. Contingencies for planning studies is one of critical elements. This can be split into three issues and SDG&E provides following comments for each of them:

a. Study all contingencies

One of the comments suggests to study "all contingencies". Clearly, "All contingencies" need to be clarified. The additional workload incurred due to the dismissal of planners' accumulative institutional knowledge may be unreasonable.

b. Study non-common mode contingencies

The issue regarding reasonable workload also applies to the "non-common mode" contingencies. The non-common mode refers to combination of unrelated elements, say one 230 kV line in CFE (Mexico) and other 230 kV line in Alberta, Canada, as one contingency. This too needs clarification.

c. Study event-based contingencies

Evaluating the impact of "event-based" contingencies makes sense. However, translating an event, such as an earthquake, into a list of elements to be taken out for power flow and stability computer simulation, will need clear guidelines.

3. "Identification of options for reducing the probability or impacts of extreme events that cause cascading"

This is a direct quote of FERC's directed modification in its NOPR.

a. If the impacts only need to be identified with conceptual methods, how do we maintain "consistency" among entities?

b. If FERC intends to request the entities to identify the probability/impacts with quantitative methods, then there is a long list of issues to be addressed before a transmission planner could in reality perform such an analysis:

- How to define "cascading" in system simulation analysis.
- Reasonable and feasible probabilistic variables need to be defined. For instance, in addition to the equipment failure as probabilistic variable, other probabilistic variables need to be considered to meet FERC's direction, such as hurricanes, fires, earthquakes, lightning, flooding, landslides and even an airplane falling into a critical substation, and so on.
- Regional efforts need to be taken to develop a probabilistic methodology and probabilistic database that can be applied uniformly so entities can be treated equally.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

- Regional efforts need to be taken to guide selection and/or development of probabilistic analysis software tools. Such tools have to be ready for transmission planners to use and derive quantified solutions.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

Background Information

This SAR is intended to supplement the already-approved SAR for Assess Transmission Future Needs and Develop Transmission Plans dated April 30, 2006. The Assess Transmission Future Needs and Develop Transmission Plans SAR includes revisions to TPL-001 through TPL-004 with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments.

The supplementary SAR would expand the scope of the original SAR to include TPL-005 and TPL-006 and upgrade the entire set of standards (TPL-001 through TPL-006) to conform to the latest version of the Reliability Standards Procedure Development and the ERO Rules of Procedure.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The intent is to comprehensively address all necessary revisions to the entire set of TPL Standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Please review the SAR and then answer the questions on the following page. Please submit the completed form by e-mail to sarcomm@nerc.com with the words “TPL Supplement SAR” in the subject line by **March 16, 2007**.

Comment Form — SAR to Supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Yes

No

Comments:

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the "Standard Review Forms" attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Yes

No

Comments: We do not support a long-term planning standards applying to RCs. The NERC functional model is very clear that RCs are operational entities. Is the intent to replace RRO with RC for the fill-in-the-blank standards? That would be an inappropriate solution. A more appropriate solution would be to consider replacing the RRO with the planning coordinator.

We also do not understand how a transmission planning standard could apply to the additional functional entities: Transmission Owner and Generator Owner.

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Yes

No

Comments:

Consideration of Comments on 1st Posting of SAR to Supplement the Assess Transmission Future Needs SAR

The Supplemental Assess Transmission Future Needs SAR Drafting Team thanks all commenters who submitted comments on the Supplemental Assess Transmission Future Needs SAR. This SAR was posted for a 30-day public comment period from February 15 through March 16, 2007. The requesters asked stakeholders to provide feedback on the standard through a special standard Comment Form. There were 16 sets of comments, including comments from 42 different people associated with more than 37 companies or organizations representing 8 of the 10 Industry Segments as shown in the table on the following pages.

Based on the comments received, the drafting team is recommending that the Standards Committee approve the Supplemental SAR to be moved forward to the standards drafting stage of the process.

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easy to see the responses associated with each question. All comments received on the standards can be viewed in their original format at:

<http://www.nerc.com/~filez/standards/Assess-Transmission-Future-Needs.html>

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.¹

No changes were made to the SAR based on received comments. The only changes that were made to the SAR at this time were to add references and appropriate supporting material to address the FERC Order 693 and to update the attachment to reflect the latest version of the Standard Review Guidelines.

¹ The appeals process is in the Reliability Standards Development Procedures: <http://www.nerc.com/standards/newstandardsprocess.html>.

Consideration of Comments on 1st Posting of SAR to Supplement the Assess Transmission Future Needs SAR

The Industry Segments are:

- 1 — Transmission Owners
- 2 — RTOs, ISOs
- 3 — Load-serving Entities
- 4 — Transmission-dependent Utilities
- 5 — Electric Generators
- 6 — Electricity Brokers, Aggregators, and Marketers
- 7 — Large Electricity End Users
- 8 — Small Electricity End Users
- 9 — Federal, State, Provincial Regulatory or other Government Entities
- 10 — Regional Reliability Organizations, Regional Entities

Index to Questions, Comments, and Responses

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR? 5

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? 8

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?12

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

1. Do you believe that there is a reliability-related need to provide additional detail, including specific issues for consideration, to the requirements in this set of standards as proposed in this supplemental SAR?

Summary Consideration: All respondents agreed with the statement. The affirmative responses that included comments mainly dealt with procedural issues as opposed to content. The SAR DT believes that we have answered those concerns in the provided responses and that no additional changes to the SAR are required.

Question #1			
Commenter	Yes	No	Comment
Exelon	<input checked="" type="checkbox"/>		<p>I believe that most of the additional information contained in the draft 'supplemental' SAR is valuable and will assist the SDT in addressing the various stakeholder concerns. I am concerned with conflicting information addressed below.</p> <p>I am not familiar with the concept of a supplemental SAR and am not sure if there are going to be two SARs now, or if this new effort supercedes the existing SAR. This is especially a concern when there appear to be differences between them regarding functional applicabilities and principles, as well as the expansion of scope.</p> <p>I understand the Standards Development Procedure to require the original SAR to be modified, when it states, "If the standard drafting team determines it is necessary to expand the scope of the standard ot to modify the scope in a way that is no longer consistent with the scope defined in the SAR, then the drafting team may initiate or recommend another requestor initiate a new SAR (Step 1) to develop the expanded or modified scope. At no time will a drafting team develop a standard that is not within the scope of the SAR that was authorized for development."</p>
<p>Response: The SDT recognized that the scope of the original SAR needed to be broadened to encompass changes in the industry since the approval of the original SAR. We decided to use the concept of a supplement rather than completely re-writing the original SAR. These are not intended to be two distinct SARs. The Supplemental SAR is intended to be a true supplement to the original SAR in every sense of the word.</p>			
ODEC	<input checked="" type="checkbox"/>		<p>The planning of the transmission system is critical to the reliability of the transmission system. Additional details provided to all stakeholders are crucial to ensure that transmission is built in a timley manner to protect the reliability of the system. Also, by making the process and information available to all stakeholders, you ensure that everyone's interest is heard in the process and not just the large transmission owner/operators, but all users of the transmission system. The assumptions used in the evaluation process must be vetted by all stakeholders as they are the critical drivers on what transmission is needed and when it is needed.</p>
<p>Response: Stakeholders will receive their opportunity to vet the assumptions used in the evaluation process during comment</p>			

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

Question #1			
Commenter	Yes	No	Comment
and balloting of the standards.			
ERCOT	<input checked="" type="checkbox"/>		I recommend that you clarify that these lists of items in Appendix B are topics to consider, not topics that must be included. Also, I recommend that any standards requirements that are evident as Good Utility Practice or procedural in nature be retired as requirements, but retained in the form of reference documents, operating guidelines, or some other similar form that will be available to any industry participant that wishes to use them.
Response: The following excerpt is from point #3 of the Supplemental SAR Purpose Statement – "... <u>consider</u> the items mentioned in the Technical Issues Lists prepared by the NERC staff..." (emphasis added). The intent was always to consider the issues and not to make them necessarily mandatory changes. The comment on good utility practice and procedural requirements will be passed on to the SDT. Please note that Appendix B as it was included in the Supplemental SAR was prepared prior to the final FERC Order. Directions included with that Order must be specifically addressed in the standards drafting process.			
MISO	<input checked="" type="checkbox"/>		As the standards are written now, all of the requirements apply to both the Transmission Planner and Planning Authority. The NERC Functional Model Version 3 replaced the Planning Authority with the Planning Coordinator. The standards should reflect this change as well as the division of responsibilities between Transmission Planner and Planning Coordinator in the functional model. Additionally, they should seek to clarify the relationship between Transmission Planner and Planning Coordinator. How many transmission planners can their be per Planning Coordinator. Can there be overlapping Planning Coordinators?
Response: Functional Model v3 will be used as the reference. Your comment and questions will be passed on to the SDT.			
ITC Transmission	<input checked="" type="checkbox"/>		The original SAR did a good job of capturing many of the reliability improvements necessary to the TPL Standards. Now that additional information is available from the various stakeholder groups and drafting teams, it is clear that additional reliability-related improvements to the Standards can be made. It is not clear how to quantify the additional improvement the supplemental SAR will make to the existing Standard Drafting effort, but certainly there are additional reliability improvements to be made to each of the subject Standards.
Response: Agreed.			
Manitoba Hydro	<input checked="" type="checkbox"/>		Manitoba Hydro believes the planning standards should ensure that complete and consistent assessments are conducted by the responsible entities.
Response: Agreed.			
AEP	<input checked="" type="checkbox"/>		

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

Question #1			
Commenter	Yes	No	Comment
HQT	<input checked="" type="checkbox"/>		
IESO	<input checked="" type="checkbox"/>		
ISO New England	<input checked="" type="checkbox"/>		
KCPL	<input checked="" type="checkbox"/>		
MRO	<input checked="" type="checkbox"/>		
NPCC CP9 Working Group	<input checked="" type="checkbox"/>		
NYISO	<input checked="" type="checkbox"/>		
San Diego Gas & Electric	<input checked="" type="checkbox"/>		
IRC Standards Review Committee	<input checked="" type="checkbox"/>		

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

2. Do you agree with the expanded scope of the proposed project as set forth in this supplemental SAR? (The scope includes all the items noted on the “Standard Review Forms” attached to the SAR as well as other improvements to the standards that meet the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards. Please consider these items as non-mandatory and only for consideration by the drafting team.)

Summary Consideration: The majority of respondents agreed to the proposition. The negative opinions ranged from procedural matters to items that dealt with providing the SDT with sufficient flexibility to do their job or issues that are more appropriately addressed at the standards drafting stage. In particular, there was concern that some of the applicable entities checked on the supplementary SAR were not appropriate. The SAR DT felt that the Transmission Owner & Generator Owner might potentially provide data that could come into play for some of the requirements in TPL-005 & 006. The SAR DT wanted to provide maximum flexibility to the SDT so these entities as well as the Reliability Coordinator were included. However they are only for consideration and not mandatory. The SAR DT believes that we have addressed these concerns in the responses provided and that no additional changes to the SAR are required.

Question #2			
Commenter	Yes	No	Comment
Exelon		<input checked="" type="checkbox"/>	<p>The approved SAR is of type 'New Standard' while the supplemental SAR type is not, but rather, 'Revision to existing Standards' as well as, 'Withdraw of existing Standard (possible)'.</p> <p>Regarding the Reliability Function Applicabilities, the supplemental SAR does not include the Reliability Authority or the Planning Authority which were included in the approved SAR, and the supplemental SAR includes the Resource Planner and Generation Owner functions, which are not included in the approved SAR. I believe that the Planning Authority needs to be addressed in terms of the FERC NOPR discussion, summarized on pages B3 and B4 of the supplemental SAR.</p> <p>The supplemental SAR includes item 7 in the Applicable Reliability Principles, while the approved SAR does not.</p> <p>If there are going to be two SARs then I believe that the supplemental SAR should include the previously approved SAR in the 'Related SARs' section on page 7.</p> <p>The concise summaries of the Version 0 Industry comments are appreciated, but these should be made more clear in that these will probably become key to any actual changes to planning contingencies. For example, it is not clear what, 'Address deliverability of generation to load' means. Also, does, 'Don't include generation runback or redispatch'</p>

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

Question #2			
Commenter	Yes	No	Comment
			mean that this shouldn't be addressed or that the standard should be worded to specifically not include them. Other terms such as, 'Don't include planning outage', and 'single terminals are not included' should also be more thoroughly described.
<p>Response: The SDT recognized that the scope of the original SAR needed to be broadened to encompass changes in the industry since the approval of the original SAR. We decided to use the concept of a supplement rather than completely re-writing the original SAR. These are not intended to be two distinct SARs. The Supplemental SAR is intended to be a true supplement to the original SAR in every sense of the word. The full text of all comments referenced in the Supplemental SAR Appendix B has been made available to the SDT so that there should be no confusion as to the intent or meaning of the comment.</p>			
ODEC		<input checked="" type="checkbox"/>	These are transmission planning standards and as such, should only apply to TPs, not RP, TO and GO entities. Certainly, information must be provided from the TOs and GOs on their facilities to be able to run the planning studies, but the MOd standards should cover this obligation. And RC are operating entities and not planning entities.
<p>Response: The SAR DT felt that the TO & GO might potentially provide data that could come into play for some of the requirements in TPL-005 & 006. The SAR DT wanted to provide maximum flexibility to the SDT so these entities as well as the RC were included. However they are only for consideration and not mandatory. Your comments will be passed on to the SDT.</p>			
ISO New England		<input checked="" type="checkbox"/>	<p>We do not support a long-term planning standards applying to RCs. The NERC functional model is very clear that RCs are operational entities. Is the intent to replace RRO with RC for the fill-in-the-blank standards? That would be an inappropriate solution. A more appropriate solution would be to consider replacing the RRO with the planning coordinator.</p> <p>We also do not understand how a transmission planning standard could apply to the additional functional entities: Transmission Owner and Generator Owner.</p>
<p>Response: The SAR DT felt that the TO & GO might potentially provide data that could come into play for some of the requirements in TPL-005 & 006. Commenter	Yes	No	Comment
requirements in TPL-005 & 006. The SAR DT wanted to provide maximum flexibility to the SDT so these entities as well as the RC were included. However they are only for consideration and not mandatory. Your comments will be passed on to the SDT.			
NYISO		<input checked="" type="checkbox"/>	It is unclear as to what obligations the RC, TO, and GO would have in a long-term planning standard. The NERC functional model is very clear that RCs are operational entities. The RC, TO, GO, should not have a direct obligation in the process, but should be a resource for input into the process.
Response: The SAR DT felt that the TO & GO might potentially provide data that could come into play for some of the requirements in TPL-005 & 006. The SAR DT wanted to provide maximum flexibility to the SDT so these entities as well as the RC were included. However they are only for consideration and not mandatory. Your comments will be passed on to the SDT.			
IRC Standards Review Committee		<input checked="" type="checkbox"/>	We do not support a long-term planning standards applying to RCs. The NERC functional model is very clear that RCs are operational entities. Is the intent to replace RRO with RC for the fill-in-the-blank standards? That would be an inappropriate solution. A more appropriate solution would be to consider replacing the RRO with the planning coordinator. We also do not understand how a transmission planning standard could apply to the additional functional entities: Transmission Owner and Generator Owner.
Response: The SAR DT felt that the TO & GO might potentially provide data that could come into play for some of the requirements in TPL-005 & 006. The SAR DT wanted to provide maximum flexibility to the SDT so these entities as well as the RC were included. However they are only for consideration and not mandatory. Your comments will be passed on to the SDT.			
ITC Transmission		<input checked="" type="checkbox"/>	Standard Drafting Teams should not be responding so heavily to comments made by FERC in a NOPR. The NOPR is just that ... "Proposed." There may be additional changes required as a result of the final Rule. The final Rule may even negate some of the proposed changes made in the NOPR. If the drafting team thinks that FERC hit on a good idea for improvement, then it would be appropriate for inclusion in the Standard, but simply to make changes to a Standard because an idea surfaced in a Proposed Rule is premature.
Response: The following excerpt is from point #3 of the Supplemental SAR Purpose Statement – "... <i>consider</i> the items mentioned in the Technical Issues Lists prepared by the NERC staff..." (emphasis added). The intent was always to consider the issues and not to make them necessarily mandatory changes. Directions included with the FERC Final Order must be specifically addressed in the standards drafting process.			
AEP	<input checked="" type="checkbox"/>		Considering the current scope, the Std DT should be encouraged to consider a major re-write of TPL-001 thru TPL-006, possibly including a restructuring into a single standard

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

Question #2			
Commenter	Yes	No	Comment
			rather than the present multiple standards.
Response: We agree with the general concept and the SDT will be provided with this option.			
Manitoba Hydro	<input checked="" type="checkbox"/>		Manitoba Hydro agrees in principle with the expanded scope, but believes that this scope should be a part of the Standards Development Procedures manual so all stakeholders have a voice in the requirements in Appendix A. We have some concern that the SAR gives the drafting team the power to add additional improvements beyond the SAR as this provides an opportunity for SDT members to forward specific owner agendas.
Response: The material in Appendix A is excerpted from the Reliability Standards Development Work Plan 2007 – 2009 that was reviewed and approved by the Standards Committee. As stated, it represents general guidelines and not mandatory changes for the revision of existing standards. Stakeholders will receive their opportunity to vet the assumptions used in the evaluation process during comment and balloting of the standards.			
ERCOT	<input checked="" type="checkbox"/>		Please also see my response to Question #1.
Response: Please see the response to your comment on question #1.

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

3. Do you think that there are any additional revisions that should be incorporated into this set of standards, beyond those that have already been identified in the April 30, 2006 version of the original SAR and this supplemental SAR?

Summary Consideration: Only two respondents suggested revisions. In both cases the comments are more appropriately addressed at the standards drafting stage. The SAR DT believes that we have satisfactorily addressed the expressed concerns with the provided responses and that no additional changes to the SAR are required.

Question #3			
Commenter	Yes	No	Comment
Manitoba Hydro	<input checked="" type="checkbox"/>		The SAR should considering adding a requirements to the standards to mandate tests for robustness by doing sensitivity to critical system parameters such as load growth rate, load power factor, etc., to provide insight into the margin between the operating point and unacceptable performance. There should also be a specific requirement to assess reactive power adequacy, voltage stability and system damping.
Response: The SAR DT is aware of the interest in these items. The scope of both the original and supplemental SARs allows these items to be incorporated in the standards drafting process. We will pass your comments on to the SDT.			
San Diego Gas & Electric	<input checked="" type="checkbox"/>		<p>SDG&E believes that there are additional revisions that need to be incorporated into this set of standards.</p> <p>The Supplemental SAR dated January 17, 2007, has an Appendix B that summarizes issues to be resolved in this new set of standards. Those issues are a collection of comments from FERC NOPR, FERC Staff Report, Industrial comments on version 0, Phase III/IV, etc.</p> <p>In order to develop a set of reliability standards for transmission planners, SDG&E believes there are a few more issues to be addressed and/or clarified in this set of standards.</p> <p>1. Critical System Conditions These "Critical System Conditions" are referring to system conditions to be studied for the transmission planning. Typically, entities deem several system conditions as critical on the basis of accumulative institutional knowledge.</p> <p>However, in recent FERC NOPR, FERC directs industry to conduct sensitivity studies to identify these critical system conditions and document the sensitivity studies. The sensitivity factors in FERC's direction include load power factors, generation</p>

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

Question #3			
Commenter	Yes	No	Comment
			<p>retirements, generation dispatch, transaction patterns, controllable loads, demand side management, transmission outages.</p> <p>As those will result in extensive scope of study, we would like to see this set of standards clearly answer following questions:</p> <ol style="list-style-type: none"> a. How often do we required to perform such sensitivity studies to identify critical system conditions? b. Do we check those sensitivity factors one by one to find the worst, or do we define the worst combination as the critical? Or c. Do we continue to leave the "critical system conditions" determination to study performer's discretion? <p>2. Contingencies In Appendix B of the latest Supplementary SAR for TPL standards, comments and modification requests were summarized. Contingencies for planning studies is one of critical elements. This can be split into three issues and SDG&E provides following comments for each of them:</p> <ol style="list-style-type: none"> a. Study all contingencies One of the comments suggests to study "all contingencies". Clearly, "All contingencies" need to be clarified. The additional workload incurred due to the dismissal of planners' accumulative institutional knowledge may be unreasonable. b. Study non-common mode contingencies The issue regarding reasonable workload also applies to the "non-common mode" contingencies. The non-common mode refers to combination of unrelated elements, say one 230 kV line in CFE (Mexico) and other 230 kV line in Alberta, Canada, as one contingency. This too needs clarification. c. Study event-based contingencies Evaluating the impact of "event-based" contingencies makes sense. However, translating an event, such as an earthquake, into a list of elements to be taken out for power flow and stability computer simulation, will need clear guidelines. <p>3. "Identification of options for reducing the probability or impacts of extreme events that cause cascading" This is a direct quote of FERC's directed modification in its NOPR.</p>

Consideration of Comments on Supplemental Assess Transmission Future Needs SAR

Question #3			
Commenter	Yes	No	Comment
			<p>a. If the impacts only need to be identified with conceptual methods, how do we maintain "consistency" among entities?</p> <p>b. If FERC intends to request the entities to identify the probability/impacts with quantitative methods, then there is a long list of issues to be addressed before a transmission planner could in reality perform such an analysis:</p> <ul style="list-style-type: none"> • How to define "cascading" in system simulation analysis. • Reasonable and feasible probabilistic variables need to be defined. For instance, in addition to the equipment failure as probabilistic variable, other probabilistic variables need to be considered to meet FERC's direction, such as hurricanes, fires, earthquakes, lightening, flooding, landslides and even an airplane falling into a critical substation, and so on. • Regional efforts need to be taken to develop a probabilistic methodology and probabilistic database that can be applied uniformly so entities can be treated equally. • Regional efforts need to be taken to guide selection and/or development of probabilistic analysis software tools. Such tools have to be ready for transmission planners to use and derive quantified solutions.
<p>Response: The following excerpt is from point #3 of the Supplemental SAR Purpose Statement – "...<u>consider</u> the items mentioned in the Technical Issues Lists prepared by the NERC staff..." (emphasis added). The intent was always to consider the issues and not to make them necessarily mandatory changes. Directions included with the FERC Final Order must be specifically addressed in the standards drafting process. The Supplemental SAR was intended to be a true supplement to the original SAR in every sense of the word. The SAR DT is aware of the interest in these items. The scope of both the original and supplemental SARs allows these items to be incorporated in the standards drafting process. We will pass your comments on to the SDT. We refer the commenter to the NERC web site for previous meeting notes and comments concerning related issues.</p>			
ODEC		<input checked="" type="checkbox"/>	This should be more than enough to try to get into these transmission planning standards.
<p>Response: Most stakeholders who commented seemed to agree with you.</p>

1/17/07 Standard Authorization Request Form

Title of Proposed Project: Revisions to TPL-001 through TPL-006, Transmission System Performance and Assessment (This SAR is intended to supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans dated 4/30/06 in support of Standards Project 2006-02.)	
Request Date	January 17, 2007
<u>Revised</u>	<u>April 5, 2006</u>

SAR Requestor Information	SAR Type <i>(Check a box for each one that applies.)</i>
Name Assess Transmission Future Needs Standard Drafting Team	<input type="checkbox"/> New Standard
Primary Contact Robert Millard – Vice-Chair, ATFNSTD	<input checked="" type="checkbox"/> Revision to existing Standards
Telephone (708) 588-9886 Fax none	<input checked="" type="checkbox"/> Withdrawal of existing Standard (possible)
E-mail bob.millard@rfirst.org	<input type="checkbox"/> Urgent Action

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

This SAR is intended to supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans dated 4/30/06 in support of Standards Project 2006-02.

The revisions to the following standards would improve technical clarity and address concerns identified by stakeholders and FERC:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Revisions to TPL-001 through TPL-004 are already underway (Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team) with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments. The expansion of the work already underway with TPL-001 through TPL-004 will focus on the general improvements to the standard identified through the attached *Appendix A: Reliability Standard Review Guidelines* and the FERC and stakeholder concerns identified in the attached *Appendix B: TPL-001 through TPL-006 Technical Issues List*.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The purpose of modifying this set of standards is to:

1. Provide an adequate level of reliability for the North American bulk power systems — ensure each of the standards is complete and the requirements are set at an appropriate level to ensure reliability.
2. Ensure each of the standards is enforceable as a mandatory reliability standard with financial penalties — the applicability to bulk power system owners, operators, and users, and as appropriate particular classes of facilities, is clearly defined; the purpose, requirements, and measures are results-focused and unambiguous; the consequences of violating the requirements are clear.
3. Make general improvements using the Reliability Standard Review Guidelines and consider the items mentioned in the Technical Issues Lists prepared by the NERC staff which attempt to capture comments from the:
 - FERC NOPR (Docket # RM06-16-00 dated October 20, 2006) ,
 - FERC staff report dated May 11, 2006 concerning NERC standards submitted with ERO application,

Standards Authorization Request Form

- Version 0 and Phase 3&4 standards development (see note 1),
- Violations Risk Factors (VRF) drafting team (see note 1),
- Regional Fill-in-the-Blank Team (RRSWG – a NERC working group involved with regional standards development), and
- Draft SAR for Planning Authority

The SDT should also consider any other issues that were not completely captured but were stated or referenced in the above materials.

Directions extracted from FERC Order 693, 890 and other applicable orders and any possible future subsequent revisions will be addressed by the SDT.

Note 1: Comments received from the industry during public postings of the TPL subject matter were sometimes outside the work being posted or outside the drafting team's scope and were not reflected in the drafting of the final work product. These should now be considered by this SDT.

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

The six standards in this set are all Version 0 standards. As the ERO begins enforcing compliance with reliability standards under Section 215 of the Federal Power Act in the United States and applicable statutes and regulations in Canada, the industry needs a set of clear, measurable, and enforceable reliability standards. The Version 0 standards, while a good foundation, were translated from historical operating and planning policies and guides that were appropriate in an era of voluntary compliance. The Version 0 standards and recent updates were put in place as a temporary starting point to start-up the ERO and begin enforcement of mandatory standards. However, it is important to update the standards in a timely manner, incorporating improvements to make the standards more suitable for enforcement and to capture prior recommendations that were deferred during the Version 0 translation and any subsequent standards development that have implications to the TPL standards.

Standards Authorization Request Form

Brief Description: (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

The proposed work effort will address three main issues:

1. Conformance to the new rules and regulations brought about by Section 215 of the Federal Power Act and the creation of the ERO,
2. Supplement the approved work of the existing ATFNSDT to include the necessary revisions to TPL-005 & TPL-006, and
3. Address technical issues raised by FERC and industry stakeholders.

Standards Authorization Request Form

Reliability Functions

The Standard will Apply to the Following Functions <i>(Check box for each one that applies.)</i>		
<input checked="" type="checkbox"/>	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
<input type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
<input type="checkbox"/>	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
<input checked="" type="checkbox"/>	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
<input checked="" type="checkbox"/>	Resource Planner	Develops a (>one year) plan for the resource adequacy of its specific loads within its portion of a Planning Coordinator area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
<input type="checkbox"/>	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
<input checked="" type="checkbox"/>	Transmission Owner	Owns and maintains transmission facilities.
<input type="checkbox"/>	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
<input type="checkbox"/>	Distribution Provider	Delivers electrical energy to the End-use customer.
<input checked="" type="checkbox"/>	Generator Owner	Owns and maintains generating facilities.
<input type="checkbox"/>	Generator Operator	Operates generation unit(s) to provide real and reactive power.
<input type="checkbox"/>	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
<input type="checkbox"/>	Market Operator	Interface point for reliability functions with commercial functions.
<input checked="" type="checkbox"/>	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Standards Authorization Request Form

Reliability and Market Interface Principles

Applicable Reliability Principles <i>(Check box for all that apply.)</i>	
<input checked="" type="checkbox"/>	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input type="checkbox"/>	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
<input type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
<input type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
<input checked="" type="checkbox"/>	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
Does the proposed Standard comply with all of the following Market Interface Principles? <i>(Select 'yes' or 'no' from the drop-down box.)</i>	
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes	
2. An Organization Standard shall not give any market participant an unfair competitive advantage. Yes	
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes	
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes	
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes	

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft a standard based on this description.)

This SAR expands on the work already underway with the Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team, by requiring that TPL-001 through TPL-006 be upgraded in accordance with the Reliability Standards Development Plan 2007 – 2009. These revisions include the following:

This SAR will be appended to the already approved SAR for Assess Transmission Future Needs and Develop Transmission Plans and will include modifications to all of the following standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

The revisions would improve technical clarity and address concerns identified by stakeholders and FERC. The drafting team will focus on the general improvements to the standards and use as a starting point for the expanded work the subject matter identified in *Appendix A: Reliability Standard Review Guidelines* and the FERC and stakeholder concerns identified in *Appendix B: TPL-001 through TPL-006 Technical Issues List*.

The expanded scope also will include elimination of the ‘fill-in-the-blank’ elements of TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004. The standards need to be modified or retired to address the “fill-in-the blank” components. If the ‘fill-in-the-blank’ requirements are addressed through the contractual arrangements each Region has with the ERO, TPL-005 and TPL-006 could be retired.

The drafting team must ensure that there is consistency in the requirements across the set of TPL standards

The overall development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards, using the attached, Reliability Standard Review Guidelines. In addition, the drafting team will need to make conforming changes to standards impacted by changes made to these six standards.

Appendix A: Reliability Standard Review Guidelines

Applicability

Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose

Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements

Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability

Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations

Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness

Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

Reliability Standard Review Guidelines

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements

In general, requirements for entities to have ‘capabilities’ (this would include facilities for communication, agreements with other entities, etc.), should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to ‘maintain’ their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a ‘unique’ definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the ‘verb list’ from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

This is a requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

Or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

~~Mitigation~~ Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replaces the existing 'levels of non-compliance.')

The violation severity levels may be applied for each requirement ~~or~~ and may be combined to cover multiple requirements, as long as it is clear which requirements are included and that all requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — the responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions** — the responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.

Reliability Standard Review Guidelines

- **High: marginal performance or results** — the responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results** — the responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with '~~Electric Reliability Organization~~Regional Entity'

~~Bulk Electric System~~

Replace, '~~Bulk Electric System~~' with '~~bulk power system~~'

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Appendix B: TPL-001 through TPL-006 Technical Issues List

Excerpted from NERC Reliability Standards Development Plan: 2007 - 2009

TPL-001

FERC NOPR

- Require that critical system conditions be determined by conducting sensitivity studies; (*Not necessarily "cook book" but what are the processes someone reasonably skilled in the art would follow.*)
- Require that system conditions and contingencies assessed be reviewed by neighboring systems; (*Looking for coordination with neighboring systems*)
- Modify Requirement R1.3 to substitute the reference to regional reliability organization with Regional Entity;
- Require consideration of planned outages of critical equipment; and
- Modify footnote (a): footnote (a) to Table 1 requires clarification. The NERC Transmission Issues Subcommittee (TIS) 325 recommended that footnote (a) be modified to state explicitly that emergency ratings apply to Category B and C (contingency conditions) and not to Category A (system intact). The Commission proposes that footnote (a) be modified in the revised Reliability Standard as recommended by TIS and that the normal facility rating be in accordance with Reliability Standard FAC-008-1 and normal voltages be in accordance with Reliability Standard VAR-001-1.

FERC Staff Report

- Only for normal
- Doesn't consider planned outages
- Clarify footnote 'a' & 'b' in table
- Stress system during simulations
- Include sensitivity studies
- Include extreme events

Version 0 Industry Comments

- Several semantic issues
- Clarify timing for submittal of corrective plan
- Clarify use of applicable ratings in Table 1, note 'a'
- Need to address deliverability to load
- Define critical system conditions
- Allow for engineering judgment in setting conditions for power flow
- Do planned facilities include just those under construction?
- Need to include multiple time frames
- What is a major load center?
- Table 1 – C.5 goes beyond double circuit outage criteria
- Table 1, items 6, 7, 8 & 9 need footnote stating that they do not apply to generator breaker failure
- Table 1, note 'b' – clarify when to curtail firm deliveries

TPL-001 through TPL-006 Technical Issues List

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

Violation Risk Factors (VRF) Drafting Team Comment

- R1 – time horizon should be long-term planning

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-002:

FERC NOPR

- Require that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- Require the inclusion of the reliability impact of the entities' existing spare equipment strategy; (*Only looking for consideration of spare equipment that has a long lead time such as a transformer*)
- Explicitly require all generators to ride through the same set of Category B and C contingencies as required for wind generators in Order No. 661; (*Document explicit definition of ride through capability for generators*)
- Require documentation of load models used in system studies and supporting rationale for their use;
- Clarify the phrase "permit operating steps necessary to maintain system control;" and
- Clarify footnote (b): modify footnote (b) to state that load shedding for a single contingency is not permitted except in very special circumstances where such interruption is limited to the firm load associated with the failure (consequential load loss).³³⁰ For purposes of clarity, the Commission proposes to require that the phrase "to prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power transfers" be deleted from footnote (b). This statement is more appropriate for Category C events and is already captured by footnote (c) to Table 1, which is applicable to Category C events.

FERC staff report

- Only includes loss of single element
- NERC TIS Report recommendations not addressed

Version 0 Industry Comments

- Define critical system conditions
- Clarify timing for corrective plan
- Address deliverability of generation to load
- Clarify applicable ratings in Table 1, note 'a'
- Don't include generation runback or re-dispatch
- Must study all contingencies and multiple demand levels & time frames
- Don't include planning outage
- Single terminals are not included

Phase III/IV comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

VRF comments

- Time horizon should be long-term planning and R2.2 – redundant with R1.3.8

Comment from draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-001 through TPL-006 Technical Issues List

TPL-003:

FERC NOPR

- Require that critical system conditions be determined by conducting sensitivity studies (as elaborated in our discussion of TPL-001-0);
- Clarify footnote c: modify footnote (c) to provide specificity regarding the use of the term “controlled interruption” of load.
- Require the applicable entities to define and document the proxies necessary to simulate cascading outages; and
- Tailor the purpose statement to reflect the specific goal of the Reliability, as discussed above.

FERC Staff Report

- Same as TPL-001 & 002

Version 0 Industry Comments

- Same as TPL-001 & 002
- TO should provide plan of action
- Don't base penalties on low probability, low consequence events
- Use NERC Compliance Reporting Process
- Clearly identify outages

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

VRF Comment

- Time horizon should be long-term planning
- R2 – lack of consistency with TPL-001 & TPL-002
- R2.1 - lack of consistency with TPL-001
- R2.1.1 - lack of consistency with TPL-001 & TPL-004
- R2.1.2 - lack of consistency with TPL-001 & TPL-005
- R2.1.3 - lack of consistency with TPL-001 & TPL-006
- R2.2 - lack of consistency with TPL-001 & TPL-007

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-001 through TPL-006 Technical Issues List

TPL-004:

FERC NOPR

- Require that critical system conditions be determined in the same manner as proposed for TPL-001-0;
- Require the identification of options for reducing the probability or impacts of extreme events that cause cascading;
- Require that, in determining the range of extreme events to be assessed, the contingency list of Category D be expanded to include recent events; and
- Tailor the purpose statement to reflect the specific goal of the Reliability Standard.

FERC Staff Report

- Need to reduce the probability of loss of multiple elements and mitigating impact
- Share assessments
- Need to be more severe than weather
- Same as TPL-001

Version 0 Industry Comments

- Same as TPL-001
- Perform analysis on credible contingency
- R1.3.9 – remove from extreme events
- TO should determine which events to study

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-005:

FERC NOPR

- Commission will not propose any action on TPL-005-0, as it applies only to regional reliability organizations.
- The term and extent of assessment, as well as the study years, are not appropriately defined; the process for determining load levels needs to be standardized; and local area networks and system adjustments need to be specifically defined.

Regional Fill-in-the-Blank Team Comments

- New SAR needed

Version 0 Industry Comments

- Define fuel adequacy
- An RRO can't make a mandatory request for another RRO to perform a study

TPL-001 through TPL-006 Technical Issues List

TPL-006:

FERC NOPR

- Commission will not propose any action on TPL-006-0, as it applies only to regional reliability organizations.

|

Excerpts from FERC Order 693
TPL Standards

TPL-001-0

1770. Accordingly, the Commission approves Reliability Standard TPL-001-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-001-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions and study years be determined by conducting sensitivity studies with due consideration of the range of factors outlined above;
- (2) requires a peer review of planning assessments with neighboring entities;
- (3) modifies Requirement R1.3 to substitute the reference to regional reliability organization with Regional Entity;
- (4) requires assessments of outages of critical long lead time equipment, consistent with the entity's spare equipment strategy and
- (5) address the concerns regarding footnote (a) of Table 1, including the applicability of emergency ratings and consistency of normal ratings and voltages with values obtained from other Reliability Standards and the concerns raised by International Transmission in regard to the footnotes in Table 1.

TPL-002-0

1797. Accordingly, the Commission approves Reliability Standard TPL-002-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-002-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- (2) requires assessments of planned outages of long lead time critical equipment consistent with the entity's spare equipment strategy;
- (3) requires all generators to ride through the same set of Category B and C contingencies as required by wind generators in Order No. 661, or to simulate those generators that cannot ride through as tripping;
- (4) requires documentation of load models used in system studies and supporting rationale for their use;
- (5) clarifies the phrase "permit operating steps necessary to maintain system control" in footnote (a) and the use of emergency ratings and
- (6) clarifies footnote (b) in regard to load loss following a single contingency, specifying the amount and duration of consequential load loss and system adjustments permitted after the first contingency to return the system to a normal operating state, as discussed above.

TPL-003-0

1825. Accordingly, the Commission approves Reliability Standard TPL-003-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-003-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- (2) modifies footnote (c) to Table 1 to clarify the term “controlled load interruption;”
- (3) requires applicable entities to define and document the proxies necessary to simulate cascading outages and
- (4) tailors the purpose statement to reflect the specific goal of the Reliability Standard.

TPL-004-0

1836. Accordingly, the Commission approves Reliability Standard TPL-004-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-004-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions be determined in the same manner as proposed for TPL-001-0;
- (2) requires the identification of options for reducing the probability or impacts of extreme events that cause cascading;
- (3) requires that, in determining the range of extreme events to be assessed, the contingency list of Category D be expanded to include recent events and
- (4) tailors the purpose statement to reflect the specific goal of the Reliability Standard.

TPL-005-0

1840. Consistent with our discussion in the Common Issues section above, we will not approve or remand TPL-005-0 until we receive additional information from the ERO.

1841. In Order No. 890, the Commission stated that there will be a series of technical conferences and regional meetings to obtain industry input to achieving the goal of regional planning. The Commission encourages the ERO to monitor those proceedings and use the results as input to the Reliability Standards development process in revising Reliability Standard TPL-005-0 to address regional planning and related processes.

TPL-006-0

1845. Consistent with our discussion in the Common Issues section above, the Commission will not approve or remand TPL-006-0.

1/17/07 Standard Authorization Request Form

Title of Proposed Project: Revisions to TPL-001 through TPL-006, Transmission System Performance and Assessment (This SAR is intended to supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans dated 4/30/06 in support of Standards Project 2006-02.)	
Request Date	January 17, 2007
Revised	April 5, 2006

SAR Requestor Information	SAR Type <i>(Check a box for each one that applies.)</i>
Name Assess Transmission Future Needs Standard Drafting Team	<input type="checkbox"/> New Standard
Primary Contact Robert Millard – Vice-Chair, ATFNSTD	<input checked="" type="checkbox"/> Revision to existing Standards
Telephone (708) 588-9886 Fax none	<input checked="" type="checkbox"/> Withdrawal of existing Standard (possible)
E-mail bob.millard@rfirst.org	<input type="checkbox"/> Urgent Action

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

This SAR is intended to supplement the SAR for Assess Transmission Future Needs and Develop Transmission Plans dated 4/30/06 in support of Standards Project 2006-02.

The revisions to the following standards would improve technical clarity and address concerns identified by stakeholders and FERC:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

Revisions to TPL-001 through TPL-004 are already underway (Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team) with the primary focus to clarify the associated Table 1, Transmission System Standards – Normal and Emergency Conditions, used to identify the criteria for system assessments. The expansion of the work already underway with TPL-001 through TPL-004 will focus on the general improvements to the standard identified through the attached *Appendix A: Reliability Standard Review Guidelines* and the FERC and stakeholder concerns identified in the attached *Appendix B: TPL-001 through TPL-006 Technical Issues List*.

TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004, need to be modified or retired to address the “fill-in-the blank” components and establish requirements within the standards or through a contractual arrangement as to which entity should perform and provide the subject assessment and data. If these requirements are addressed through the delegation agreements each Region has with the Electric Reliability Organization (ERO), TPL-005 and TPL-006 could be retired.

The purpose of modifying this set of standards is to:

1. Provide an adequate level of reliability for the North American bulk power systems — ensure each of the standards is complete and the requirements are set at an appropriate level to ensure reliability.
2. Ensure each of the standards is enforceable as a mandatory reliability standard with financial penalties — the applicability to bulk power system owners, operators, and users, and as appropriate particular classes of facilities, is clearly defined; the purpose, requirements, and measures are results-focused and unambiguous; the consequences of violating the requirements are clear.
3. Make general improvements using the Reliability Standard Review Guidelines and consider the items mentioned in the Technical Issues Lists prepared by the NERC staff which attempt to capture comments from the:
 - FERC NOPR (Docket # RM06-16-00 dated October 20, 2006) ,
 - FERC staff report dated May 11, 2006 concerning NERC standards submitted with ERO application,

Standards Authorization Request Form

- Version 0 and Phase 3&4 standards development (see note 1),
- Violations Risk Factors (VRF) drafting team (see note 1),
- Regional Fill-in-the-Blank Team (RRSWG – a NERC working group involved with regional standards development), and
- Draft SAR for Planning Authority

The SDT should also consider any other issues that were not completely captured but were stated or referenced in the above materials.

Directions extracted from FERC Order 693, 890 and other applicable orders and any possible future subsequent revisions will be addressed by the SDT.

Note 1: Comments received from the industry during public postings of the TPL subject matter were sometimes outside the work being posted or outside the drafting team's scope and were not reflected in the drafting of the final work product. These should now be considered by this SDT.

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

The six standards in this set are all Version 0 standards. As the ERO begins enforcing compliance with reliability standards under Section 215 of the Federal Power Act in the United States and applicable statutes and regulations in Canada, the industry needs a set of clear, measurable, and enforceable reliability standards. The Version 0 standards, while a good foundation, were translated from historical operating and planning policies and guides that were appropriate in an era of voluntary compliance. The Version 0 standards and recent updates were put in place as a temporary starting point to start-up the ERO and begin enforcement of mandatory standards. However, it is important to update the standards in a timely manner, incorporating improvements to make the standards more suitable for enforcement and to capture prior recommendations that were deferred during the Version 0 translation and any subsequent standards development that have implications to the TPL standards.

Standards Authorization Request Form

Brief Description: (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

The proposed work effort will address three main issues:

1. Conformance to the new rules and regulations brought about by Section 215 of the Federal Power Act and the creation of the ERO,
2. Supplement the approved work of the existing ATFNSDT to include the necessary revisions to TPL-005 & TPL-006, and
3. Address technical issues raised by FERC and industry stakeholders.

Standards Authorization Request Form

Reliability Functions

The Standard will Apply to the Following Functions <i>(Check box for each one that applies.)</i>		
<input checked="" type="checkbox"/>	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
<input type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
<input type="checkbox"/>	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
<input checked="" type="checkbox"/>	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
<input checked="" type="checkbox"/>	Resource Planner	Develops a (>one year) plan for the resource adequacy of its specific loads within its portion of a Planning Coordinator area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
<input type="checkbox"/>	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
<input checked="" type="checkbox"/>	Transmission Owner	Owns and maintains transmission facilities.
<input type="checkbox"/>	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
<input type="checkbox"/>	Distribution Provider	Delivers electrical energy to the End-use customer.
<input checked="" type="checkbox"/>	Generator Owner	Owns and maintains generating facilities.
<input type="checkbox"/>	Generator Operator	Operates generation unit(s) to provide real and reactive power.
<input type="checkbox"/>	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
<input type="checkbox"/>	Market Operator	Interface point for reliability functions with commercial functions.
<input checked="" type="checkbox"/>	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Standards Authorization Request Form

Reliability and Market Interface Principles

Applicable Reliability Principles <i>(Check box for all that apply.)</i>	
<input checked="" type="checkbox"/>	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input type="checkbox"/>	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
<input type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
<input type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
<input checked="" type="checkbox"/>	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
Does the proposed Standard comply with all of the following Market Interface Principles? <i>(Select 'yes' or 'no' from the drop-down box.)</i>	
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes	
2. An Organization Standard shall not give any market participant an unfair competitive advantage. Yes	
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes	
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes	
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes	

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft a standard based on this description.)

This SAR expands on the work already underway with the Assess Transmission Future Needs and Develop Transmission Plans Standard Drafting Team, by requiring that TPL-001 through TPL-006 be upgraded in accordance with the Reliability Standards Development Plan 2007 – 2009. These revisions include the following:

This SAR will be appended to the already approved SAR for Assess Transmission Future Needs and Develop Transmission Plans and will include modifications to all of the following standards:

- TPL-001 — System Performance under Normal Conditions
- TPL-002 — System Performance Following Loss of a Single BES Element
- TPL-003 — System Performance Following Loss of Two or More BES Elements
- TPL-004 — System Performance Following Extreme BES Events
- TPL-005 — Regional and Interregional Self-Assessment Reliability Reports
- TPL-006 — Data from the Regional Reliability Organization Needed to Assess Reliability

The revisions would improve technical clarity and address concerns identified by stakeholders and FERC. The drafting team will focus on the general improvements to the standards and use as a starting point for the expanded work the subject matter identified in *Appendix A: Reliability Standard Review Guidelines* and the FERC and stakeholder concerns identified in *Appendix B: TPL-001 through TPL-006 Technical Issues List*.

The expanded scope also will include elimination of the ‘fill-in-the-blank’ elements of TPL-005 and TPL-006, which require regional and inter-regional assessments based on the system performance requirements stated in TPL-001 through TPL-004. The standards need to be modified or retired to address the “fill-in-the blank” components. If the ‘fill-in-the-blank’ requirements are addressed through the contractual arrangements each Region has with the ERO, TPL-005 and TPL-006 could be retired.

The drafting team must ensure that there is consistency in the requirements across the set of TPL standards

The overall development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards, using the attached, Reliability Standard Review Guidelines. In addition, the drafting team will need to make conforming changes to standards impacted by changes made to these six standards.

Appendix A: Reliability Standard Review Guidelines

Applicability

Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose

Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements

Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability

Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations

Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness

Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

Reliability Standard Review Guidelines

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements

In general, requirements for entities to have ‘capabilities’ (this would include facilities for communication, agreements with other entities, etc.), should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to ‘maintain’ their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a ‘unique’ definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the ‘verb list’ from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

This is a requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

Or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replaces the existing 'levels of non-compliance.')

The violation severity levels may be applied for each requirement and may be combined to cover multiple requirements, as long as it is clear which requirements are included and that all requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — the responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions** — the responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.

Reliability Standard Review Guidelines

- **High: marginal performance or results** — the responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results** — the responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor

Replace, ‘Regional Reliability Organization’ with ‘Regional Entity

Fill-in-the-blank Requirements

Do not include any ‘fill-in-the-blank’ requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, ‘Associated Documents’.

Appendix B: TPL-001 through TPL-006 Technical Issues List

Excerpted from NERC Reliability Standards Development Plan: 2007 - 2009

TPL-001

FERC NOPR

- Require that critical system conditions be determined by conducting sensitivity studies; (*Not necessarily "cook book" but what are the processes someone reasonably skilled in the art would follow.*)
- Require that system conditions and contingencies assessed be reviewed by neighboring systems; (*Looking for coordination with neighboring systems*)
- Modify Requirement R1.3 to substitute the reference to regional reliability organization with Regional Entity;
- Require consideration of planned outages of critical equipment; and
- Modify footnote (a): footnote (a) to Table 1 requires clarification. The NERC Transmission Issues Subcommittee (TIS) 325 recommended that footnote (a) be modified to state explicitly that emergency ratings apply to Category B and C (contingency conditions) and not to Category A (system intact). The Commission proposes that footnote (a) be modified in the revised Reliability Standard as recommended by TIS and that the normal facility rating be in accordance with Reliability Standard FAC-008-1 and normal voltages be in accordance with Reliability Standard VAR-001-1.

FERC Staff Report

- Only for normal
- Doesn't consider planned outages
- Clarify footnote 'a' & 'b' in table
- Stress system during simulations
- Include sensitivity studies
- Include extreme events

Version 0 Industry Comments

- Several semantic issues
- Clarify timing for submittal of corrective plan
- Clarify use of applicable ratings in Table 1, note 'a'
- Need to address deliverability to load
- Define critical system conditions
- Allow for engineering judgment in setting conditions for power flow
- Do planned facilities include just those under construction?
- Need to include multiple time frames
- What is a major load center?
- Table 1 – C.5 goes beyond double circuit outage criteria
- Table 1, items 6, 7, 8 & 9 need footnote stating that they do not apply to generator breaker failure
- Table 1, note 'b' – clarify when to curtail firm deliveries

TPL-001 through TPL-006 Technical Issues List

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

Violation Risk Factors (VRF) Drafting Team Comment

- R1 – time horizon should be long-term planning

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-001 through TPL-006 Technical Issues List

TPL-002:

FERC NOPR

- Require that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- Require the inclusion of the reliability impact of the entities' existing spare equipment strategy; (*Only looking for consideration of spare equipment that has a long lead time such as a transformer*)
- Explicitly require all generators to ride through the same set of Category B and C contingencies as required for wind generators in Order No. 661; (*Document explicit definition of ride through capability for generators*)
- Require documentation of load models used in system studies and supporting rationale for their use;
- Clarify the phrase "permit operating steps necessary to maintain system control;" and
- Clarify footnote (b): modify footnote (b) to state that load shedding for a single contingency is not permitted except in very special circumstances where such interruption is limited to the firm load associated with the failure (consequential load loss).³³⁰ For purposes of clarity, the Commission proposes to require that the phrase "to prepare for the next contingency, system adjustments are permitted, including curtailments of contracted Firm (non-recallable reserved) electric power transfers" be deleted from footnote (b). This statement is more appropriate for Category C events and is already captured by footnote (c) to Table 1, which is applicable to Category C events.

FERC staff report

- Only includes loss of single element
- NERC TIS Report recommendations not addressed

Version 0 Industry Comments

- Define critical system conditions
- Clarify timing for corrective plan
- Address deliverability of generation to load
- Clarify applicable ratings in Table 1, note 'a'
- Don't include generation runback or re-dispatch
- Must study all contingencies and multiple demand levels & time frames
- Don't include planning outage
- Single terminals are not included

Phase III/IV comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

VRF comments

- Time horizon should be long-term planning and R2.2 – redundant with R1.3.8

Comment from draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-001 through TPL-006 Technical Issues List

TPL-003:

FERC NOPR

- Require that critical system conditions be determined by conducting sensitivity studies (as elaborated in our discussion of TPL-001-0);
- Clarify footnote c: modify footnote (c) to provide specificity regarding the use of the term “controlled interruption” of load.
- Require the applicable entities to define and document the proxies necessary to simulate cascading outages; and
- Tailor the purpose statement to reflect the specific goal of the Reliability, as discussed above.

FERC Staff Report

- Same as TPL-001 & 002

Version 0 Industry Comments

- Same as TPL-001 & 002
- TO should provide plan of action
- Don't base penalties on low probability, low consequence events
- Use NERC Compliance Reporting Process
- Clearly identify outages

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

VRF Comment

- Time horizon should be long-term planning
- R2 – lack of consistency with TPL-001 & TPL-002
- R2.1 - lack of consistency with TPL-001
- R2.1.1 - lack of consistency with TPL-001 & TPL-004
- R2.1.2 - lack of consistency with TPL-001 & TPL-005
- R2.1.3 - lack of consistency with TPL-001 & TPL-006
- R2.2 - lack of consistency with TPL-001 & TPL-007

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-001 through TPL-006 Technical Issues List

TPL-004:

FERC NOPR

- Require that critical system conditions be determined in the same manner as proposed for TPL-001-0;
- Require the identification of options for reducing the probability or impacts of extreme events that cause cascading;
- Require that, in determining the range of extreme events to be assessed, the contingency list of Category D be expanded to include recent events; and
- Tailor the purpose statement to reflect the specific goal of the Reliability Standard.

FERC Staff Report

- Need to reduce the probability of loss of multiple elements and mitigating impact
- Share assessments
- Need to be more severe than weather
- Same as TPL-001

Version 0 Industry Comments

- Same as TPL-001
- Perform analysis on credible contingency
- R1.3.9 – remove from extreme events
- TO should determine which events to study

Phase III/IV Comments

- Add a requirement to verify that there are sufficient reactive resources
- Add a requirement to identify where UVLS should be installed

Comment from Draft SAR on Planning Authority

- Provide clarity where the Planning Authority is mentioned

TPL-005:

FERC NOPR

- Commission will not propose any action on TPL-005-0, as it applies only to regional reliability organizations.
- The term and extent of assessment, as well as the study years, are not appropriately defined; the process for determining load levels needs to be standardized; and local area networks and system adjustments need to be specifically defined.

Regional Fill-in-the-Blank Team Comments

- New SAR needed

Version 0 Industry Comments

- Define fuel adequacy
- An RRO can't make a mandatory request for another RRO to perform a study

TPL-001 through TPL-006 Technical Issues List

TPL-006:

FERC NOPR

- Commission will not propose any action on TPL-006-0, as it applies only to regional reliability organizations.

**Excerpts from FERC Order 693
TPL Standards**

TPL-001-0

1770. Accordingly, the Commission approves Reliability Standard TPL-001-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-001-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions and study years be determined by conducting sensitivity studies with due consideration of the range of factors outlined above;
- (2) requires a peer review of planning assessments with neighboring entities;
- (3) modifies Requirement R1.3 to substitute the reference to regional reliability organization with Regional Entity;
- (4) requires assessments of outages of critical long lead time equipment, consistent with the entity's spare equipment strategy and
- (5) address the concerns regarding footnote (a) of Table 1, including the applicability of emergency ratings and consistency of normal ratings and voltages with values obtained from other Reliability Standards and the concerns raised by International Transmission in regard to the footnotes in Table 1.

TPL-002-0

1797. Accordingly, the Commission approves Reliability Standard TPL-002-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-002-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- (2) requires assessments of planned outages of long lead time critical equipment consistent with the entity's spare equipment strategy;
- (3) requires all generators to ride through the same set of Category B and C contingencies as required by wind generators in Order No. 661, or to simulate those generators that cannot ride through as tripping;
- (4) requires documentation of load models used in system studies and supporting rationale for their use;
- (5) clarifies the phrase "permit operating steps necessary to maintain system control" in footnote (a) and the use of emergency ratings and
- (6) clarifies footnote (b) in regard to load loss following a single contingency, specifying the amount and duration of consequential load loss and system adjustments permitted after the first contingency to return the system to a normal operating state, as discussed above.

TPL-003-0

1825. Accordingly, the Commission approves Reliability Standard TPL-003-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-003-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions be determined in the same manner as we propose to require for TPL-001-0;
- (2) modifies footnote (c) to Table 1 to clarify the term “controlled load interruption;”
- (3) requires applicable entities to define and document the proxies necessary to simulate cascading outages and
- (4) tailors the purpose statement to reflect the specific goal of the Reliability Standard.

TPL-004-0

1836. Accordingly, the Commission approves Reliability Standard TPL-004-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to TPL-004-0 through the Reliability Standards development process that:

- (1) requires that critical system conditions be determined in the same manner as proposed for TPL-001-0;
- (2) requires the identification of options for reducing the probability or impacts of extreme events that cause cascading;
- (3) requires that, in determining the range of extreme events to be assessed, the contingency list of Category D be expanded to include recent events and
- (4) tailors the purpose statement to reflect the specific goal of the Reliability Standard.

TPL-005-0

1840. Consistent with our discussion in the Common Issues section above, we will not approve or remand TPL-005-0 until we receive additional information from the ERO.

1841. In Order No. 890, the Commission stated that there will be a series of technical conferences and regional meetings to obtain industry input to achieving the goal of regional planning. The Commission encourages the ERO to monitor those proceedings and use the results as input to the Reliability Standards development process in revising Reliability Standard TPL-005-0 to address regional planning and related processes.

TPL-006-0

1845. Consistent with our discussion in the Common Issues section above, the Commission will not approve or remand TPL-006-0.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Version 1 of SAR posted for comment from April 2, 2002 through May 3, 2002.
2. Version 2 of SAR posted for comment from May 5, 2004 through June 5, 2004.
3. Version 3 of SAR posted on November 18, 2005.
4. SAR approved on April 30, 2006.
5. Version 1 of Supplemental SAR posted for comment from February 15, 2007 through March 16, 2007.
6. Version 2 of Supplemental SAR posted on April 9, 2007.
7. Version 1 of revised standard(s) posted for comment on September 17, 2007.

Proposed Action Plan and Description of Current Draft:

The SDT has established an aggressive schedule of meetings and conference calls that allows for steady progress through the standards development process in anticipation of completing their assignment in 2Q08. The current draft is the first iteration of the revision of existing standards TPL-001 through TPL-006 and includes one revised standard, TPL-001-1, replacing TPL-001-0, TPL-002-0, TPL-003-0 and TPL-004-0. TPL-005 & -006 will be addressed later in the project. Violation Risk Factors, Time Horizons, Measures, Compliance and Implementation Plans will be included in subsequent postings.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Respond to comments from first posting of standard(s) and submit revision 1 of the standard(s).	4Q2007
2. Respond to comments from second posting of standard(s) and submit revision 2 of the standard(s).	4Q2007
3. Submit revision 3 of the standard(s) for balloting.	4Q2007
4. Submit standard(s) for recirculation balloting.	2Q2008
5. Submit standard(s) to BOT.	2Q2008
6.	
7.	

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect Facility Ratings.

Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.

Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.

Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.

Near-Term Transmission Planning Horizon: Transmission planning period that covers Years One through five.

Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.

Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.

Planning Events: Events which require Transmission system performance requirements to be met.

Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.

System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.

Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**
2. **Number:** **TPL-001-1**
3. **Purpose:** Establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.
4. **Applicability:**
 - 4.1. **Functional Entity**
 - 4.1.1. Planning Coordinator.
 - 4.1.2. Transmission Planner.
 - 4.1.3. Resource Planner.
 - 4.1.4. Load-Serving Entity.
 - 4.1.5. Transmission Owner.
 - 4.1.6. Generator Owner.
5. **Effective Date:** TBD

B. Requirements

- R1. Each Resource Planner, Transmission Planner, Transmission Owner, Generator Owner, and Load-Serving Entity shall each provide its respective Planning Coordinator with the following modeling information required for System performance studies upon request (within 30 calendar days) : [*Violation Risk Factor: TBD*] [*Time Horizon: TBD*]
 - R1.1. Load forecasts adhering, at a minimum, to the following criteria:
 - R1.1.1. Use of expected Load mix based on the actual or expected aggregate mix of industrial, commercial, and residential Loads.
 - R1.1.2. Based on normal weather patterns as agreed to by the Planning Coordinator(s) and the Transmission Planner(s) for the area(s) of their responsibility.
 - R1.1.3. Identification of Demand Side Management (DSM) Load reductions consistent with operational requirements.
 - R1.2. Load models with supporting rationale that include power factor data based on historical System performance, validated by measurement during stressed System conditions, or documented Transmission planning area requirements.
 - R1.3. Firm transfers/Interchange Schedules and resources required to supply Load for each Balancing Authority.
 - R1.4. Known planned outages and long-term outages for Transmission and generation equipment including protective relays with consideration given to spare equipment strategy.

R1.5. Planned Facilities defined in accordance with the documented criteria of the Planning Coordinator, including but not limited to: Transmission Lines, generators, circuit breakers, Reactive Power devices, Protection System equipment and control devices, and new technologies.

R2. Each Transmission Planner and Planning Coordinator shall conduct and document the results of its annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or past studies, and shall cover steady state analyses, short circuit analyses, and Stability analyses including both System and plant Stability.
[Violation Risk Factor: TBD] [Time Horizon: TBD]

R2.1. The steady state portion of the Near-Term Transmission Planning Horizon Planning Assessment shall address all five years of the assessment period and be supported at a minimum by the following annual current studies,, supplemented with qualified past studies as shown in Requirement R2.6:

R2.1.1. System peak Load for either Year One or year two, and year five.

R2.1.2. System Off-Peak Load for one of the five years.

R2.1.3. For each of the studies described in Requirement R2.1.1 and Requirement R2.1.2, sensitivity case(s) that stress the System with sensitivities that reflect one or more of the following conditions shall be run and documentation with the rationale for the selected sensitivity(ies) shall be supplied:

R.2.1.3.1. Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.

R.2.1.3.2. Modification of expected transfers.

R.2.1.3.3. Unavailability of long lead time facilities.

R.2.1.3.4. Variability and outages of reactive resources.

R.2.1.3.5. Generation additions, retirements, or other dispatch scenarios.

R.2.1.3.6. Decreased effectiveness of controllable Loads and Demand Side Management.

R.2.1.3.7. Modification of planned Transmission outages.

R2.2. For the steady state portion of the Long-Term Transmission Planning Horizon Planning Assessment, at a minimum, a current System peak Load study is required annually for one of the years in the assessment period to support the annual Planning Assessment.

R2.2.1. To accommodate any known longer lead time projects that may take longer than ten years to complete, the Planning Assessment shall be extended accordingly.

R2.3. The short circuit portion of the Planning Assessment shall be conducted annually and supported by current or past studies.

- R2.3.1.** A current study shall be performed if changes in the BES result in increased fault currents such as resource additions and other Facility changes that result in reductions in impedance.
- R2.4.** The System Stability portion of the Near-Term Transmission Planning Horizon Planning Assessment shall address all five years of the assessment period, and be supported by current or past studies. The following studies are required:
 - R2.4.1.** System peak Load for one of the five years. For peak System Load levels, the Load model shall include the dynamic effects of induction motor Loads.
 - R2.4.2.** System Off-Peak Load for one of the five years.
 - R2.4.3.** Sensitivity case(s) that stress the System to reflect one or more of the following conditions shall be run with documentation provided explaining the rationale for the selected sensitivity(ies):
 - R.2.4.3.1.** Variations in Load model assumptions.
 - R.2.4.3.2.** Expected simultaneous transfers including non-firm transfers.
 - R.2.4.3.3.** Unavailability of long lead time facilities.
 - R.2.4.3.4.** Reactive dispatch of generators and other reactive power devices.
 - R.2.4.3.5.** Generation additions, retirements, or other dispatch scenarios.
- R2.5.** The plant Stability portion of the Planning Assessment shall be analyzed consistent with Requirement R4.6 with studies for the year when the following occur:
 - R2.5.1.** New generator(s) are added or generation modifications are made such as increasing generation capability, replacing the exciter or addition of a power System stabilizer.
 - R2.5.2.** Material changes in the electrical vicinity of existing generation are made such as the addition or removal of a Transmission Line at or near the point of Interconnection.
- R2.6.** Past studies may be used to support the Planning Assessment if they meet the following requirements:
 - R2.6.1.** For steady state analysis: if the study is less than three years old and no material changes have occurred to the System in the intervening period. Material changes include topology changes, generation additions/removals, and market structure changes.
 - R2.6.2.** For short circuit analysis: if the study is less than five years old and no material changes have occurred to the System in the intervening period.
 - R2.6.3.** For plant and System Stability analysis: until material changes in the System make the study no longer valid. Material changes in the system include the addition of a Transmission Line or a generator.

- R2.7.** For Planning Events shown in Table 1 – Steady State Performance and Table 2 – Stability Performance, when the analysis indicates an inability of the System to meet the performance requirements in the tables, the Planning Assessment shall include Corrective Action Plans addressing how the performance requirements will be met. Revisions to the Corrective Action Plans are allowed over time but shall meet the performance requirements in the tables. Such plans shall:
- R2.7.1.** Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of interim Operating Procedures.
 - R.2.7.1.1.** For the Near-Term Transmission Planning Horizon, include both a project initiation date as well as an in-service date.
 - R.2.7.1.2.** For the Long-Term Transmission Planning Horizon, provide an in-service year..
 - R2.7.2.** Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables.
 - R2.7.3.** Include documentation of the criteria for determining committed and proposed projects, with all projects identified as either, ‘committed’ or ‘proposed.’
 - R2.7.4.** Not remove committed projects without documentation to show that the revised plan meets the performance requirements.
 - R2.7.5.** Be reviewed in subsequent annual Planning Assessments as to implementation status of identified System Facilities and Operating Procedures.
- R3.** For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform analysis for the Near-Term and Long-Term Transmission Planning Horizon studies in Requirement R2.1 and Requirement R2.2. The studies shall be based on computer power flow simulations that analyze BES normal performance (n-0) and System response to contingencies in Table 1 – Steady State Performance. [*Violation Risk Factor: TBD*] [*Time Horizon: TBD*]
- R3.1.** Studies shall determine whether the BES meets the performance requirements in Table 1 – Steady State Performance.
 - R3.2.** Contingency analyses shall simulate the removal of all elements including those that System protection is expected to disconnect for each Contingency without operator intervention.
 - R3.2.1.** For all generators, studies shall consider the minimum steady state voltage limitations of all generators and identify how the generators are treated in the steady state simulation.

- R3.2.2.** For all Transmission lines, studies shall consider relay loadability and identify how loadability is treated in the steady state simulation.
- R3.3.** For Steady State studies:
 - R3.3.1.** Performance criteria for System normal conditions and for Planning Events in Table 1 – Steady State Performance shall be met.
 - R3.3.2.** Evaluations shall be performed for single Contingencies (identified in Table 1 – Steady State Performance).
 - R3.3.2.1.** Consequential Load loss (expected maximum demand and expected duration) following a single Contingency shall be identified in the Planning Assessment.
 - R3.3.2.2.** Following single Contingency events, System adjustments other than shedding of firm Load or curtailment of firm transfers are permitted to meet performance requirements provided these adjustments can be accomplished within the time period allowed by the applicable time limited ratings.
 - R3.3.3.** Those Planning Event Contingencies in Table 1 – Steady State Performance not covered in Requirement R3.3.2 that are expected to produce more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe System results.
- R3.4.** Those Extreme Events in Table 1 – Steady State Performance that are expected to produce more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe System results. If the Extreme Events analysis concludes there are Cascading Outages caused by the occurrence of Extreme Events, an evaluation of implementing a change designed to reduce or mitigate the likelihood of such consequences shall be conducted.
- R3.5.** Manual and automatic generation run-back is allowed as a response to single and multiple Contingencies as long as Facility Ratings are not exceeded.
- R3.6.** Manual and automatic generation tripping is allowed for multiple Contingencies and for single Contingencies only in situations that meet all of the following conditions:
 - R3.6.1.** TBD

Note: WECC has informed the SDT that it will be submitting an Interconnection-wide regional variance to allow for manual and automatic generation tripping for single Contingencies. The regional variance will be justified based on physical System differences in the western Interconnection. WECC is developing a white paper to support this position. The actual text of the regional variance will be included in the next posting of this standard.

R4.

For the Stability portion of the Planning Assessment, as described in Requirement R2.4

and Requirement R2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 2 – Stability Performance. The studies shall cover both System Stability and plant Stability. The following requirements apply to both System Stability and plant Stability studies unless otherwise noted. [*Violation Risk Factor: TBD*] [*Time Horizon: TBD*]

- R4.1.** Studies to meet the performance requirements in Table 2 – Stability Performance shall use computer Stability simulations that analyze the response of the BES.
- R4.2.** Contingency analyses shall simulate the removal of all elements including those that System protection is expected to disconnect for each Contingency without operator intervention.
- R4.3.** Studies shall consider the voltage ride through capability of all generators and identify how the generators are treated in the simulation.
- R4.4.** Studies shall identify any planned upgrades (including protection and control modifications) needed to meet the performance requirements of the Planning Events of Table 2 – Stability Performance and validate their effectiveness.
- R4.5.** For the System Stability study:
 - R4.5.1.** At a minimum, those Planning Event Contingencies in Table 2 – Stability Performance that would produce more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information with an explanation of why the remaining Contingencies would produce less severe System results.
 - R4.5.2.** At a minimum, those Extreme Events in Table 2 – Stability Performance that would produce more severe System impacts shall be identified, evaluated for System performance, and the rationale for the Contingencies selected for evaluation shall be available as supporting information and shall include an explanation of why the remaining Contingencies would produce less severe System results. If the Extreme Events analysis concludes there are Cascading Outages, an evaluation of implementing a change designed to reduce or mitigate the likelihood of such consequences shall be conducted.
- R4.6.** For the Plant Stability studies:
 - R4.6.1.** Shall be performed for individual generating units 20 MW or greater directly connected through a step-up transformer to the BES and for generating units at the same location which total 75 MW or greater, directly connected through their step-up transformer(s) to the BES.
 - R4.6.2.** Shall be performed for changes in the real power output of a generating unit by more than 10% of the existing capability or more than 20 MW whichever is greater.
 - R4.6.3.** Shall be performed and evaluated for those Planning Events that would produce more severe System impacts and the rationale for the Contingencies selected for evaluation shall be available as supporting

information and shall include an explanation of why the remaining Contingencies would produce less severe System results. The identified Contingencies, at a minimum, shall be evaluated.

R4.6.4. Shall meet Performance requirements for Planning Events in Table 2 – Stability Performance.

R5. Each Transmission Planner and Planning Coordinator shall determine and identify individual and joint responsibilities for performing the required studies for the Planning Assessment. [*Violation Risk Factor: TBD*] [*Time Horizon: TBD*]

R6. Each Planning Coordinator shall coordinate the distribution of Planning Assessment results among affected entities, coordinating analysis of these results through an open and transparent peer review process. [*Violation Risk Factor: TBD*] [*Time Horizon: TBD*] This distribution shall include:

R6.1. Transmission Planners within the Planning Coordinator's area

R6.2. Transmission Planners of neighboring impacted areas

R6.3. Planning Coordinators of neighboring areas

Table 1 – Steady State Performance

<u>Performance Requirements</u>			
<p>For all Planning Events:</p> <ul style="list-style-type: none"> • Equipment Ratings shall not be exceeded. • System steady state voltages and post-transient voltage deviation shall be within acceptable limits established by the Planning Coordinator (or Transmission Planner if more restrictive.) • Voltage instability, cascading outages, and uncontrolled islanding shall not occur. • Consequential Load loss is allowed for all cases shown. • Simulate the removal of all elements that Protection Systems and controls are expected to disconnect for each Contingency. • Simulate Normal Clearing unless otherwise specified. 			
Planning Events			
#	Event	Interruption of Firm Transfer Allowed (does not result in loss of Load)	Non-Consequential Load Loss Allowed
P1 (single Contingency)	Loss of: <ol style="list-style-type: none"> 1. A generator 2. A Transmission circuit 3. A transformer 4. A shunt device (including FACTS devices) 	No	No
P2 (single Contingency)	Loss of: <ol style="list-style-type: none"> 1. Bus section above 300 kV 2. Non-bus tie breaker (above 300 kV) due to internal fault 3. Single pole of a DC line 	Yes, if transfer is dependent on the outaged DC line No otherwise	No
P3 (multiple Contingency)	Loss of either a generator, Transmission circuit, a transformer with low side voltage rating above 300 kV, or a bus and a stuck non-bus tie breaker (above 300 kV)	Yes, if transfer is dependent on the outaged DC line No otherwise	No
P4 (multiple Contingency)	<ol style="list-style-type: none"> 1. Loss of a generator followed by a System adjustment followed by the loss of a generator. 2. Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line 3. Loss of a generator followed by a System adjustment followed by the loss of a Transmission circuit 4. Loss of a generator followed by a System adjustment followed by the 	Yes, if transfer is dependent on the outaged DC line No otherwise	No

Standard TPL-001-1 — Transmission System Planning Performance Requirements

	loss of a transformer		
P5 (multiple Contingency)	Above 300 kV, the loss of: <ol style="list-style-type: none"> 1. A Transmission circuit followed by a System adjustment followed by the loss of another Transmission circuit 2. A Transmission circuit followed by a System adjustment followed by the loss of a transformer with low side voltage rating above 300 kV 3. A transformer with low side voltage rating above 300 kV followed by a System adjustment followed by the loss of another transformer 	Yes	No
P6 (single Contingency)	Loss of: <ol style="list-style-type: none"> 1. A bus tie breaker due to internal fault 2. A bipolar DC line or an asynchronous tie line 3. A non-bus tie breaker (below 300 kV) due to internal fault 4. A bus section below 300 kV 	Yes	Yes
P7 (multiple Contingency)	Loss of: <ol style="list-style-type: none"> 1. A bus section above 300 kV and a stuck bus tie breaker 2. Either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (below 300 kV) 	Yes	Yes
P8 (multiple Contingency)	Below 300 kV, the loss of: <ol style="list-style-type: none"> 1. A Transmission circuit followed by a System adjustment followed by the loss of another Transmission circuit 2. A Transmission circuit followed by a System adjustment followed by the loss of a transformer 3. A transformer followed by a System adjustment followed by the loss of another transformer 	Yes	Yes
P9 (multiple Contingency)	<ol style="list-style-type: none"> 1. Loss of any two circuits on a common structure (excluding where multiple circuits share a common structure for no more than one mile) 2. Loss of a generator followed by a System adjustment followed by the loss of a monopolar or bipolar DC line, or an asynchronous tie line 3. Loss of a DC line (monopolar or bipolar) or asynchronous tie followed by a System adjustment followed by the loss of a second DC line (monopolar or bipolar) or asynchronous tie 4. Loss of a DC line (monopolar or bipolar) or asynchronous tie followed by a System adjustment followed by the loss of a Transmission circuit 	Yes	Yes

Standard TPL-001-1 — Transmission System Planning Performance Requirements

	<ol style="list-style-type: none"> 5. Loss of a transformer followed by a System adjustment followed by the loss of a DC line (monopolar or bipolar) or asynchronous tie line 6. Loss of a transformer followed by a System adjustment with a spare transformer available followed by the loss of another transformer 		
Extreme Events			
<u>Evaluation Requirements</u>			
<p>For all Extreme Events:</p> <ol style="list-style-type: none"> 1. See Requirement R3.4 2. Simulate the removal of all elements that Protection Systems and controls are expected to disconnect for each Contingency. 3. Simulate Normal Clearing unless otherwise specified. 			
Extreme Event Descriptions			
<ol style="list-style-type: none"> 1. Loss of a single generator, Transmission circuit, DC line, or transformer forced out of service followed by another single generator, Transmission circuit, DC line, or transformer forced out of service prior to System adjustments. 2. Local area events affecting the Transmission System such as: <ol style="list-style-type: none"> a. Loss of tower line with three or more circuits b. Loss of all Transmission lines on a common right-of-way c. Loss of switching station or substation (loss of one voltage level plus transformers) d. Loss of all generating units at a station e. Loss of a large Load or major Load center 3. Wide area events affecting the Transmission System such as: <ol style="list-style-type: none"> a. Loss of a large gas pipeline into a region or multiple regions that have significant gas-fired generation b. A successful cyber attack c. Regulation that restricts or eliminates the use of a river or lake or other body of water as the cooling source for generation d. Shutdown of a nuclear power plant(s) and other facilities a day or more prior to a hurricane, tornado or wildfire, or for other common causes e. Regulation that restricts or eliminates the use of a river or lake or other body of water as the cooling source for generation f. Shutdown of a nuclear power plant(s) and other facilities a day or more prior to a hurricane, tornado or wildfire, or for other common causes such as problems with similarly designed plants g. The loss of older Transmission lines which may not be constructed to meet an entity's present radial ice or wind loading requirements, while the newer or stronger Transmission lines remain in service h. Other events based upon operating experience 			

Table 2 – Stability Performance Table

<u>Performance Requirements</u>			
For all Planning Events:			
<ul style="list-style-type: none"> • The System shall be stable¹ • Dynamic voltages shall be within acceptable limits established by the Planning Coordinator or Transmission Planner (if more restrictive) • Uncontrolled islanding and Cascading Outages shall not occur • Simulate the removal of all elements that Protection Systems and controls are expected to disconnect for each Contingency. • Simulate Normal Clearing unless otherwise specified. 			
Planning Events			
#	Initial Condition	Event	Non-Consequential Load Loss Allowed
P1 (single Contingency)	System normal	Single Line Ground (SLG) fault on, a 3-Phase (3Ø) fault on, or an unexpected loss without a fault of (whichever is worst): 1. A generator 2. A Transmission circuit 3. A transformer	No
P2 (single Contingency)	System normal	1. SLG fault on bus section above 300 kV 2. SLG internal fault in non-bus tie breaker (above 300 kV) 3. A single pole block of a DC line	No
P3 (multiple Contingency)	System normal	SLG fault on either a generator, Transmission circuit, a transformer, or a bus and a stuck ² non-bus tie breaker (above 300 kV)	No
P4 (multiple Contingency)	A single generator out of service followed by System adjustments	1. Apply a P1.1 Contingency. 2. Apply a P2.3 Contingency. 3. Apply a P1.2 Contingency. 4. Apply a P1.3 Contingency.	No
P5 (multiple Contingency)	A Transmission circuit above 300 kV out of service followed by System adjustments	1. Apply a P1.2 Contingency. 2. Apply a P1.3 Contingency.	No

Standard TPL-001-1 — Transmission System Planning Performance Requirements

	A transformer with low side voltage rating above 300 kV out of service followed by System adjustments	3. Apply a P1.3 Contingency.	
P6 (single Contingency)	System normal	1. SLG internal fault in bus tie breaker 2. A bipolar block of a DC line 3. SLG internal fault in non-bus tie breaker (below 300 kV) 4. SLG fault on bus section (below 300 kV)	Yes
P7 (multiple Contingency)	System normal	1. SLG fault on a bus section above 300 kV and a stuck bus tie breaker 2. SLG fault on either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (below 300 kV)	Yes
P8 (multiple Contingency)	A Transmission circuit below 300 kV out of service followed by System adjustments A transformer with low side voltage rating below 300 kV out of service followed by System adjustments	1. Apply a P1.2 Contingency. 2. Apply a P1.3 Contingency. 3. Apply a P1.3 Contingency.	Yes
P9 (multiple Contingency)	System normal A single generator out of service followed by System adjustments A DC circuit out of service followed by	1. SLG fault on each circuit of any two circuits on a common structure (excluding events where multiple circuits share a common structure for no more than one mile). 2. Apply a P6.2 Contingency. 3. Apply a P2.3 Contingency. 4. Apply a P1.2 Contingency.	Yes

	<p>System adjustments</p> <p>A transformer out of service followed by System adjustments</p> <p>A spare transformer inserted to replace an outaged transformer followed by System adjustments</p>	<p>5. Apply a P2.3 Contingency.</p> <p>6. Apply a P1.3 Contingency.</p>	
Extreme Events			
<p><u>Evaluation Requirements</u></p> <p>For all Extreme Events:</p> <ul style="list-style-type: none"> • See Requirement R4.5.2 in the text • Simulate the removal of all elements that Protection Systems and controls are expected to disconnect for each Contingency. • Simulate Normal Clearing unless otherwise specified. 			
<ol style="list-style-type: none"> 1. 3Ø fault on generator with stuck breaker 2. 3Ø fault on Transmission circuit with stuck breaker 3. 3Ø fault on transformer with stuck breaker 4. 3Ø fault on bus section with stuck breaker 5. 3Ø internal fault in breaker 6. 3Ø fault on two or more circuits on a common structure 7. SLG or 3Ø fault on all Transmission lines on a common right-of-way 8. 3Ø fault on switching station or substation (loss of one voltage level plus transformers) 9. 3Ø fault with loss of all generating units at a station 			

Notes:

1. System stable means:
 - a. Angular stability:
 - i. For Planning Events P1 and P3.2: No generating unit or units shall be allowed to pull out of synchronism. A generator being disconnected from the system by fault clearing action or by a Special Protection Scheme is not considered pulling out of synchronism.
 - ii. For all other Planning Events: No generating unit or units totaling more than the contingency reserve (spinning reserve) of the Balancing Authority shall be allowed to pull out of synchronism. Generators that pull out of synchronism must have out-of-step protection and the resulting apparent impedance swings must not pass through relay characteristics that would result in the tripping of

- any transmission system elements other than the generating unit and its direct connection facilities.
- iii. For all Planning Events: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator or Transmission Planner (if more restrictive).
 - b. General: Unplanned islanding of portions of the system shall not occur for Planning Events.
2. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) breaker, only one pole is assumed to remain closed.

C. Measures

M1. To be supplied at a later date.

E. Regional Variances

1. WECC Interconnection-wide waiver is under development (see Requirement R3.6.2).

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment:</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment:</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q6. Comment:</p>	
<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment:	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q9. Comment:	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment:	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment:

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment:

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment:

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment:

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment:

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment:

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment:

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment:

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Yes No
 Comment:

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No
 Comment:

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No
 Comment:

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment:

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment:

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment:

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment:

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment:

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment:

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment:

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment:

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment:

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment:

September 12, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Comment Period Opens

The Standards Committee (SC) announces the following standards actions:

First Draft of TPL-001-1 — Transmission System Planning Performance Requirements Posted for 45-day Comment Period

The first draft of [TPL-001-1](#) — Transmission System Planning Performance Requirements is posted for a 45-day comment period from September 12 through October 26, 2007. The purpose of the proposed standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

The proposed standard consolidates, clarifies, and expands on the requirements that had been in TPL-001-0, TPL-002-0, TPL-003-0 and TPL-004-0, and includes several new definitions.

Note that the drafting team will hold a WebEx and Conference Call on Wednesday, October 10 from 1 p.m. to 4 p.m. EDT to present and discuss the proposed requirements in TPL-001-1. The purpose of this call is to provide stakeholders with an overview of the proposed requirements, to highlight the areas where the proposed requirements differ from the requirements in the existing TPL-001-0 through TPL-004-0, and to provide stakeholders with the opportunity to ask questions about the proposed requirements.

Please use this [comment form](#) to provide comments on the first draft of this standard.

Standards Development Process

The [Reliability Standards Development Procedure](#) contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment: Agree but delete "or node". It is unnecessary.</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
<p>Q2. Comment: See Q6. Also, from your definition above, a better term would be "directly-connected load loss". This is clear and to the point.</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
<p>Q6. Comment: Most people will think of inconsequential, which often means irrelevant, unimportant, or insignificant. But what you are trying to define is the opposite: load loss that is significant, important, and needs to be</p>	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

prevented. Also, whatever you call it, your examples (UVLS, UFLS, SPS) should be expanded to include unintentional and uncontrolled load loss due to low voltage, high current, impedance relays, etc.	
Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment: Agree but adjust language. You are saying "require requirements to be met". Duh. Even if you took out one of them and said "requirements must be met", this is also redundant. The definition of "requirement" is that it is required. How about "Events for which there are strict transmission performance standards that must be met." This may also be slightly redundant, but not as much as the original.	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q9. Comment: I don't see any reason to differentiate between "Plant Stability" and "System Stability". These are not commonly separated. A better differentiation would be between generator (or angular) stability and load (or voltage) stability. These are usually independently studied and indendently occurring.	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q10. Comment: See Q9.	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment: Agree but delete "annual". Unnecessarily restrictive. Aren't there non-annual studies for which the definition of "year one" is important?	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.
- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment: No. However, as long as we're talking about it, NERC should set a standard for the definition of the "peak load" to be planned for. Some utilities use the 50% probability peak load. Some use 90%. A big difference that will result in a big difference in how they are prepared for the peak load days. The sensitivity section is not sufficient to address this.

Also, outages of reactive resources should be (and are) in the list of contingencies, not sensitivities.

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment:

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment: Absolutely.

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment: First of all, you are not exactly requiring that DSM be considered or analyzed. You have simply listed it as one of the possible solutions. And you should mention the possibility of "integrated plan" in the standard itself. Since DSM is simply optional, let the planners figure out themselves how to consider DSM.

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment: Any area where there might possibly be an impact. I.e., engineering judgement.

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment: Yes, it helps when considering other issues in the same area. You would know whether or not you can count on a project going in.

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment: It's kind of obvious. If you require a solution to begin with, then if that solution is removed, another solution must be planned. However, if the removed project

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

is not directly related to the study or problem at hand, then engineering judgement will be needed as to whether or not to repeat the study.

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to “raise the bar.” Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	Loss of load is not usually considered by transmission planners. In power flow studies, they look at flows and voltages versus limits. In stability studies, they are looking for angles, speeds, and voltages that stabilize at good values, possibly with temporary excursions less than some limits. How should all these be converted to a loss of load value? Normally we ensure no loss of load <because> we meet thermal, voltage, and stability requirements. Maybe you are saying that planners should not use load tripping as a solution for these violations?
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

followed by System adjustment ¹ followed by loss of another Transmission circuit	agree.	
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment: When talking about breaker outages, I see no reason to differentiate between "non-bus tie" and "bus tie" breakers. Are bus tie breakers inherently more reliable? If the effect on the system due to a tie breaker outage is very bad, then this should be fixed. All other contingencies seem to be slotted based on probability. Shouldn't breakers? Maybe bus tie breakers are weak points in the transmission system that need to be improved.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No

Comment: Table 1 P3 is a little hard to read/understand. The second column should start out something like "A stuck breaker following the outage of any 1 of the following:" However, P3 will be completely redundant with P2 because, in power flow analysis, there is no difference between a breaker internal fault and a stuck breaker following an external fault. The final outaged equipment is the same. This will cause extra unnecessary work.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	For Table 1 P4, rewrite it to read "Loss of a generator followed by a System adjustment followed by the loss of any one of the following: 1. Generator 2. Transmission Circuit 3. Transformer 4. A shunt device 5. Single pole of DC line." This structure is easier to read and understand. The order should be like this to match P1. Shunt devices should be included. P3 should be structured similarly.
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No

Comment: Yes, this is the purpose of HVDC. It carries the power your want, no more, no less. Both the good and bad of parallel flows are avoided.

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No

Comment: Yes, I like this. You can maintain them to be as similar as possible, while still containing the requisite differences.

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment: I don't see any reason to differentiate between "Plant Stability" and "System Stability". These are not commonly separated, and this distinction is not standard in the industry. You should not be inventing a distinction that doesn't exist. A better differentiation would be between generator (or angular) stability and load (or voltage) stability. These are usually independently studied and independently occurring.

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment: No. Good idea. A whole plant may be out because of a shortage of cooling water, but this is an orderly shutdown, not a sudden event. It is only appropriate for steady-state.

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment: Yes, but the impact on the models and studies is unknown. Some testing needs to be done with full Eastern and Western Interconnection models to see how they handle motor models at every load. I've performed numerous studies where loads in an entire utility or state have been converted to a large % of motors, and the effect can be shocking. The programs (PSS/E and PSLF) may completely bog down if this is done for a whole interconnection. Many stability problems will be found. We definitely need to transition to this, but with care.

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Comment: For multiple, only automatic schemes. For single, only automatic schemes if the loss of MW is shown to be acceptable.

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment: Every single event will eventually require preparing for the next event. But we cannot plan for every next event. Only specific single and multiple contingencies should be planned for, all flows must be within an established rating of some kind (continuous, 12-hour, 4-hour, 15-min, whatever), and the idea of the "next event" should not be included in a planning standard.

Now maybe there should be a limit as to how short the time of a rating can be in Planning. For example, planning to a 15-min rating is a bad idea. That rating can be used by operators in emergencies, but planners need to do something better. A minimum should be set (e.g. 1 hour rating). I guess if a company wants to use a 15-min rating and then AUTOMATICALLY transition to a 1-hour or 12-hour rating with runback or something else, that is reasonable.

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment: No. Following a single contingency, all flows must be within some kind of established rating. After that, runback can be used to get under a longer-term rating.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

For multiple contingencies, some type of cross-tripping is OK, but runback is too slow and unreliable.

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment: It makes the system too complex and less reliable. Single contingencies need to be handled without any fancy controls.

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment: They could be used in the short term until a permanent fix is available. Limit to <5 years.

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment:

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment:

Q43. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Yes No

Comment: In Table 2 P3, more clarification is needed for "above 300 kV". For generators, does that mean those whose POI is >300kV? For transformers, is it the secondary voltage? Also, is the footnote referencing correct?

"A transformer with low side rating above 300 kV" is confusing for transformers with 3 windings. What's the low-side rating of a 500/345/13.8 kV transformer? You should say "a secondary voltage rating above 300 kV" and define "secondary voltage rating" as the second highest voltage rating. This is standard nomenclature. Also, I assume you know that there aren't very many of these. The possibilities are 765/500, 500/345, and 765/345. The first two are uncommon, and the 3rd is only common in AEP and HQ.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

In P3, does the 300 kV limit apply to the transmission circuits as well? It is hard to tell.

In R1, you say "Each ... shall each ..." Delete the second "each", which is redundant. Also delete "required for system performance studies". These words are not part of the requirement. They are part of the justification for the requirement.

Table 1, Extreme Event Descriptions, 3d and 3f are almost identical.

Table 1, P9-1, rewrite as "... (excluding circuits that share common structures for one mile or less)". P9-1 uses "structure" whereas Extreme 2a uses "tower". Make consistent.

P9-2 monopolar is already covered under P4-2.

For all of the multiple contingencies with System Adjustment in the middle, group them together something like this (for those with the same requirements):

"Outage of any one of the following:

- 1.
- 2.
- 3.
- 4.

followed by System Adjustments followed by outage of any one of the following:

- a.
- b.
- c.
- d."

This is easier to understand than separately writing each possible combination of 2.

Overall, the structures of the Tables needs to be made clearer and more consistent. But the ideas are good.

The transition is going to be critical for some of the standards that may require significantly more study work and significant capital investments in transmission infrastructure.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment:</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment:</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment: However this could be very subjective.</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q6. Comment:</p>	
<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment:	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q9. Comment:	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment:	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment:

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment:

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment: We believe that only the worst case would need to be addressed for stability purposes.

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment:

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Comment:

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment:

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment: However, the question as to what is considered committed versus proposed. There are various steps in the approval process for our company and we are not sure which approval would be considered committed.

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment:

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment:

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No
 Comment:

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No
 Comment:

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Yes No

Comment:

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment:

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment: Agree with the statement above as to the timefram regarding stability.

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment: However, getting all the modleing data is not easy and may take some time.

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment: Whatever the generator is capable of.

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment:

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment: We do not have the capability to have automatic runback at this time. However if an entity does have the capability to perform automatic runback than it should be allowed to prevent overloads. That would be the purpose.

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment:

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment: no comment

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment: no comment

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment:

Q43. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Yes No

Comment: Based on the p1 to P9 events one would have to model a breaker to breaker instead of bus to bus. This would be a large undertaking and it seems that it would be more conservative to have a bus to bus model.

Question on P4 - does this apply to all generators on a system or is there a MW limit to the size of the generator.

P5 Does this mean running N-2 for the 300 KV for all seven cases that would be required. This could take a large amount of computer run time.

We are stating that this change to the standard is not warranted. However, if all these changes are implemented what used to take approximately 1 month to assess will now take approximately 4 months and we are not that big of a system. I assume that the time and manpower to perform all the contingencies has been considered.

**Comment Form for First Draft of TPL-001-1 — Transmission System
 Planning Performance Requirements**

Please use this form to submit comments on the proposed draft of TPL-001-1. Comments must be submitted by **Friday, October 26, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "TPL-001 Draft 1" in the subject line. If you have questions please contact Ed Dobrowolski at ed.dobrowolski@nerc.net or by telephone at 609-947-3673.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment: Due to the length of this questionnaire and the different regional approaches to how IRC members meet the TPL requirements, individual ISO RTOs have chosen to respond separately. Collectively the IRC SRC provides comments in #43 of this questionnaire.</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment:</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q6. Comment:</p>	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q7. Comment:</p>	
<p>Q8. Planning Events: Events which require Transmission system performance requirements to be met.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q8. Comment:</p>	
<p>Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q9. Comment:</p>	
<p>Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q10. Comment:</p>	
<p>Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q11. Comment:</p>	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.
- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment:

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment:

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment:

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment:

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment:

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment:

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment:

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment:

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment:

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment:

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment:

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment:

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment:

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment:</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment:</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q6. Comment:</p>	
<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment:	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q9. Comment:	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment:	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment:

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment:

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment:

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment:

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment: NERC is revising the Transmission Planning Standards beginning with TPL-001. Alcoa agrees with NERC's approach to revising TPL-001 wherein NERC is consolidating duplicative Standards to promote consistent requirements of the planning process and thus improving reliability. Also, Alcoa agrees that new studies should not result in inadvertent negative impacts on the system especially when such studies have not taken into account the negative impact on an adjacent system.

However, Alcoa believes that the current draft of the TPL fails to address FERC Order 890's requirements of an open and transparent Planning Process. Such a process provides Market Participants an equal opportunity for consideration in the Planning Assessments for contingency impact on transmission availability. (See FERC Order 890 ¶¶ 140, 207, 212, 323, 327, 337). Alcoa also believes that the current draft of the TPL fails to address and incorporate FERC Order 890's new requirement that transmission providers coordinate "...ATC calculations with their neighboring systems."

For example, while Planning Assessments may indicate no NERC Compliance violations where the Table 1 and Table 2 Requirements are met, Market Participants are harmed and not provided protection from unequal treatment of their circumstance. This problem occurs when an analysis of a contingency event results in no IROL or SOL (all facilities remain within established ratings), but resultant transmission constraints cause reductions of ATC and subsequent market impact. As part of the System Planning Process, this is unacceptable, and, as a minimum, this type of situation must be included as a scenario reviewed in the required sensitivity analysis under the NERC TPL-001-1 Standard.

The impact of such practices by large transmission providers on the ATC of smaller transmission providers can be significant. For instance, small transmission providers similar to Alcoa that operate non base-load resources such as hydropower, peaking units or wind power can easily see their ATC's reduced when sensitivity analyses are not performed under TPL-001-1. Alcoa believes that such sensitivity analyses should be a requirement.

Alcoa believes that for consistency with the provisions of Order 890, NERC must re-visit not only the Planning Assessment implications on transmission availability but also couple this review with the revision of the NERC Modeling Data and Assessment Standards (MOD). Alcoa recommends that the MOD and TPL Standards be addressed in similar fashion to:

- 1) Incorporate the intent of Order 890 requirements of an "Open and transparent Regional Planning Process to provide non-discriminatory planning" for ALL Market Participants
- 2) Assure that the revised MOD and TPL Standards fully address implications of burdens on the Bulk Electric System (BES) related to transmission availability for contingencies in the Planning Process.

FERC Order 890 ¶ 523 - Coordinate planning with interconnected systems. In addition to preparing a system plan for its own control area on an open and nondiscriminatory basis, each Transmission Provider will be required to coordinate with interconnected systems to (1) share system plans to ensure that they are simultaneously feasible and otherwise use consistent assumptions and data and (2) identify system enhancements that could relieve congestion or integrate new resources. (Emphasis added).

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

3) Sensitivity Analysis should include the potential impact on transmission availability and/or reductions in ATC on adjacent systems. Where ATC on an interface is reduced for a single contingency (N-1 planning, mitigation options must be provided). (This may require a threshold level of ATC reduction where a percentage reduction would be specified as acceptable on the N-1 basis, and a greater reduction than that threshold would be considered a Standard's Violation).

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment:

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment:

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for	<input type="checkbox"/> Agree.	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

stability) above 300 kV	<input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment:

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No

Comment:

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No
 Comment:

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No
 Comment:

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No
 Comment:

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment:

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment:

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment:

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment:

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment:

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment:

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment:

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment:</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment:</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q6. Comment:</p>	
<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment:	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q9. Comment:	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment:	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment: Scenario analysis should be based on the unique aspect of the particular Transmission zone. Transmission Planners should work to select the best scenarios related to the specific system and adequately describe the selection process..

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment: Providing examples would be helpful but specifically stating the required thresholds are transmission system dependent. Providing some methodologies to follow may be prudent such as forecast levels like 90/10; 80/20; or 50/50.

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment:

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment: No sensitivity needed for long term assessment.

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment: It should be included if there are specific mandated or approved DSM programs in place during the study period.

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment: Study area should be at least two buses beyond deficiency and plan elements.

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment: There needs to be a clear definition developed for committed and proposed projects and those definitions need to be included in the definition section of the standard.

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment:

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment:

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No

Comment:

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No

Comment:

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No

Comment:

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment:

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment:

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment:

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment: Should not be limited

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment:

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment: This could be permitted provided the run back will allow for the ability to prepare for the next operational contingency and not affect load.

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment:

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment: The use of these system should be limited and not used as a preferred solution and also be approved by a stringent review process through the RTO & RE.

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment: The system should remain stable, reliable, allow for operational preparation for the next contingency and failure of the RAS/SPS should not lead to a cascading event.

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment:

Q43. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Yes No

Comment: General Comments:

1). We believe the 300kV cutoff should not be used. It should be based on the definition of a Backbone Facility. The 300kV and above standards should only apply to backbone facilities that are used to provide overall energy transfer and ties to other systems and not facilities that provide load serving purposes. Backbone facilities should be specifically defined and accepted as Backbone facilities through RTO and RE review and acceptance.

2). Planning Scenarios should be forced to include a market based scenario under the Planning Authority obligation which should include long range market projections for generation dispatch, significant energy price changes due to environmental issues or fuels, and market impact of large transmission reinforcements.

3). It should be noted in the process that additional planning resource additions (maybe as much as 30%) will be required to meet these new study requirements since they are much more expansive than the existing requirements.

4). These standards could require substantial (millions) upgrades to the system to meet the proposed changes. These are primarily due to the 300kV and above standard revisions and the non-consequential load drop criteria adjustments.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment: Yes, we agree that the "base case" is a power flow model and is the starting point of the analysis. What we are concerned with are the assumptions that go into the development of the "base case". The season, time of day, load level, generation dispatch assumptions, facilities in service, and interchange assumptions (all based on best available data) are just a small subset of the issues that need to be addressed in the development of the base case. We have concerns that so-called "stressed cases" proposed in the standard for compliance testing may in reality be contingency cases, from which additional compliance performance testing would be required.</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment: A better name for this would be "direct load loss". The definition should include load served by the faulted element but not directly connected to the faulted element.</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
<p>Q3. Comment: Most planning events have a low probability of occurrence. It appears that the SDT is trying to make a distinction that these extreme events would have a lower probability of occurrence than planning events. Consideration should be given to adding the performance requirements with the definition.</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q4. Comment:	
Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q5. Comment: It is suggested that another definition be added for "operations planning horizon".	
Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q6. Comment: A better name for this would be "indirect load loss".	
Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q7. Comment: We do not agree that the planning assessment should include asset conditions and age. The age of equipment, if it is well maintained, has little impact on reliability. If NERC wants a standard to deal with age and maintenance of equipment, then it should develop a separate standard for asset management and not overburden TPL-001-1 with such issues.	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q8. Comment: Consideration should be given to adding the performance requirements in the definition.	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q9. Comment: It seems that the SDT is trying to divide the stability issues between plant (local) and system. As the system load representation and its damping characteristics affect both plant and system stability, it is difficult to separate plant versus system stability studies. The focus of the studies may be only slightly different, depending on the location, type, and duration of the fault conditions assumed.	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q10. Comment: See comments above in the response to Q9. Specific inclusion of voltage (load) stability seems to be missing from the definition. Also, angular stability is mentioned only as part of the definition for System Stability Study and not Plant Stability Study. It would seem that this item would be part of both types of study.	
Q11. Year One: The first year that a Transmission Planner is	<input checked="" type="checkbox"/> Agree.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.
- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment: For the purposes of compliance, we believe that the existing requirement R1 in Standard TPL-001-0 adequately defines the sensitivities that need to be covered in a valid assessment, and no additional clarification is necessary. Deterministic tests of a limited number of system conditions require the application of engineering judgement to evaluate the complex multi-variable problems involved in planning analyses. We all agree that performing contingency analyses on a single snapshot of expected system conditions is not adequate to plan the transmission system, but planning is not a cookbook exercise, and neither is an engineering assessment of planning activities demonstrating required system performance. Further, we believe that a test of incremental transfer capability determined from some of the sensitivity cases needs to be added to the standard and would go a long way to address how much margin exists in the transmission system to handle the unknown or previously undefined variables.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment: There is no need to build a multitude of sensitivity cases to assess the reliability of the system. The sensitivity issues should be handled on an individual system basis by the local transmission planners as applicable to the study system. Conditions that are considered as "stressed" for one area may require all facilities to be in service in another area. Powerflow cases utilizing a number of the items listed under R2.1.3 or R2.4.3 could be produced for in-house study work, but such work should not be required as part of standards compliance. The standard should not be dictating what types of sensitivities should be investigated or considered for all parts of the transmission system.

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment: The biggest problem with performing stability analysis is getting the stability cases to match up with the powerflow cases, and only a limited number of stability cases are developed each year. Further, for those systems that are planned in excess of the NERC Standards regarding stability (3-L-G or 2-L-G vs. 1-L-G as in the Standard), there are no benefits to performing additional sensitivity studies to demonstrate compliance with this standard.

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment: There are more unknowns in the longer-term studies than in the near-term studies, which would indicate that more sensitivity studies would need to be performed and not less. However, it is more reasonable to suggest that if near-term sensitivity studies show a problem in a particular part of the system, then similar sensitivity studies need to be performed in the longer-term analyses.

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment: If DSM can be implemented in the required operating time, we have no objections to using DSM as the planned mitigation to relieve overloads or low system voltages for multiple contingency conditions, but not as a long-term solution for single contingency conditions. However, from our experience, we believe that developing enough DSM in the required time at specific locations in the system will be difficult, and that plain load-shedding would be required to supplement the DSM to achieve the desired performance.

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment: This proposed requirement is unnecessary and a waste of time. Keep in mind this is a planning assessment and not a facilities study. Further, such a requirement implies a distrust of the transmission planners to develop valid corrective action plans to meet the requirements of the TPL standard.

For more complex system facility additions, it would be inconceivable that a Transmission Planner or Owner or Planning Coordinator would proceed without performing powerflow simulations to determine the efficacy of the system addition. But these studies would be performed over time considering the best available information and latest standards performance requirements.

The majority of transmission projects consist of the upgrading of terminal equipment or conductor on one or more branches. The only significant change that such upgrade work would produce in a powerflow model would be that the branch ratings would change. It is not necessary to rerun powerflow simulations for such cases, as it can be determined by inspection whether the upgrade work would be sufficient to move the facility rating above the expected normal or contingency flow.

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment: We understand that there are differences between committed and proposed projects in an RTO environment where there is cost sharing for facility upgrades. From a NERC Standards compliance perspective, however, we do not see a need to differentiate between proposed and committed projects in the corrective action plan, as

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

long as either properly addresses the required performance issue. We are not sure why there is a need to develop or maintain information on committed projects. This tracking is not needed to meet the existing TPL standards. Compliance requirements should be kept separate from administrative data requests. What is the perceived need to track committed projects that has not been presented here? Is this another example of distrust for transmission owners to build the proper facilities to create a more robust system?

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment: As stated above, we are not sure why there is a need to develop or maintain information on committed projects. This tracking is not required in the existing TPL standards. As long as the revised corrective action plan meets the reliability performance requirements, what difference does it make if a committed project is cancelled or changed to a proposed project from a compliance perspective? We need to keep compliance requirements separate from administrative data requests or survey responses.

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus	<input checked="" type="checkbox"/> Agree.	No significant material change identified.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

section (SLG for stability) above 300 kV	<input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.	Load pockets supplied by a single EHV substation with only two supplies would not meet this proposed requirement, whereas the existing TPL-003-0 standard would allow the dropping of load for the multiple outage event. A significant material change to build new facilities would be needed to meet the new requirement.
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	No opinion as we do not have any transformers with the low side voltages rated above 300 kV. Transmission owners with transformers meeting this requirement should be consulted to determine if a material change would be required.
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	No opinion as we do not have any transformers with the low side voltages rated above 300 kV. Transmission owners with transformers meeting this requirement should be consulted to determine if a material change would be required.

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment: This part of the proposed standard language is confusing. From our perspective, the failure of any 300 kV or above non-bus-tie circuit breaker should not result in the non-consequential loss of load. Further, EHV circuit breakers failing as a result of internal faults are extremely rare, bus-ties or not. Also, it is not clear what would be considered a non-bus tie breaker for ring bus and breaker-and-a-half bus configurations. It would seem that performance requirements for EHV bus-tie breakers (and not non-bus-tie breakers) should be distinguished from other breakers.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No

Comment: The loss of two or more elements at any EHV substation at time of peak would likely result in loss of non-consequential load. If the intent of the proposed standard is to encourage the development of ring bus or breaker-and-a-half bus arrangements at the EHV level, we would concur where it is physically possible and makes for good engineering practice. However, we must remind the SDT that there are some existing facilities that cannot be converted practically or economically from their present straight bus configuration because of physical limitations. A significant material change, potentially several million dollars per substation, would be required to retrofit facilities, where possible. It would appear that performance requirements for EHV bus-tie breakers (and not non-bus-tie breakers) should be distinguished from other breakers.

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	The outage of any two generators should not result in any non-consequential loss of load.
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	The outage of a generator and any other element should not result in any non-consequential loss of load.
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	The outage of a generator and any other element should not result in any non-consequential loss of load.
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	The outage of a generator and any other element should not result in any non-consequential loss of load.

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Comment: If the system cannot withstand the outage of the single element (AC or DC) without curtailment of the transfer, then the transaction should not be considered as firm.

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No

Comment: We understand the need to clarify the different requirements in the steady-state vs. the stability analyses. However, for each contingency category we expect to see both the steady-state requirements and the corresponding stability requirements in the same table. We believe that it would be better to recombine the steady-state and stability tables and present the information in a landscape format.

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment: We appreciate the SDT concern for performing repeated plant stability studies without any change in plant/machine characteristics. However, as the system load representation and its damping characteristics affect both plant and system stability, it is difficult to separate plant versus system stability studies. On some systems in which load and generation are tightly coupled, the focus of plant or system stability studies may differ only slightly with the location and duration of applied fault events. As such, the scope and manner of conducting System Stability study work under Requirement R2.4. for such portions of the interconnected system is not clear. Differences between Plant Stability Studies and System Stability Studies need to be made more clear.

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment: A good test of the robustness of the interconnected system is its ability to handle import plus heavy inrush conditions, such as might occur with loss of a large plant. While the probability of such random events would be very low, the possibility still exists that intentional sabotage could result in such an event.

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment: Dynamic studies of peak load conditions should include the effects of induction motors, and particularly in areas where traditional load models have indicated a problem. Unfortunately, there is a lack of data to support the amount and characteristics of the detailed induction load models in many areas. In addition to the consideration of the dynamic effects of induction motor loads, the effects of static capacitor banks installed at both distribution and transmission voltage levels would need to be considered as well. The industry would be looking to NERC for some guidance as to how this data should be developed and maintained for models in future years.

Note that meeting such a requirement would necessitate a significant increase in the dynamic data needed to represent the system. Also, maintenance of such load model data would need to be considered. Load characteristics valid for a near term model might not be valid for future years. Also, summer peak load, winter peak load, and off-peak load characteristics would differ.

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment: No adjustment of firm (network resource) generation should be allowed for the long-term mitigation of a single contingency. Allowing post-contingency shifts of firm generation as a long-term mitigation of a single contingency event is short-sighted and would not produce a robust system that is required to handle more than single contingency events. Redispatch of firm generation may be required in the near-term as an interim operating guide or procedure until the limiting transmission element can be uprated or other system reinforcement is in place. Generation redispatch should also be allowed to prepare for the next single contingency. For responding to multiple contingencies, redispatch of firm generation should be allowed in the mitigation plan provided that the redispatch can be accomplished in the required operating time and the contingency overloads are not overly severe (indicating possible cascading). Firm generation should also be tripped to quickly mitigate contingencies involving multiple generation outlet transmission circuits. Non-firm (energy only) generation can be tripped or redispatched for any contingency event as needed to keep facility loadings within ratings.

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment: The runback of firm generation should only be allowed as a valid interim operating procedure until a system reinforcement would be installed to uprate or unload the limiting facility. The use of the runback scheme should not be allowed as the long-term solution to a single contingency event. As mentioned above in the response to Q35, non-firm (energy only) generation should be tripped or redispatched for any contingency event as needed to keep facility loadings within ratings.

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment: No generation runbacks should be allowed as long-term solutions for single contingency conditions.

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment: Yes, but only as interim operating procedures until the limiting facilities can be uprated or unloaded. SPS or RAS should be allowed to trip non-firm (energy only) generation to keep facility loadings within ratings.

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment: SPS and RAS should be used only as interim operating procedures to mitigate single contingency events until the limiting facilities can be uprated or unloaded. SPS and RAS should be allowed to trip non-firm (energy only) generation as needed to keep facility loadings within ratings.

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Comment: RAS and SPS should be allowed only as an interim operating procedure to mitigate single contingency conditions or to mitigate multiple contingency events on a long-term basis. The RAS or SPS must be effective in mitigating the contingencies and can be implemented within the required operating time.

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment: The proposed standard, as well as the existing standards, makes no distinction between firm (network resource) and non-firm (energy only) generation. The standard should clearly state that the standard does not apply to non-firm generation.

Q43. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Yes No

Comment: Much of the language under R1 appears to be redundant with model data requirements as listed in Reliability Standard MOD-010 and MOD-011. Such information would typically be used to produce an annual series of powerflow cases. Instead of supplying such information in a piecemeal manner to the Planning Coordinator as a separate annual effort, the Planning Coordinator should make use of the most recent set of powerflow models. This requirement, as written, could cause a needless duplication of work effort.

It is not clear what is meant by 'stressed System conditions' in Requirement R1.2. Does this mean higher than predicted load, lower than expected reactive resources, or other meaning? It is also not clear what is covered by 'load models' in the same requirement.

It is not clear how expected transfers are to be modified in Requirement R2.1.3.2. Possibilities include higher or lower in the same transfer direction, turn transfer directions around so that importers become exporters, the inclusion of non-firm transfers that can be cut, or change import/export directions. There should be some basis for the sensitivity change.

It is not clear how planned transmission outages are to be modified in Requirement R2.1.3.7. Possibilities include modification of the outage duration, or modifications involving more or less facilities. Since outages are scheduled in the operations planning horizon, based on the best information available at the time of the outage request, it is questionable whether they should not be included in standards that apply to planning in years 1-5 or year 6-10 and beyond.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Requirement R2.2.1. should be deleted. Uncertainties involved with studies looking at system conditions out to ten years in the future would preclude the need to extend a Planning Assessment beyond the ten year period. Any corrective actions needed to resolve problems found during study of long-term system conditions could be noted in the Planning Assessment without the need to extend beyond ten years.

In Requirement R2.3, the scope of the study work involving the short circuit portion of the Planning Assessment is not clear. It is not clear whether the study work should be based on three-phase faults only, three-phase and single-phase faults, or whether classical representation or more a more detailed representation should be utilized.

We assume that Requirement R2.4.3.5 would require only known generation additions, retirements, or other dispatch scenarios, and that those performing the planning scenarios would not speculate on unknown generation additions and retirements.

A market structure change in Requirement R2.6.1 would not constitute a material change in an area with an abundance of low cost base load generation that was always on before the market change and would still be on after the market change.

Under Requirement R2.6.3., Plant and System Stability analyses are considered valid until material changes in the System invalidate previous study work. Here, material changes in the system include addition of a transmission line or generator. Addition of a transmission line or generator would only have an impact on stability of generators near the new facility installation. This is not clear from the wording of the standard, which would appear to require restudy of all generators if a transmission line or generator is added anywhere on the system.

What would be the duration of interim operating procedures in Requirement R2.7?

Requirement R.2.7.1.1. states that a project initiation date should be included in the Corrective Action Plan for each project, as well as an in-service date. A project initiation date may be of use to the particular project design engineering staff, but is of little use in planning the system. Keep in mind that this is a Planning Assessment and not a data request.

The wording of Requirements R3.2 and R4.2 appear to require taking all transmission elements as contingencies, plus modeling contingencies which would remove all elements automatically via System protection equipment. Based on comments from the SDT, the inclusion of all single elements in the set of contingencies to be considered is not intended as part of these requirements. Please verify this in writing.

The wording of Requirement R3.2.1., dealing with generator minimum voltage limitations, is vague with respect to what is required. It is not clear who would determine the minimum steady-state voltage limitations for all generators, and for what conditions. Note that it may be difficult to obtain some information from IPP generating facilities.

Requirement R3.2.2. appears redundant with requirement R1.2.1 of FAC-008-1, which deals with Facility Ratings. Relay load limits are one component already considered in establishing facility ratings.

Requirement R3.3.2.1., which deals with the amount and duration of Consequential Load loss, cannot be addressed adequately. Because an outage might be caused by a

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

transitory event with quick restoration of the outaged facility, or be caused by extensive damage requiring lengthy repairs, there would be no single value for expected duration for any given outage event in the planning horizon. Therefore, this requirement should be removed from TPL-001-1.

Requirement R3.3.2.2, describing permissible actions following single contingency events to meet performance requirements, should be removed from TPL-001-1. System adjustments following single contingencies should not be permitted to meet system performance requirements. For similar reasons, Requirement R3.5, describing generator adjustments permissible as responses to single and multiple contingencies, should be modified to remove the reference to single contingencies.

What additional single contingencies would there be that should be considered in Requirement R3.3.3?

Consequential generation loss needs to be considered in Requirement R3.6 for those generators directly connected (through transformation) to transmission lines.

Interconnection requirements establish that generators must have low-voltage ride through capability. It is not clear how is the transmission planner performing the studies would be able to consider this capability in Requirement R4.3.

In Requirement R6, there is no longer a requirement to send the Planning Assessment and Corrective Plan to the regional entities, but to the Reliability Coordinators instead. Why has this change been made? RTOs should not be involved in assessing compliance.

In reference to Table 1, bullet point #3, it is not clear how voltage instability, cascading outages, or uncontrolled islanding would be determined under steady state conditions.

Under Table 1, P1, cutting of firm transfers is not permitted as a response to a single contingency. However, it is not clear whether, in preparation for a subsequent contingency, reduction in firm transfers would be permitted. Reduction in firm transfers should be permissible in this instance.

In Table 1, for contingency categories P5 and P8, how would loss of a transmission circuit above 300 kV followed by loss of a transmission circuit below 300 kV be handled?

Under the Extreme Event Description section of Table 1, note that item 3e. is a duplicate of item 3c. One of these can be deleted. Also, for items 3d. and 3f. the notation regarding early shutdown of nuclear facilities for tornadoes is not realistic. The current state of the art of weather prediction does not permit adequate forecasting of tornadoes a day or more ahead of time which might be a cause for concern for a particular nuclear facility.

With respect to Table 2, contingency types P5 and P8, it would seem that events should include the same items as shown for contingency type P4.

In Table 2, for contingency types P1, P3, P4, P5, P8, and P9, clarification is needed as to whether distribution transformers (138-69 kV or 138-34.5 kV, for example) would be included in the events, or whether the transformers mentioned would be restricted to transmission transformers.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

For the various stability scenarios, note that Consequential Load Loss would be a function of how System protection equipment is set up for particular scenarios. Delayed clearing time/Zone 2 clearing times could result in load dropped that would not have been dropped for events cleared in primary clearing time.

In Table 2, Note 1 ii., is it the intent of the drafting team to require dynamic model representation of relaying equipment?

General comments:

We are not sure that a wholesale replacement of the existing standards TPL-001-0 through TPL-004-0 is required. We agree that additional clarification is needed for some items, and particularly for the study assumptions that go into the development of models to be used for the performance testing, but we do not agree that the proposed replacement standard provides that necessary clarification. Further, we believe that the replacement standard relies too much on the accompanying tables. More text needs to be included in the standard regarding the system performance requirements.

There is a lot of subjectivity involved in developing the study assumptions that need to be considered in the sensitivity models for study. How can we be sure that one or more of the sensitivity requirements in R2.1.3 stated for consideration are of the same level of importance by both auditors and those performing the studies? We are interested to see what the measures for all the requirements of the standard will be when they are developed.

Additional planning standard requirements for the EHV system to meet all N-2 conditions without dropping some load will require significant material changes, where feasible. We do not believe that the significant additional costs required for compliance would produce tangible benefits and a corresponding significant improvement in system reliability. What is the justification for the separate treatment for the EHV (>300 kV) facilities? One obvious effect of such requirements is to create a bias against any straight bus configuration for facilities above 300 kV. As stated in response to Question 25, there are existing facilities which cannot be converted from their present configuration. For those facilities which could be upgraded, an implementation period of several years would be needed to meet such requirements.

Meeting the requirements of this standard should not be a full time job. There are many more planning activities that need to be performed other than simulation testing to demonstrate compliance. The existing TPL standards require a significant manpower effort to perform the required studies and develop the planning assessment and corrective action plan. We are concerned that the replacement standard, as proposed, will create an even greater burden on the transmission owners without a commensurate benefit to the system reliability.

It is not within NERC's or ERO's scope of responsibility to address load loss. The focus of the standard should be on the system capabilities and not how much local load is dropped for a substation outage in a defined service area. A few reports showing the resultant bus voltages and facility loadings on a percentage basis for all single and a the more severe multiple contingency events, including operator or automatic mitigation procedures, should be adequate to demonstrate compliance.

**Comment Form for First Draft of TPL-001-1 — Transmission System
 Planning Performance Requirements**

Please use this form to submit comments on the proposed draft of TPL-001-1. Comments must be submitted by **Friday, October 26, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "TPL-001 Draft 1" in the subject line. If you have questions please contact Ed Dobrowolski at ed.dobrowolski@nerc.net or by telephone at 609-947-3673.

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment: Consider replacing "computer" with "model".</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment: Consider replacing "Consequential" with better wording (no specific suggestion to offer at this time).</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q6. Comment: Consider replacing "Non-Consequential" with better wording (no specific suggestion to offer at this time).	
Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment:	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q9. Comment:	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment:	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.
- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment: Consider requiring a minimum of two sensitivity cases.

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment: Consider requiring that the most severe sensitivity cases be included in the studies as determined by the entities conducting the studies.

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment: We concur with the use of sensitivity studies, but object to the requirement on what sensitivities to include. The flexibility to determine if sensitivity studies are appropriate, and the flexibility to choose what parameters are appropriate to study for sensitivity should be left open. R2.4.3 as written is restrictive to certain sensitivities and should not be.

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment: Consider requiring the same sensitivity analysis that is conducted under the near-term studies.

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No

Comment: Consider requiring that problem contingencies be simulated on base case that models the lower load level that would result with the DSM implemented.

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment: Consider limiting study area to immediately adjacent systems.

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment: Consider adding clear definition of "proposed" and "committed" projects (definition may impact response to this question).

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment:

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to "raise the bar." Strengthening the planning standards in selected areas is necessary to maintain a reliable Bulk Electric System that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the standard drafting team attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

The standard drafting team is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the standard drafting team to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by loss of another Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	Consider adding clear definition of "system adjustments", including the amount of time permitted to implement prior to the loss of the second facility.
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	Consider adding clear definition of "system adjustments", including the amount of time permitted to implement prior to the loss of the second facility.
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	Consider adding clear definition of "system adjustments", including the amount of time permitted to implement prior to the loss of the second facility.

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment: Consider adding clear definition of "bus tie breaker" and "non-bus tie breaker".

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No

Comment: Consider adding clear definition of "bus tie breaker" and "non-bus tie breaker".

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards — P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No

Comment:

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No

Comment:

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment:

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment: Extreme Event #9 in Table 2 has 3-phase fault and loss of all generating units at a station. Was this left in by mistake? This type of scenario could conceivably lead to low interconnection frequency or cascading due to consequent transmission overloading or low voltage, and could be studied by dynamic simulation. There have been a number of just such generation loss events as this in the past.

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment: The statements of fact in the question may be true for some study areas, but not necessarily for all. Requiring this type of load representation when it might not be appropriate to the study is excessively burdensome. This is a judgment better left to those conducting the studies. The percentage of load to be so represented, the extent of the study area over which to apply induction machine representations, and the specific modeling parameters are all judgements just as important as whether or not to

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

include this type of representation. There is a limit as to how far a standard can replace engineering judgment and that limit is reached here.

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment: The existing TPL standards imply that generator tripping is not permissible in connection with Category B events in that footnote b does not mention it, whereas it is mentioned in connection with Category C events in footnote c. Generation is a system resource and should be protected against the more common single contingency transmission events. We agree with the status quo on this issue being maintained in the new standard, with the provision for regional variance in R3.6. The provision for manual and automatic runback in R3.5 is okay. We also agree with manual adjustments remaining acceptable in response to any contingencies in the new standard consistent with C3 in existing TPL-003.

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control. The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment: Question: Why would a runback scheme be needed to move from an emergency state to a normal state when that could be accomplished by regular redispatch?

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Yes No

Comment: Ensure that the scheme is enabled to automatically runback for the problem conditions.

The standard drafting team has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment: As long as they are automatic.

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment: Should be allowed as long as they have been approved by the applicable Regional Reliability Organization.

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment: They include redundancy and their failure does not result in cascading.

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment:

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment:

Q43. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Yes No

Comment: (1) Consider clarifying system performance requirements that would be applicable during (a) the first two minutes after the system disturbance when slow-acting automatic system adjustments (such as the operation of motor-operated-air-break switches that are relayed to sectionalize the faulted segment of a multi-terminal circuit; the changing of taps on tap-changing-under-load transformers; the switching of capacitor banks; etc.) would not allowed to be considered, (b) the next three minutes (two to five minutes after the system disturbance) when these slow-acting automatic system adjustments would be allowed to be considered, (c) the next twenty-five minutes (five to thirty minutes after the system disturbance) when manual system

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

adjustments would be allowed to be considered, and (d) the time period beyond thirty minutes after the system disturbance when no system adjustments of any kind would be allowed to be considered.

(2) Consider clarifying which functional entity is expected to provide what information specified in this standard, especially in requirement 1.

(3) Consider clarifying the need for functional entities to provide competitive sensitive information such as planned outages.

(4) The system stability study documentation requirements R2.4 and R4.5 do not specify a level on the scope of studies or indicate the extent of coverage across a system required for acceptability. A reasonable scope of such studies might include studies of a system nature in association with dynamic devices, or voltage collapse or cascading scenarios, but what else would be required? Or, how much more stability study documentation beyond what is necessary to comply with TPL-001 through 004 would be required? Specific comments regarding R2.4 are as follows: what does "address" all five years mean? How much of the system do you need to study (for example, do you need to apply faults at every bus)? Again, you wouldn't know how much studying needs to be done before this requirement is satisfied. In R2.4.1 and R2.4.2, depending upon the study at hand, some other load condition such as shoulder peak may be more appropriate. Why should you be required to do peak and off-peak cases in such an instance? In R2.4.3 you are forced into doing at least one of the sensitivity studies listed (i.e., "to reflect one or more of the following conditions..."). Is this intentional? Depending upon the study at hand, none of these may be worthwhile doing, and there may be some other parameter that would be better looked at for sensitivity purposes. Existing TPL-001 through 004, Table 1, Category C3 requires any combination of generator, transmission line, transformer, or HVDC pole block in succession. The new standard excludes several of these combinations from being required in P4, P5, P8 and P9. Is this an intentional exclusion? If so, why? The standard should state explicitly that existing generation does not need to be studied unless R2.5.1 or R2.5.2 apply.

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0 and TPL-004-0. The SDT has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the SDT are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890 and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The SDT did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0 and TPL-004-0. The SDT organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The SDT determined that the requirements and analysis for Steady State are different from those for stability. As such, the SDT separated the analysis requirements and created two performance requirement tables.

The SDT recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The SDT has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The SDT has not addressed Measures, Risk Factors, Violation Severity Factors or Time Horizons at this time. These will be addressed when the SDT has better defined the requirements of the standard.

For questions where you agree with the SDT, please state that you agree and if available, please provide supporting documentation. If you disagree with the SDT, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

To improve the standard, the SDT would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the SDT is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<p><input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.</p>
<p>Q1. Comment: This should not be a defined term in the Glossary, instead there should be a Standard written that provides the industry with the requirements for completing a Base Case Study. This is the first step in completing the Transmission Studies required in TPL-001. There is no guarantee that the rules used by the transmission planners for the base case studies are done in a reliable manner. The Standard needs to be expanded to insure oversight by the compliance monitors to ensure that the base case is sound from a reliability perspective. Also, both reliability and transparency require that the results of the base case study along with the assumptions used to develop the study must be shared with responsible entities within contiguous areas of the BES, not just with contiguous Planning Coordinators and Transmission Planners. To insure consistent results, the Standard should require that a properly conducted Base Case Study be based on agreed rules for conducting such studies within each interconnection and use of consistent data/assumptions by other entities in the region; otherwise, the results of each PC's and TP's planning horizon studies and the operation planning studies will be brought into question.</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<p><input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.</p>
<p>Q2. Comment: This definition will help define what cascading outage is. There is</p>	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

<p>confusion in the industry and FERC as to “what is a cascading outage.” The planning process needs to address this confusion and define exactly what a cascading outage consists. Some want a cascading outage to be when loads beyond the primary or secondary protection equipment are dropped.</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<p><input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.</p>
<p>Q3. Comment: The definition is needed; however, this term is dependent on a clear definition of Planning Events, which does not exist.</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<p><input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.</p>
<p>Q4. Comment: This definition is needed to eliminate the confusion that exists in the industry.</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers Years One through five.</p>	<p><input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.</p>
<p>Q5. Comment: This definition is needed to eliminate the confusion that exists in the industry.</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<p><input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.</p>
<p>Q6. Comment: This definition should go beyond just saying “Load loss other than Consequential Load Loss.” Recommend adding the following: “. . . including Load Loss that occurs through planned manual (Transmission Operator, Distribution Provider, and so on) operation or planned automatic operation of load shedding equipment such as under-frequency load shedding devices or Special Protection Systems.”</p>	
<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.</p>	<p><input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.</p>
<p>Q7. Comment: This is too general. Just about any kind of review will qualify as a Planning Assessment. Suggested definition: “Documented evaluation of future Bulk Electric System needs by the use of performance studies such as NERC Steady State Transmission Studies or Plant Stability Studies conducted in accordance with the NERC Reliability Standards.”</p>	
<p>Q8. Planning Events: Events which require Transmission system performance requirements to be met.</p>	<p><input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.</p>
<p>Q8. Comment: What are “performance requirements?” This is too general a statement to be of value for writing specific standards.</p>	
<p>Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.</p>	<p><input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.</p>
<p>Q9. Comment: Insert “electric generating” prior to “plant” for clarity. It is unclear as to the intent of this statement. The Standard should require the Transmission Planner to consider contingencies in the vicinity of a particular electric generation plant. However,</p>	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

the ultimate goal of the “Stability Study” is to determine the stability of the BES and not just the “electric generation plant.” It is recommended that this be rewritten to make clear the intent of this statement.	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment: This is a very clear definition that can be used in Standards. The author did a good job of using defined terms in this definition.	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input type="checkbox"/> Agree. <input checked="" type="checkbox"/> Do not agree.
Q11. Comment: There is a term in the Glossary that is “Operation Plan;” however, there is not a term defining Operations Planning. It is recommended that the SDT drop the last sentence and define the term Operations Planning for the Glossary. Change “their” to “its.”	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii “Sensitivity studies and critical system conditions”, FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The SDT has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity (ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.
- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment: The term Base Case should not be used in this manner. The conditions of the Base Case Study should be in a Standard to insure that all sensitivity cases are covered.

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a “reasonably stressed” case?

Yes No

Comment: The Standard should indicate a list that says “the list will include but not be limited to:” and then list the minimum necessary to adequately cover the changes in the study.

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment: This is absolutely necessary; it will help with the operational planning that will be needed next. In addition, it will help to determine the amount of study uncertainty that the Transmission Planner believes will be in the plan. This is very important for the Year One.

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year 6 and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment: The sensitivity study of year 6 and beyond is of little value. The uncertainty (standard deviations) in the input assumptions used to complete the studies for 6 years and longer are so large it would not provide useful answers to make sound decisions regarding the need to build, remove, or improve BES facilities.

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If Yes, please comment on how the impact of DSM should be included.

Yes No

Comment: This is a conditional Yes. The Resource Planner or Transmission Planner must provide assurance that the specific "Demand" reduction that is incorporated into the scenario analyses will actually be reduced through either customer action or direct load shedding by the Balancing Authority. This type of controllable "Demand" does exist, but it is rare that planners and operators actually have such resources in their portfolios to help with System Deficiencies.

Q17. Requirement R2.7.2: Such Corrective Action Plans shall "Be added to study cases and the cases re-tested to show that the System with planned additions meets the performance requirements in the tables". Should new studies, including the facilities comprising the Corrective Action Plan, be performed to assess System normal performance and Contingency response for conditions that previously resulted in the System deficiencies (without the planned additions) and also demonstrate that the changes would not result in inadvertent negative impacts on the System. If you "agree", please comment on how a study area should be determined.

Yes No

Comment: This is necessary to insure the planners did not accidentally take the system and the future operation of the system from the frying pan into the fire.

Q18. Requirement R2.7.3: The standard calls for a differentiation between committed and proposed projects. Do you agree that they should be treated separately? If not, please state why not.

Yes No

Comment: While it is good to know the difference, it should be made clear in the Standard that if a project is listed as committed, it may be changed the next year to proposed project. Definitions for "committed" and "proposed" are needed to ensure consistent data/assumptions within each region.

Q19. Requirement R2.7.4: For such Corrective Action Plans "Committed projects shall not be removed without documentation to show that the revised plan meets the performance

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

requirements". Do you agree or disagree with this requirement? If you disagree, please explain why.

Yes No

Comment: It may be necessary, as a band-aid-type substitute, to replace a committed project with a Remedial Action Scheme (RAS)/Special Protection Systems in lieu of new facilities. Whatever the revised plan, it must be shown to meet the performance requirements.

D. Performance Requirements

The proposed revised planning standard (TPL-001-1) incorporates a number of changes in requirements as compared to the current planning standards (TPL-001-0 through TPL-004-0), which it is expected to replace. Among other things these changes are intended to clarify the standard, address issues described by FERC, and, in particular, to “raise the bar.” Strengthening the planning standards in selected areas is necessary to maintain a reliable BES that is up to the challenges of the 21st Century. In proposing the requirements in this draft, the SDT attempted to balance the value of increased reliability against any potential increase in work and costs to meet the new proposed standard.

The SDT is seeking input from the industry to determine whether a proper balance has been achieved. The areas where material changes are proposed in this draft are enumerated below, and questions are posed by the SDT to obtain industry comment. In formulating your responses, please keep in mind that material changes in the final standard will be accompanied by a transition plan to provide for an orderly implementation of the final standard.

The performance requirements relative to Non-Consequential Loss of Load for the following events enumerated in the two tables can be considered more stringent than the existing TPL Standards. Furthermore, the proposed standard is based on an assumption that performance requirements for EHV facilities should be more stringent than for lower voltage facilities.

Do you agree that Non-Consequential Loss of Load should not be permitted for the following events? If you disagree, please provide a reason for your disagreement.

Event	Agree or Disagree	Comment
Q20. P2-1: Loss of bus section (SLG for stability) above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	Note to APPA members – Please examine closely and give us specific comments on Q20 – Q29. If you disagree we need to know.
Q21. P5-1: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment ¹ followed by	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

loss of another Transmission circuit		
Q22. P5-2: For facilities above 300 kV, loss of a Transmission circuit followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q23. P5-3: For facilities above 300 kV, loss of a transformer with low side voltage rating above 300 kV followed by System adjustment followed by loss of another transformer	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

¹System adjustment can be manual or automatic.

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q24. Loss of non-bus tie breaker (above 300 kV) due to internal fault

Yes No

Comment:

The proposed standard is based on an assumption that performance requirements for non-bus tie EHV breakers should be distinguished from other breakers and that performance requirements for EHV facilities should be more stringent than for lower voltage facilities. Do you agree that Non-Consequential Loss of Load should not be permitted for this event?

Q25. P3-1: Loss of (SLG for stability) either a generator, a Transmission circuit, a transformer, or a bus and a stuck non-bus tie breaker (above 300 kV)

Yes No

Comment:

The proposed standard is based on an assumption that the following events are relatively high probability events and, therefore, Non-Consequential Loss of Load should not be permitted. Do you agree? If you disagree, please provide a reason for your disagreement.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Event	Agree or Disagree	Comment
Q26. P4-1: Loss of a Generator followed by System adjustment ¹ followed by loss of another Generator	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q27. P4-2: Loss of a generator followed by a System adjustment followed by the loss of a monopolar DC line	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q28. P4-3: Loss of a generator followed by System adjustment followed by loss of a Transmission circuit	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	
Q29. P4-4: Loss of a generator followed by System adjustment followed by loss of a transformer with low side voltage rating above 300 kV	<input checked="" type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.	

The performance requirement for the following event may be considered less stringent than the existing TPL Standards - P2-3: Loss of a single pole of a DC line. Interruption of firm transactions (without Loss of firm Load) if the transaction is dependent on the faulted DC line is now allowed for this initiating event/Contingency.

Q30. Do you agree that interruption of any firm transfers that are dependent on the outaged DC line that is taken out of service should be permitted?

Yes No

Comment:

E. Stability

Q31. The proposed standard is based on an assumption that steady state analysis and stability analysis are different from each other and that therefore, two tables of Contingencies and performance requirements were needed. It is also based on an assumption that stability study requirements should be clearly separated from the steady state study requirements. Do you agree with the action taken in separating stability analysis from steady state analysis? If not, please explain.

Yes No

Comment:

¹ System adjustment can be manual or automatic

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q32. The SDT has added requirements for plant stability studies and has drawn a distinction in these studies from System stability studies. Do you agree with this approach? If not, please explain.

Yes No

Comment: This has been needed for some time.

Q33. The existing TPL-004-0 standard has a requirement to consider the Loss of all generating units at a plant, but it was not clear whether this requirement should apply to stability studies. The SDT did not include this requirement in the stability table, because it is hard to envision a condition when all units would trip simultaneously within the timeframe of a stability simulation. Do you think this condition should be required in stability analysis of extreme events? If not, please explain.

Yes No

Comment: This is a conditional Yes. If the plant design was such that a fault at the plant could remove all units, then all units should be considered. However, if the plant design is such that the likelihood of all plants going down at one time is improbable, then the SDT's approach is very reliable.

Q34. There are an increasing number of events with slow voltage recovery after faults on the Transmission System. The dynamic behavior of induction motor loads is a major factor in this phenomenon. The proposed standard therefore requires that the load model for stability studies of peak Load conditions include the dynamic effects of induction motors. Do you agree with this requirement? If not, please explain?

Yes No

Comment: The SDT is correct to include the effects of induction motors in simulating the loads. Voltage issues are and will continue to become more critical in the operation of the BES as time goes by. It will be a big help to planners and operators to know the impacts of such loads.

Q35. What type of manual or automatic adjustments of generators should be allowed for single and multiple Contingencies?

Comment: I do not understand the question. Is this dealing with voltage adjustment or power adjustment?

F. Generation Runback and Tripping

The SDT has discussed the automatic and manual readjustments of generators that should be permissible for single contingencies and multiple contingencies. The existing TPL-001-0 through TPL-004-0 standards through footnote (a) of Table I could include emergency ratings applicable for short durations as required to permit operating steps necessary to maintain system control.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

The footnote is silent about allowable generation adjustments in response to the Category B events. However, it does indicate that system adjustments are permitted to prepare for the next Contingency. These system adjustments could include manual or automatic adjustments involving generation.

The SDT has learned that many transmission owners use System Protection Systems (SPS) or Remedial Action Schemes (RAS) to trip generation for single and multiple Contingency outage events to prevent overloads, low voltage, and instability in the Interconnected Transmission network for N-1 and N-2 events. In some cases, the RAS are used to prepare for the next Contingency; but in some cases, the RAS are used to simultaneously avoid exceeding emergency ratings.

Q36. The proposed standard allows generation runback after the disturbance that causes a single Contingency (or due to a single Contingency outage) to move the Interconnected Transmission System from an emergency state (within emergency ratings) to a normal state (within normal ratings), assuming that the disturbance does not result in instability? Do you agree? If not, please explain.

Yes No

Comment: However, it should be pointed out that RAS are band-aid solutions to building needed BES infrastructure. Experience has shown that an interconnection can have so many RAS that one RAS will counter another RAS designed for another problem in the interconnection. This problem requires additional study by a NERC task force.

Q37. Since emergency ratings are thermal ratings, should this standard allow an automatic generation runback scheme (that is initiated immediately after the disturbance causing the single Contingency) to prevent thermal overloads (assuming that the disturbance does not result in instability)? If yes, what are the conditions that must be met in order to allow such a runback scheme to meet the System performance criteria for single Contingencies? Please explain the reason for your answer.

Yes No

Comment: Care must be taken to insure runbacks of one event will not cancel the effects of other runback plans in the same interconnections.

The SDT has considered that RAS or SPS may be allowable under certain situations for single Contingencies, but proposes that their use should be limited.

Q38. Do you agree that RAS or SPS may be allowed for single Contingencies? If not, please explain.

Yes No

Comment: As the SDT has said under certain situations.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Q39. Please describe the limitations that you believe should be placed on the use of RAS or SPS for single Contingency events.

Comment: See Question 36.

Q40. When RAS or SPS are allowed, what conditions should be met when these systems are used in system adjustments to meet performance requirements?

Comment: Maintain system stability and prevent the loss of load.

G. General Questions

Q41. If you are aware of any regional variances that would be required as a result of these standards, please identify them here.

Yes No

Comment: The WECC will probably have a couple.

Q42. If you are aware of any conflicts between the proposed standards and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify them here.

Yes No

Comment:

Q43. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Yes No

Comment: The Standards are a great start in getting a set of requirements in place that will provide a planning methodology that will be transparent to the Functional entities in the interconnections and will produce results that will permit reliable planning and operations of the BES.

Requirement 5 is a start at attempting to share the results of the planning studies with the correct entities. However, because this is such an important part of reliable planning, this requirement should be rewritten to be much more definitive and comprehensive. It is recommended the SDT review the FAC-014 Standard where this Standard deals with who is to receive the methodology for calculating SOLs. The SDT needs to insure that the Transmission Planners and Planning Coordinators share their Near-Term Planning Horizon Studies with the Transmission Operators (Operation Planners) and the appropriate Regional Entity Planning Committees and Operating Committees.

It is also recommended that the SDT remove all Requirements that are subjective and cannot be measured. For example, who must the Transmission Planner share information

with? Requirement R5.2 states that information must be shared with Transmission Planners of neighboring impacted areas. A Compliance Monitor cannot determine if a neighbor is being impacted. In fact, from an enforcement perspective, if the involved parties must go before a Judge, who will determine if someone is impacted or not?

In addition, the assumptions the Transmission Planners and Planning Coordinators use to conduct the Studies are not required to be shared or posted. As an example, in some parts of the BES Transmission Planners and Planning Coordinators use Flowgate Methodology to study the BES, while others use Rated System Paths, and still others use Area Interchange (Network Methodology).

This standard needs to be modified to respond to several requests from Order 890 and Order 693. These Orders request that through the Standards, information be made available, posted, and shared with the appropriate reliability functions. This information includes the results of Planning Horizon Studies, Operating Horizon Studies, and eventually the determination of Available Transfer Capabilities. This information also includes, but is not necessarily limited to: how do the planners treat the “counter flows” in their studies, what are the generation and transmission planned outage schedules used in the planning studies, how are Network Loads and Network Facilities treated in planning studies; and how do the planners treat Grandfathered Transmission and Grandfathered Power and Energy Contracts in the planning studies?

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

Background

The purpose of this standard is to establish Transmission System planning performance requirements within the planning horizon to develop a Bulk Electric System that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies. This standard will replace TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team has not yet addressed TPL-005-0 and TPL-006-0, but will address these two standards during the next phase of the drafting process.

The major objectives of the standard drafting team are to:

- 1) Ensure the standard is complete and the requirements are set at an appropriate level to ensure reliability (Not Least Common Denominator)
- 2) Ensure that the standard is enforceable by having clearly defined requirements with unambiguous language
- 3) Address the issues raised by FERC Order 693, 890, and other applicable orders
- 4) Address the issues raised in the original Standards Authorization Request (SAR) and the Supplemental SAR.

The standard drafting team did not attempt to edit the existing standards but rather chose to write one standard that addresses all aspects of transmission planning in the existing TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0. The standard drafting team organized the new standard in the following sections:

- R1 – Modeling requirements
- R2 – Assessment and Corrective Plan requirements
- R3 – Steady State Analysis requirements
- R4 – Stability Analysis requirements
- R5 – Coordination requirements

The standard drafting team determined that the requirements and analysis for Steady State are different from those for stability. As such, the standard drafting team separated the analysis requirements and created two performance requirement tables.

The standard drafting team recognizes that this draft standard is a starting point for industry input into the standard and that there is still a lot of work required to complete the process. The standard drafting team has made many changes to clarify requirements, add requirements, and make some of the performance requirements stricter. The standard drafting team has not addressed Measures, Risk Factors, Violation Severity Factors, or Time Horizons at this time. These will be addressed when the standard drafting team has better defined the requirements of the standard.

For questions where you agree with the standard drafting team, please state that you agree and if available, please provide supporting documentation. If you disagree with the standard drafting team, please explain why you disagree and provide data to support your position, such as outage data or analysis. If you believe that we have made a performance requirement too strict please provide supporting documentation. If applicable, please include the approximate cost in man-hours for additional studies and/or cost in \$Millions for additional transmission investment to meet the new requirements or the stricter requirements. If you believe that the standard should be stricter, please provide the rationale along with any supporting data, including existing practices, cost estimates or additional analysis.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

To improve the standard, the standard drafting team would appreciate responses to as many of these questions as you can answer.

A. New Definitions

Many of the concerns about the existing TPL standards come from the fact that a number of generally understood concepts are embedded in undefined terms, tables, and footnotes. To clarify some of these concerns, the standard drafting team is proposing new definitions. Please indicate whether you agree with the following proposed definitions and provide proposed changes to the definitions if you disagree:

Definition	Agree or Disagree
<p>Q1. Base Case: Computer representation of the projected initial or starting Transmission System conditions for a specific point in time. Each base case reflects the forecasted Load at each bus (or node) on the interconnected Transmission System, the transmission facilities which deliver the generation and reactive resources to the connected Load, and the generation dispatch including firm transaction obligations assumed to supply the connected Load. The models also reflect facility ratings in accordance with FAC-008 & FAC-009.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q1. Comment:</p>	
<p>Q2. Consequential Load Loss: Load that is no longer served because it is directly connected to an element(s) that is removed from service due to fault clearing action or mis-operation.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q2. Comment:</p>	
<p>Q3. Extreme Events: Events which are more severe than Planning Events and have a low probability of occurrence.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q3. Comment:</p>	
<p>Q4. Long-Term Transmission Planning Horizon: Transmission planning period that covers years six through ten or beyond.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q4. Comment:</p>	
<p>Q5. Near-Term Transmission Planning Horizon: Transmission planning period that covers years One through five.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q5. Comment:</p>	
<p>Q6. Non-Consequential Load Loss: Load loss other than Consequential Load Loss. For example, Load loss that occurs through manual (operator initiated) or automatic operations such as under-voltage Load shedding, under-frequency Load shedding, or Special Protection Systems.</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
<p>Q6. Comment:</p>	
<p>Q7. Planning Assessment: Documented evaluation of future Bulk Electric System needs by the use of performance studies that cover a range of assumptions regarding system conditions, time</p>	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not

frames, future plans including capital reinforcements and operating procedures and other factors, such as asset conditions and age.	agree.
Q7. Comment:	
Q8. Planning Events: Events which require Transmission system performance requirements to be met.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q8. Comment:	
Q9. Plant Stability Study: Study of an individual plant's Stability for various Contingencies in the vicinity of the plant; concerned with the effect on the System of the generating units' loss of synchronism and the damping of the generating units' power oscillations.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q9. Comment:	
Q10. System Stability Study: Study of the System or portions of the System to ensure that angular Stability is maintained, inter-area power oscillations are damped, and voltages during the dynamic simulation stay within acceptable performance limits.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q10. Comment:	
Q11. Year One: The first year that a Transmission Planner is responsible for studying. This is further defined as the planning window that begins the next calendar year from the time the Transmission Planner submits their annual studies. Analysis conducted for time horizons within the calendar year from the study publication are assumed to be conducted under the auspices of Operations Planning.	<input type="checkbox"/> Agree. <input type="checkbox"/> Do not agree.
Q11. Comment:	

B. Sensitivity Studies

The draft planning standard includes the requirement, as specified in FERC Order 693, that planning decisions be based on a portfolio of analyses. In section 12.a.ii "Sensitivity studies and critical system conditions" FERC provided direction to consider a full range of variables considered to be significant that need to be assessed and documentation provided that explains the rationale for the selection of variables assessed.

In addition to the firm obligation scenario, the portfolio of analyses should be supplemented to include information from sensitivity analysis. The sensitivity analysis should be developed using additional cases that simulate reasonably stressed system conditions. The standard drafting team has included several parameters that can be varied to create the requisite sensitivity case(s). The draft standards specify that the sensitivities reflect one or more of the following conditions and that documentation be provided explaining the rationale for selecting the sensitivity(ies) employed. The parameters that should be varied include:

- Higher or lower Load forecasts from the Base Case with variability of Load/demand and Load power factors due to season, weather, or time of day.
- Modification of expected transfers.
- Unavailability of long lead time facilities.
- Variability and outages of Reactive Resources.
- Generation additions, retirements, or other dispatch scenarios.

Comment Form for First Draft of TPL-001-1 — Transmission System Planning Performance Requirements

- Decreased effectiveness of controllable Loads and Demand Side Management.
- Modification of planned Transmission outages

To help focus industry discussion, please respond to the questions below:

Q12. Should the standard provide more specific direction regarding the number of sensitivity cases that need to be developed?

Yes No

Comment:

Q13. Should the standard specify the required changes, such as changes in expected transfers, load forecasts, generation patterns, etc., from the study case to be considered a "reasonably stressed" case?

Yes No

Comment:

Q14. The SDT proposes to require the use of sensitivity studies for Near-Term Transmission System Planning Horizon stability analysis. Do you concur with the use of sensitivity analysis in dynamic studies?

Yes No

Comment:

Q15. The draft TPL standard does not require the use of sensitivity studies for the Long-Term Transmission System Planning Horizon (year six and beyond) studies. Do you concur with this approach or should there be some level of sensitivity analysis required for the long-term period?

Yes No

Comment:

C. Corrective Action Plans

Requirement R2.7 of the standard states that when analysis shows that the performance requirements in Table 1 and Table 2 are not fully met, a Corrective Action Plan that utilizes all or some of the Transmission System enhancements, generation additions, DSM, new technologies and Operating Procedures shall be included in the Planning Assessment. This Corrective Action Plan should ensure that upon its implementation the identified system deficiencies will be corrected so that the performance requirements in Table 1 and Table 2 will be met. Furthermore, studies included in the Planning Assessment should demonstrate that this is indeed the case.

Q16. Requirement R2.7.1: Such Corrective Action Plans shall "Identify System deficiencies and the associated actions needed to achieve required System performance including Transmission and generation improvements, DSM, new technologies, or Operating Procedures including the duration of Interim Operating Procedures". System deficiencies may be corrected using an integrated plan, i.e., an optimal mix of Transmission, generation, DSM and Operating Procedures. Should DSM be considered in conjunction with other measures in developing Corrective Action Plans? If yes, please comment on how the impact of DSM should be included.

Yes No
